JANUARY, 1917

No. 1

# EXPERIMENT STATION RECORD

WASHINGTON  
GOVERNMENT PRINTING OFFICE  
1917

# U. S. DEPARTMENT OF AGRICULTURE.

## Scientific Bureaus.

WEATHER BUREAU—C. F. Marvin, *Chief*.  
 BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.  
 BUREAU OF PLANT INDUSTRY—W. A. Taylor, *Chief*.  
 FOREST SERVICE—H. S. Graves, *Forester*.  
 BUREAU OF SOILS—Milton Whitney, *Chief*.  
 BUREAU OF CHEMISTRY—C. L. Alsberg, *Chief*.  
 BUREAU OF CROP ESTIMATES—L. M. Estabrook, *Statistician*.  
 BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.  
 BUREAU OF BIOLOGICAL SURVEY—E. W. Nelson, *Chief*.  
 OFFICE OF PUBLIC ROADS AND RURAL ENGINEERING—L. W. Page, *Director*.  
 OFFICE OF MARKETS AND RURAL ORGANIZATION—C. J. Brand, *Chief*.

STATES RELATIONS SERVICE—A. C. True, *Director*.

OFFICE OF EXPERIMENT STATIONS—E. W. Allen, *Chief*.

## THE AGRICULTURAL EXPERIMENT STATIONS.

### ALABAMA—

College Station: *Auburn*; J. F. Duggar.<sup>1</sup>  
 Canebrake Station: *Uniontown*; L. H. Moore.<sup>1</sup>  
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.<sup>1</sup>

### ALASKA—*Sitka*: C. C. Georgeson.<sup>2</sup>

### ARIZONA—*Tucson*: G. F. Freeman.<sup>2</sup>

### ARKANSAS—*Fayetteville*: M. Nelson.<sup>1</sup>

### CALIFORNIA—*Berkeley*: T. F. Hunt.<sup>1</sup>

### COLORADO—*Fort Collins*: C. P. Gillette.<sup>1</sup>

### CONNECTICUT—

State Station: *New Haven*; } E. H. Jenkins.<sup>1</sup>  
 Storrs Station: *Storrs*; }

### DELAWARE—*Newark*: H. Hayward.<sup>1</sup>

### FLORIDA—*Gainesville*: P. H. Rolfs.<sup>1</sup>

### GEORGIA—*Experiment*: H. P. Stuckey.<sup>2</sup>

### GUAM—*Island of Guam*: A. C. Hartenbower.<sup>2</sup>

### HAWAII—

Federal Station: *Honolulu*; J. M. Westgate.<sup>2</sup>  
 Sugar Planters' Station: *Honolulu*; H. P. Agee.<sup>1</sup>

### IDAHO—*Moscow*: J. S. Jones.<sup>1</sup>

### ILLINOIS—*Urbana*: E. Davenport.<sup>1</sup>

### INDIANA—*La Fayette*: A. Goss.<sup>1</sup>

### IOWA—*Ames*: C. F. Curtiss.<sup>1</sup>

### KANSAS—*Manhattan*: W. M. Jardine.<sup>1</sup>

### KENTUCKY—*Lexington*: A. M. Peter.<sup>2</sup>

### LOUISIANA—

State Station: *Baton Rouge*; }  
 Sugar Station: *Audubon Park*, } W. R. Dodson.<sup>1</sup>  
*New Orleans*; }  
 North La. Station: *Calhoun*; }

### MAINE—*Orono*: C. D. Woods.<sup>1</sup>

### MARYLAND—*College Park*: H. J. Patterson.<sup>1</sup>

### MASSACHUSETTS—*Amherst*: W. P. Brooks.<sup>1</sup>

### MICHIGAN—*East Lansing*: R. S. Shaw.<sup>1</sup>

### MINNESOTA—*University Farm*, *St. Paul*: A. F. Woods.<sup>1</sup>

### MISSISSIPPI—*Agricultural College*: E. R. Lloyd.<sup>1</sup>

### MISSOURI—

College Station: *Columbia*; F. B. Mumford.<sup>1</sup>  
 Fruit Station: *Mountain Grove*; Paul Evans.<sup>1</sup>

### MONTANA—*Bozeman*: F. B. Linfield.<sup>1</sup>

### NEBRASKA—*Lincoln*: E. A. Burnett.<sup>1</sup>

### NEVADA—*Reno*: S. B. Doten.<sup>1</sup>

### NEW HAMPSHIRE—*Durham*: J. C. Kendall.<sup>1</sup>

### NEW JERSEY—*New Brunswick*: J. G. Lipman.<sup>1</sup>

### NEW MEXICO—*State College*: Fabian Garcia.<sup>1</sup>

### NEW YORK—

State Station: *Geneva*; W. H. Jordan.<sup>1</sup>  
 Cornell Station: *Ithaca*; A. R. Mann.<sup>2</sup>

### NORTH CAROLINA—

College Station: *West Raleigh*; } B. W. Kilgore.  
 State Station: *Raleigh*; }

### NORTH DAKOTA—*Agricultural College*: T. P. Cooper.<sup>1</sup>

### OHIO—*Wooster*: C. E. Thorne.<sup>1</sup>

### OKLAHOMA—*Stillwater*: W. L. Carlyle.<sup>1</sup>

### OREGON—*Corvallis*: A. B. Cordley.<sup>1</sup>

### PENNSYLVANIA—

State College: *R. L. Watts*.<sup>1</sup>  
 State College: *Institute of Animal Nutrition*;  
*H. P. Armsby*.<sup>1</sup>

### PORTO RICO—

Federal Station: *Mayaguez*; D. W. May.<sup>2</sup>  
 Insular Station: *Rio Piedras*; W. V. Tower.<sup>1</sup>

### RHODE ISLAND—*Kingston*: B. L. Hartwell.<sup>1</sup>

### SOUTH CAROLINA—*Clemson College*: —

### SOUTH DAKOTA—*Brookings*: J. W. Wilson.<sup>1</sup>

### TENNESSEE—*Knoxville*: H. A. Morgan.<sup>1</sup>

### TEXAS—*College Station*: B. Youngblood.<sup>1</sup>

### UTAH—*Logan*: F. S. Harris.<sup>1</sup>

### VERMONT—*Burlington*: J. L. Hills.<sup>1</sup>

### VIRGINIA—

*Blacksburg*: A. W. Drinkard, Jr.<sup>1</sup>  
*Norfolk*: *Truck Station*; T. C. Johnson.<sup>1</sup>

### WASHINGTON—*Pullman*: I. D. Cardiff.<sup>1</sup>

### WEST VIRGINIA—*Morgantown*: J. L. Coulter.<sup>1</sup>

### WISCONSIN—*Madison*: H. L. Russell.<sup>1</sup>

### WYOMING—*Laramie*: H. G. Knight.<sup>1</sup>

<sup>1</sup> Director.

<sup>2</sup> Agronomist in charge.

<sup>1</sup> Acting director.

# EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Chief, Office of Experiment Stations.*  
Assistant Editor: H. L. KNIGHT.

## EDITORIAL DEPARTMENTS.

Agricultural Chemistry and Agrotechny—E. H. NOLLAU.	
Meteorology, Soils, and Fertilizers	{ W. H. BEAL. R. W. TRULLINGER.
Agricultural Botany, Bacteriology, and Plant Pathology	{ W. H. EVANS, Ph. D. W. E. BOYD.
Field Crops	{ J. I. SCHULTE. J. D. LUCKETT.
Horticulture and Forestry—E. J. GLASSON.	
Economic Zoology and Entomology—W. A. HOOKER, D. V. M.	
Foods and Human Nutrition	{ C. F. LANGWORTHY, Ph. D., D. Sc. H. L. LANG.
Zootechny, Dairying, and Dairy Farming	{ H. WEBSTER. M. D. MOORE.
Veterinary Medicine	{ W. A. HOOKER. E. H. NOLLAU.
Rural Engineering—R. W. TRULLINGER.	
Rural Economics—E. MERRITT.	
Agricultural Education—C. H. LANE.	
Indexes—M. D. MOORE.	

## CONTENTS OF VOL. 36, NO. 1.

Editorial notes:	Page.
The New York meeting of the American Association for the Advancement of Science.....	1
The adjustment of science to practice.....	2
Qualities and organization of research and experiment.....	5
Coordination in scientific effort.....	7
Recent work in agricultural science.....	12
Notes.....	98

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Studies in the physical chemistry of essential oils.....	12
Numerical relations among the rotatory powers of the compound sugars, Hudson.....	12
Isomeric alpha and beta hexacetates of $\alpha$ -glucoheptose, Hudson and Yanovsky.....	12
$\alpha$ -crotonic acid, a soil constituent, Walters and Wise.....	12
Biochemical changes in cotton seed in storage, Rather.....	12
Experiments upon the amylase of <i>Aspergillus oryzae</i> , Sherman and Tanberg....	13
Enzymes of the blood in the albumin and globulin fractions of the serum, Satta..	13
A nonspattering wash bottle, Clapp.....	13
Researches on quinazolins, XXXIII, Bogert and Scatchard.....	13
Kjeldahl modification for nitro substitution compounds, Cope.....	14
Apparatus for Kjeldahl determinations, Randall.....	14

	Page.
Sodium sulphate in Gunning modifications for determining nitrogen, Latshaw..	14
A modification of McCrudden's method for calcium, Winter.....	14
A table for values of carbon in carbon dioxide, Loomis.....	15
Rapid method for accurate determination of total carbon in soils, Salter.....	15
The reducing action of distillates from certain carbohydrates, Atkinson.....	15
The rate of ammonia distillation from water, Bruckmiller.....	15
Melting-point determination of fats and waxes, Golodetz.....	15
Detection of pigments in oleomargarine and butter, Palmer and Thrun.....	16
Estimation of polysulphide and thiosulphate in lime-sulphur solutions, Averitt.	16
Sulphur fungicides, Gray.....	16
Methods of preparation and relative value of Bordeaux mixtures, Butler.....	16
The sterilization of fruit and vegetables for the home.....	17
The sterilization of fruit and vegetables for the market.....	17
The recovery of potash from alunite, Waggaman and Cullen.....	17
Hemp hurds as paper-making material, Dewey and Merrill.....	17
Effects of moisture introduced into the digester in cooking soda pulp, Wells....	17

## METEOROLOGY.

Department of meteorology, Church, jr.....	17
A method of forecasting the maximum summer level in Lake Tahoe, Alciatore	18
The persistence of wet and dry weather, Newnham.....	18
Monthly Weather Review.....	19
The fertilizing value of rain and snow, Shutt.....	19
Meteorological observations at Massachusetts Station, Ostrander and Sims....	19

## SOILS—FERTILIZERS.

Soil survey of Jefferson County, Ark., Tillman et al.....	20
Kankakee County soils, Hopkins et al.....	20
Reconnaissance soil survey of part of north-central Wisconsin, Geib et al.....	20
Studies on soils, I, Rice.....	21
Studies on soil colloids. I, Flocculation of soil colloidal solutions, Wolkoff....	21
Bacterial numbers in soils at different depths and seasons, Waksman.....	21
Some factors that influence nitrate formation in acid soils, Fred and Graul....	22
Studies in sulfofication, Brown and Johnson.....	22
Some effects of litter on the fermentation of manure, Tottingham.....	23
Fertilizer experiments, Shutt.....	24
Protein decomposition in soils, Lathrop.....	25
Potash salts, 1915, Phalen.....	26
Oxidation of sulphur as increasing availability of phosphates, Lipman et al....	26
The influence of liming on the productiveness of certain soils, Shutt.....	26
Fertilizing materials, Shutt.....	27

## AGRICULTURAL BOTANY.

Agriculture and native vegetation in Peru, Cook.....	27
Vegetation of a desert mountain range as conditioned by climate, Shreve....	27
Characters of plants grown in salt water and heredity, Lesage.....	27
Dissimilarity in inheritance from different parts of plant, Bateson and Pellew..	27
A hybrid between <i>Tripsacum</i> and <i>Euchlæna</i> , Collins and Kempton.....	27
Patrogenesis in cross of <i>Tripsacum</i> and <i>Euchlæna</i> , Collins and Kempton.....	28
Influence of temperature on the growth of the root of <i>Pisum sativum</i> , Leitch..	28
The influence of temperature variations on the respiration of plants, Blanc....	28
The decrease of permeability produced by anesthetics, Osterhout.....	29
Swelling and germination of seeds, Traube and Marusawa.....	29
The influence of oxygenated water on germination, Demoussy.....	29
Studies on water transfer in plants, Jost.....	29
Studies on the decomposition of cellulose in soils, McBeth.....	30
The primary sugar of photosynthesis, Dixon and Mason.....	30
The biochemical function of magnesium in plants, Bernardini.....	30
The influence of various salts on the growth of soy beans, Shive.....	31
Studies in the nutritive relations of cultivated plants, Hiltner et al.....	31
Diastase activity and invertase activity of bacteria, Koch.....	31
Quantitative media for the estimation of bacteria in soils, Cook.....	31
A method for the renewal of plant nutrients in sand cultures, McCall.....	31
Preliminary revision of the genus <i>Inga</i> , Pittier.....	32

## FIELD CROPS.

	Page.
[Field crops work at the Canada stations and farms in 1914], Crisdale.....	32
[Work with field crops at Canada experimental farms in 1914], Graham et al....	33
Summary report of state cooperative experiment farms, 1915.....	33
Cereal experiments at the Akron field station, Akron, Colo., McMurdo.....	33
Cereal experiments at the Judith Basin substation, Mont., Donaldson.....	33
A pasture survey in southeastern Ohio, Hawthorne and Montgomery.....	34
Irrigation experiment with clover, sugar beets, potatoes, and wheat, Knight....	35
Varieties of cereal and forage crops and their improvement, Knight.....	36
The cultural value and identification of Spanish alfalfa, Gentner.....	36
Composition of the maize plant, Ince.....	36
Spacing experiment with Egyptian cotton, 1912, Balls and Holton.....	36
Sowing-date experiment with Egyptian cotton, 1913, Balls and Holton.....	37
Early and midseason potatoes at Wisley, 1915.....	37
Sugar beets for factory purposes, Shutt.....	37
Sudan grass in Kansas, Thompson.....	38
The time to seed wheat in Kansas, Call, Salmon, and Cunningham.....	38
Liming the wheat crop, Thorne.....	38
Seed analyses made during 1912-1915, Jagger and Stoddard.....	39

## HORTICULTURE.

Report from the division of horticulture for 1915, Macoun et al.....	39
[State insecticide and fungicide laws].....	39
The relation of fruit growing to soil fertility, Thompson.....	39
[The effect of site on blossom development and frost injury], Church, jr.....	40
Orchard rejuvenation in southeastern Ohio, Ballou.....	40
Variation of internal structure of apple varieties, Kraus.....	41
Pruning peach trees at different heights previous to planting, Blake.....	41
A financial statement of the experiment station peach orchard, McCue.....	42
Report of cranberry substation for 1915, Franklin.....	43

## FORESTRY.

Report of director of forestry of Philippine Islands for 1915, Sherfesee.....	44
Report on state nurseries and plantations, Brodrick et al.....	44
Report of the chief forest fire warden for the year 1915, Wirt.....	44
Grass and woodland fires in Texas, Foster.....	44
Importance of soil aeration in forestry, Hole.....	44
A preliminary study on the culture of exotic forest species in Italy, Pavari....	45
Notes on acacia, with description of new species, I, Maiden.....	45
Notes on Eucalyptus, with descriptions of new species, IV, Maiden.....	45
<i>Eucalyptus australiana</i> n. sp. and its essential oil, Baker and Smith.....	45
Notes on the tapping of Para rubber, Freeman.....	45
A new steam tree feller, Scrimgeour.....	45
Selling woodlot products on Michigan farms, Frothingham.....	45
Forest products of Canada, 1915.—Pulpwood.....	45
Proceedings of meeting of American Wood Preservers' Association, Angier.....	45

## DISEASES OF PLANTS.

Pathological plant anatomy, Küster.....	46
Tumors in plants, Smith.....	46
How to identify infectious plant diseases, Ashby.....	46
Report of the division of botany, Güssow.....	46
Notes on plant diseases of Connecticut, Clinton.....	47
Report on plant protection, Schaffnit and Lüstern.....	47
Administration report of the government mycologist for 1914-15, McRae.....	47
Septoria on barley, Johnson.....	48
Occurrence of yellow leaf rust of wheat in Salt Lake Valley, Utah, O'Gara....	48
<i>Cordyceps clavicipitis</i> n. sp., parasitic on ergot, Örtgren.....	48
Californian thistle rust, Cockayne.....	48
The dry rot disease of maize caused by <i>Diplodia zeae</i> , van der Bijl.....	48
Powdery scab of potato, Clinton.....	48
Seed and soil disinfectants for Rhizoctonia disease, Morse and Shapovalov....	49

	Page.
Potato spraying experiments, third report, Clinton.....	49
A new species of <i>Melanconium</i> parasitic on the tomato, Tisdale.....	49
Infection and resistance studies of <i>Phytophthora infestans</i> on tomato, Melhus... 49	49
Second progress report on disease resistance in tobacco, Johnson.....	50
Disinfection to overcome the root rot ( <i>Thielavia basicola</i> ), Barnet.....	50
Fire blight investigations, Gossard and Walton.....	50
Longevity of <i>Bacillus amylovorus</i> , Hotson.....	50
Arsenate of lead as a fungicide for apple scab, Morse.....	50
Irrigation and bitter pit, Brooks and Fisher.....	50
Blight-resistant roots—the first step toward pear blight control, Wisker.....	51
Further studies on plum wilt, Higgins.....	51
Summer sprays against American gooseberry mildew, Barker and Lees.....	51
[Fungus diseases of the cranberry], Franklin.....	51
Eradication on a large scale, Nelson.....	52
Diseases of plants caused by nematodes, Clinton.....	52
Cutting out chestnut blighted timber, Stoddard and Moss.....	52
A Gloeosporium on horse-chestnut shoots, Adams.....	52
Leaf fall of conifers, Neger and Fuchs.....	52
Tip burn in white pine, Burns.....	52
Eradication of <i>Cronartium ribicola</i> from European pine plantings, Rankin.... 53	53

## ENTOMOLOGY.

[Report of the] department of entomology, Doten.....	53
An attempt to redefine host relationships in entomophagous insects, Smith.... 53	53
Sprays and spraying, Paddock.....	53
Cost of dusting and spraying a New York apple orchard, Crosby.....	53
[Work with cranberry insects in 1915], Franklin.....	54
<i>Gonepteryx rhamni</i> and <i>Castnia thearon</i> in New Jersey, Weiss.....	54
Grasshopper control, Merrill.....	55
Notes on <i>Anasa andresii</i> , an enemy of cucurbits, Jones.....	55
<i>Triphleps insidiosus</i> as the probable transmitter of corn-car rot, Hyslop.....	55
Some unpublished notes on <i>Pemphigus betæ</i> , Maxson.....	55
Dispersion of scale insects by the wind, Quayle.....	55
Reducing the cost of commercial spraying, Woglum.....	55
The white-marked tussock moth ( <i>Heemerocampa leucostigma</i> ), Yingling.....	55
The New Mexico range caterpillar and its control, Wildermuth and Caffrey.... 55	55
The small pink corn worm ( <i>Batrachedra rileyi</i> ) in Mississippi, Harned.....	56
Control of the variegated cutworm in Ventura County, California, Bensel.... 56	56
A coccid-feeding moth ( <i>Blastobasis</i> ) <i>Holocera iceryælla</i> , Essig.....	56
Additional notes on use of dust sprays against corn-car worm, McColloch.... 56	56
<i>Bucculatrix thurbericella</i> , a pest of cotton in the Imperial Valley, McGregor.... 56	56
Economic Syrphidæ in California, Davidson.....	56
Dispersion of <i>Musca domestica</i> under city conditions in Montana, Parker.....	56
Some observations on the breeding habits of the common house fly, Evans.... 57	57
Sarcophagidæ of New England: Genus <i>Sarcophaga</i> , Parker.....	57
Notes on <i>Pegomya hyoscyami</i> , Cory.....	57
The columbine leaf miner, Cory.....	57
Injury to peanuts by the twelve-spotted cucumber beetle, Fink.....	57
Lachnosterna larvæ as a possible food supply, Howard.....	57
Note on predacious habits of <i>Dineutes</i> toward <i>Anopheles</i> larvæ, Derivaux.... 57	57
The eggplant tortoise beetle, Jones.....	57
The fruit-tree leaf Syneta, spraying data, and biological notes, Mozzette.... 58	58
Reflex "bleeding" of the coccinellid beetle, <i>Epilachna borealis</i> , McIndoo.... 58	58
Notes on the habits of a dangerous genus of weevils, Pierce.....	58
<i>Sporotrichum globuliferum</i> , a natural enemy of the alfalfa weevil, Rockwood... 58	58
Report from the division of bees for 1915, Sladen et al.....	58
Detection of arsenic in bees, Holland.....	59
Professor Gossard's theory on fire blight transmission, Phillips.....	59
The chrysanthemum gall fly, <i>Diarthronomyia hypogæa</i> , Essig.....	59
A new species of <i>Isosoma</i> attacking wheat in Utah, Doane.....	59
Descriptions of and observations on some chalcidoid Hymenoptera, Girault... 60	60
An egg parasite of the army worm ( <i>Heliothila unipuncta</i> ), Flint.....	60
Notes on <i>Rhogas terminalis</i> , Pennington.....	60
Breeding fruit fly parasites in the Hawaiian Islands, Bridwell.....	60
Municipal control of the Argentine ant, De Ong.....	60

## FOODS—HUMAN NUTRITION.

	Page.
The vegetarian diet in the light of our present knowledge, McCollum et al.....	60
The distribution in plants of the fat-soluble A, McCollum et al.....	61
Relation of fat-soluble A and water-soluble B to milk, McCollum et al.....	62
Studies on experimental scurvy in guinea pigs, Jackson and Moore.....	62
The salicylic acid reaction of beans, Brill.....	63
Canned sea urchin, Shutt.....	63
1,001 tests of foods, beverages, and toilet accessories, Wiley and Pierce.....	63
[South Dakota food and drug law].....	63
Report of the dairy and food commissioner for the year 1914, Purcell.....	63
Annual report of the dairy and food commissioner of Virginia, Purcell.....	63
Storage, handling, and sale of food in Philadelphia, Lit.....	63
Food inspection service in Philadelphia.....	64
A photographic method for measuring the surface area of the body, Benedict..	64
Relationship between body surface and heat production, Benedict.....	64
Effects of exposure to cold on infection of respiratory tract, Miller and Noble..	64

## ANIMAL PRODUCTION.

The relative value of field roots, Shutt.....	65
Fodders and feeding stuffs, Shutt.....	65
Beef cattle, Archibald et al.....	65
Sheep, Archibald et al.....	66
Swine, Archibald et al.....	68
Horses, Archibald et al.....	69
Mule production in the South and methods of management, Gayle and Lloyd..	70
Report from poultry division for year ended March 31, 1915, Elford et al.....	70
Studies on physiology of reproduction in domestic fowl, XV, Pearl and Curtis..	73
The Shoup oat sprouter, Shoup.....	75

## DAIRY FARMING—DAIRYING.

Dairy cattle, Archibald et al.....	75
Cow records pay.....	77
Studies on the creaming ability of milk, Hammer.....	77
The creamery and testers' license law. Report for 1916, Hunziker and Ogle..	78
Effects of binders on melting and hardness of ice cream, Holdaway and Reynolds	78

## VETERINARY MEDICINE.

Report of the commissioner of animal industry for 1914, Walker.....	79
Report of the commissioner of animal industry for 1915, Howard.....	79
[Report of the] department of veterinary science and bacteriology, Mack.....	79
A study of soy bean hay, Whittier.....	79
Analyses and nitrogen distribution of a number of antisera, Banzhaf et al.....	80
The intrapalpebral mallein test, Goodall.....	80
Cell proliferative changes in diagnosis of rabies, Hardenbergh and Underhill..	80
Experimental epidemiology in tuberculosis, Distaso.....	81
Producing antigen for complement fixation in tuberculosis, Miller and Zinseer..	81
Fate of mammalian tuberculosis bacillus in chickens, Van Es and Schalk.....	81
Bovine tuberculosis, Haring.....	81
Temperature records in healthy and tuberculous bovines, Jones and Woodhead	82
The diastase in the saliva of the ox, Palmer.....	82
A simple method of obtaining serum for the agglutination test, Bevan.....	82
Immature fetus as standard for measuring prevalence of abortion, Williams....	82
The outlook for the control of cattle abortion, Williams.....	82
Lymphangitis in cattle caused by an acid-alcoholic-fast organism, Traum.....	82
The liver fluke disease, its treatment and control, Marek.....	83
Investigation into "louping-ill" or "trembling," M'Gowan.....	83
Additional notes on pathological lesions of pigs fed rice meal, Hadwen.....	83
Occurrence of petechial hemorrhages in hog cholera, Hoskins.....	83
Observations on 2,800 pigs inoculated with hog-cholera virus, Hoskins.....	84
The attenuation of hog-cholera virus, Healy and Gott.....	84
The pathology and epidemiology of swine fever, M'Gowan.....	85
Paralysis of pigs, Wehrbein.....	85
Parasites of hogs, Stouder and Simonsen.....	85
Shipping fever of horses, Mohler.....	85

A new disease in ducklings, Elford.....	85
The transmission of filaria by Chrysops, Kleine.....	86
New host for <i>Fasciola magna</i> and distribution of <i>F. hepatica</i> in Canada, Hadwen.....	86
Occurrence of <i>Diocotylome renale</i> in United States and Canada, Riley.....	86

## RURAL ENGINEERING.

Rural engineering and the war of 1914-1916, Ringelmann.....	86
Surface water supply of south Atlantic and eastern Gulf of Mexico basins, 1914.....	86
Surface water supply of Snake River basin, 1914.....	86
Well waters from farm homesteads, Shutt.....	86
Flow of water into wells: Approximate theory, Werenskiold.....	87
Experience with wood pipes in New Hampshire, Dudley.....	87
Influence of the algæ in water purification, Diénert and Gizolme.....	87
Waterworks handbook, compiled by Flinn, Weston, and Bogert.....	87
Methods and cost of making a snow survey for irrigation system, Cummings.....	87
Subirrigation, Spencer and Berry.....	88
Cost of pumping for irrigation, Waller.....	88
Cost of structures of the second unit of the Dodson north canal, Bechtel.....	89
Irrigation of Thanh-Hoa, Peytavin.....	89
Irrigation practice in growing small fruits in California, Hutchins.....	89
Utilization of small waterfalls for drainage and irrigation, Rostovtsev.....	89
Tile drainage, Leidigh and Gee.....	89
Ditching and digging pole holes with dynamite, Knight.....	89
Land clearing, Moore.....	89
Major results of stump removal investigation, Livingston.....	89
State highway mileage and expenditures for the calendar year 1915.....	90
Proceedings of thirteenth convention of American Road Builders' Association.....	90
Unit stresses for timber: Manufacturers' table.....	91
New dairy cattle barns, Archibald.....	91
The homemade stave silo, Price.....	91
Pit silos and how to make them, Paschall.....	91

## RURAL ECONOMICS.

Can the farmer realize higher prices for his crops by holding them? Pope.....	91
Marketing farm produce by parcel post and express, Hibbard and Hobson.....	91
Values of grain and similar products based on dry-matter content, Boerner.....	92
Monthly crop report.....	92
Statistical tables relating to wheat, Shirras.....	92
Farmers' cooperative corporations, Cance and Jefferson.....	92
Eugenics and agriculture, Cook.....	92
Community centers, Phelan.....	92
The church and country life, edited by Vogt.....	92
Country life questions and answers.....	93
Bibliography on country life, the farm, and the small town.....	93
Rural progress in Missouri, Nelson.....	93
Statistical report of the California State Board of Agriculture, 1915.....	93
[Agricultural resources of Rhode Island].....	93
The agricultural situation in the Philippine Islands, Edwards.....	93
The farm prize competitions, Orwin.....	93
Agricultural statistics of Galicia and Bukowina, 1914.....	93
[Agriculture in the Commonwealth of Australia], Knibbs.....	93

## AGRICULTURAL EDUCATION.

A state system of agricultural education, Butterfield.....	93
County training schools in Alabama, Sibley.....	94
Decline and fall of a state system of boys' and girls' clubs, Main.....	94
School gardening a fundamental factor in education, Harvey.....	94
Report on the work of the Direction of Agriculture for 1913.....	95
Production of alfalfa east of the ninety-fifth meridian, Westover and Hendrick.....	95
Illustrated lecture on corn production, Hartley and Hendrick.....	95
The North Carolina corn bulletin, Balcomb.....	95
Illustrated lecture on orchard management, Connolly and Glasson.....	95
Illustrated lecture on how to make good farm butter, McClain.....	95
Dairying project, Norcross and Scott.....	95

	Page.
Illustrated lecture on cattle-tick eradication.....	95
Manual training for the rural schools, Roehl.....	96
Correspondence courses for teachers. Course III, Home economics.....	96
Home economics: Its opportunities and obligations, Bevier.....	96
Interdependence of forest conservation and forestry education, Toumey .....	96

## MISCELLANEOUS.

Thirty-ninth Annual Report of Connecticut State Station, 1915.....	97
Annual Report of Nevada Station, 1915.....	97
Report of the Canada Experimental Farms, 1915.....	97
Monthly Bulletin of the Ohio Experiment Station.....	97
Monthly bulletin of the Western Washington Substation.....	97
A handy field and laboratory binocular magnifier, Woglum.....	97

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	Page.	<i>U. S. Department of Agriculture.</i>	Page.
Arkansas Station:		Jour. Agr. Research, vol. 6, No. 25,	
Bul. 123, May, 1916.....	39	Sept. 18, 1916.....	12, 73
California Station:		Bul. 374, The Intrinsic Values of

# EXPERIMENT STATION RECORD.

VOL. 36.

JANUARY, 1917.

No. 1.

---

The annual meeting of the American Association for the Advancement of Science is one of the great scientific events of the year. It is a vast clearinghouse for ideas and results in science, and for the testing and molding of views. It presents the largest forum in this country for healthy, tempered but searching criticism in science, without which science becomes self-complacent, lax, and unexact in its requirements.

Beyond this, such a meeting of men associated with the various branches of science has a remarkably broadening influence. One gets new insight, suggestion, and inspiration from such a contact of minds, such a presentation of evidence, such a weighing and testing of results and of views. The individual finds anew that his branch of science or his specialty has relations beyond the narrow limits in which he has been considering it, and that there is not only an interest in following this broader relation, but a danger unless he does that he may specialize too closely in his thinking and view his subject out of focus.

Hence it seems worth while for the man of science to foregather from time to time with his colleagues in the annual convocation, worth the time and worth the money outlay. This is not so much to listen to papers which might be read or to present a report which might be published, but to keep his mind from narrowing, to maintain a contact with science which is well nigh impossible otherwise, and an association which contributes so much to the zeal and the satisfaction of a scientific career. It brings him definitely into membership in that great fraternity of workers in the broad field of science—some for its own sake, some for its relations to human welfare, all having the common purpose to advance knowledge and understanding. It was the belief in such advantages that led thousands of men and women to journey long distances, many from the South and the West, to attend the New York meeting.

The relation to agriculture of considerable parts of the programs of various sections and affiliated societies seems increasingly greater with each succeeding meeting. Perhaps it is because our interest is broadening. Perhaps it is because the investigation in agriculture

is leading more and more deeply into the realm of the sciences. And undoubtedly it is because interest in these problems is becoming more widespread, for the problems of agriculture are now attracting the attention of very many men and women identified with nonagricultural institutions. The biological chemists, the various botanical organizations, the entomologists, the zoologists, the geneticists, the ecologists, all had papers of immediate import to agricultural investigation. Indeed, there were so many of these contributions and discussions that the difficulty was to hear more than a small part and to make a selection.

The Section of Agriculture confined its program to a single session, in order to avoid conflict with the programs of other agricultural organizations meeting during the week. The session was presided over by Dr. W. H. Jordan, of the New York State Experiment Station. Unfortunately the retiring vice president, Dean E. Davenport of Illinois, was unable to reach the meeting owing to delayed railroad transportation, and his address accordingly had to be omitted. The program consisted of a symposium on The Adjustment of Science to Practice in Agriculture, participated in by Dr. H. J. Wheeler of Boston, Dr. J. G. Lipman of New Jersey, Dr. G. F. Warren of Cornell University, and Director B. Youngblood of the Texas Station.

Taken as a whole, this discussion was a frank acknowledgment of the present limitations of our agricultural knowledge, especially the full understanding of it, and some of the difficulties in its application in successful farming. It was a somewhat critical analysis of experimental methods, and it sounded a caution against premature generalization from laboratory results to the farm. The more we study and learn, the clearer it becomes that science may not always be applied equally and uniformly under existing local, economic, and other conditions, and that safe teaching requires consideration of many things. The keynote of the discussion was the conduct of broader and more searching inquiries and greater caution in their interpretation. As Dr. Jordan stated, the stations have been and are still putting too much time on mere variables that have no broad significance, and too little time on broad fundamentals. He called attention to the fallacy and unwisdom of attempting to state results in terms of dollars and cents, since these have no real permanent or scientific significance.

In considering some factors lying between scientific results and the farm, Dr. Wheeler grouped these factors under the heads of political, economic, and technical. Holding that agriculture needs to be stimulated by political action, so as to provide not only favorable but

stable conditions for the industry, he maintained that a depressed condition of agriculture is generally unfavorable to the application of science. The encouragement of private ownership of land, adjustment of the size of the farm to the farmer's capacity, and the establishment of industries like beet sugar and potato drying, which distribute and give employment to the farm laborer, all make for general conditions under which science can be effectively and profitably applied. Education is another great factor in making science applicable. Illustrations were cited from Germany to show how such favorable conditions have been a means for developing agriculture upon a high plane and placing it upon a broad scientific basis.

On the technical side emphasis was laid on the importance of the true interpretation of science in practice. This has not always followed from investigation, as was shown by numerous illustrations. It results from a broad generalization from laboratory experiments under artificial conditions to terms of general practice. Attention was called to some of the factors which may upset the laboratory results and conclusions when they come to be applied, such as soil type, climatic conditions, the inducing of disease, etc. The present receptive condition of the farmers and their readiness to adopt suggestions make it doubly important that our teaching should be sound.

Considering the subject of the limitations of science to progress in agriculture, Dr. Lipman, while recognizing that in a strict sense there are no limitations in science as long as we keep within natural laws, pointed to certain human limitations in the development of science and in its successful application in practice. He advocated with much force the adequate preparation of men for research in agriculture as essential if the present limitation is to be removed. Lack of vision was cited as a most frequent deficiency; the outlook needs to be broader as our problems become more difficult and complex.

The greatest present limitation of science in agriculture was considered to be its effective application. The man power is the real measure of efficiency in production, rather than the acre yield, and the increase in this efficiency rests upon the spread of education. To raise the scale of production there must be a higher level of education among the mass of farmers, to bring up those below the average and to raise the average up to the better ones. Economic conditions constitute another type of limitation in determining the extent to which scientific knowledge can be applied in practice, as do also lack of working capital, location remote from market or from transportation facilities, and the lack of cooperation among producers. The latter was regarded as an especially serious limitation, because single-handed the American farmer is frequently not able to fully

utilize the findings of science as would be possible in applying these to broader areas.

The relation of economic factors was further discussed by Dr. Warren, who held that in applying science to industry no method is scientific which fails to count the cost. The farmer must take account of this before he is warranted in making radical changes, but it is not always done in making practical deductions from scientific findings. He contended that agriculture is not the inefficient art that it has often been represented to be, and that while it can be improved the chances for improvement are less than in most other industries. In a region of settled farming, radical changes in the type of farming are justified only after careful study of all the factors involved.

Transportation affects the application of science, for it should in large measure determine the type of farming. Sugar can be shipped long distances; hence New York can not afford to grow its own sugar, although the climate and soil are favorable and there was a vigorous effort to establish the industry. Risk was cited as an important factor in tending to hold down the intensity of farm practice. Whenever one factor of cost is changed it is probable that others will be changed also. For example, with better cows the cost is increased and the net advantage may be smaller than is indicated by the difference between feed cost and value of product. Other examples of diminishing returns were cited to show the dangers in making practical application of scientific results without weighing carefully all the economic and practical considerations.

The effect of regional conditions as determining the type of agricultural inquiry was considered by Professor Youngblood, who used for illustration the State of Texas. The variation within the State in rainfall is from fifty-five inches in the east to about eight inches in the extreme west, in elevation from sea level to approximately five thousand feet, in topography from flat to rough, in temperature from semitropical to strictly temperate, and the soils of different localities are derived from various phases of at least ten geological periods. Beyond these physical differences the general character of agriculture, the distance from market, and the intellectual status of the people all have to be taken into account in adjusting the agricultural inquiry to the needs. Without omitting the fundamentals, account must be taken of the practically useful and applicable information in laying out the station's work. Since the object of the station is service, both present and future, "we should endeavor to educate the people up to the point of appreciating all investigation, however simple or technical, by assisting them to appreciate the possible value of the results which may ultimately be obtained."

The speaker thus made clear in how large a degree regional conditions affect the type and the grade of experimental work. His plan is to develop at the central station a strong scientific basis on which to rest the experiments dealing with special local problems. He expressed his conviction that even under the new and often transitional conditions in his State, technical studies may be of the greatest practical value and may be made popular with the people.

This series of papers represented much thoughtful study. It is difficult to give an adequate idea of them in so brief a review. They are worthy of publication in full, for they put into succinct, cogent form a series of considerations which are fundamental to safe progress at the present time.

The old questions as to what research is, how investigation should be organized, how men should be trained for it, how coordination or correlation can be brought about, came to the surface again, especially in the meetings of the Society for Horticultural Science and the Society of American Foresters. These matters can not be too fully discussed. We are not at the end in our understanding of them or in providing measures for their accomplishment.

The Society for Horticultural Science last year appointed a committee on research and experimentation, which reported at the New York meeting through Dr. L. H. Bailey, its chairman. The report was divided into three parts, namely, a definition of terms, by Dr. W. L. Howard, of California; the laying out of an experiment, by Dr. H. J. Webber, of the California Citrus Experiment Station; and the training of the investigator, by the chairman.

Dr. Howard's paper gave an admirably clear and intelligent view of the different classes of experimental effort. These are characterized by their ultimate purpose quite as much as by their method. In explaining his meaning he compared the discoveries of the Indians, which meant little to them beyond supplying their own immediate wants, to those of the early explorers of this country, to whom the finding or exploring of a river was a means to an end, who "sought outlets, gateways, to their own or other countries, which might be an aid to settlement and commerce."

Again he explained that a man may take a walk without the intention of going anywhere in particular and get benefit from it, or he may set out for some definite place or to search for some rare or elusive object. The first instance was likened to a simple experiment, while the latter was described as more in the nature of research. "A simple experiment may be performed and actually answer the question and may stop there. Also, in answering the question another question may be raised which may require another experiment or

test. This in turn may be similarly tested and decided, when others may arise, and so on; but all such tests remain in the category of experiments. During the course of the experiments, however, the experimenter may come to the conclusion that there is some hidden reason at the bottom of all his tests which may explain why he has been getting certain results—something that will clear up the whole situation.”

Applying this to pollination studies, Dr. Howard traced the imaginary progress of successive tests and experiments showing that certain varieties are self-sterile and that others are good pollinizers for these varieties, and that certain varieties are intersterile while a certain few are safe pollinators for many—all facts of practical value but giving no clue to why a certain variety is fertile or self-sterile. This may lead the experimenter to theorize as to the possible reason and the series of experiments to approach the stage of investigation. “When a definite program has been mapped out which has for its object the finding out of the cause or causes which underlie self-fertility or self-sterility in general, or for the particular fruit in question, with a logically arranged set of experiments for pursuing the inquiry, the problem develops at once into a genuine piece of research.”

This explanation characterizes the different grades of inquiry with unusual clearness. It explains at once the quality and method of the inquiry when it reaches the research stage, and it makes it clear why an experimenter can not embark upon a piece of research until he has a purpose which lies beyond the accumulation of facts and a theory or hypothesis which guides him in elaborating a plan. It also makes clear the importance of the project outline, and the reasonableness of the requirement. For clearly the title alone does not disclose the nature of the effort; it only tells what the contemplated work is about and what field it lies in. A statement of the object and the plan of procedure is the only basis for a fair and intelligent judgment of the undertaking, for it enables a determination of whether the effort is to consist in a series of tests, the gathering of unrelated facts, the making of observations on phenomena, or whether it contemplates a study of phenomena in their relations to one another. Hence the project outline is an administrative necessity. It furnishes evidence of deliberation and forethought. It is not an attempt to anticipate results but a deliberate effort to devise a promising means of getting them for a specific purpose. And it is not fixed or stereotyped; the project soon becomes sterile unless the plan grows with the progress of the study.

As Dr. Howard well stated: “Experiments are necessary steps in carrying on research work, but it is also clear that research is much

deeper than experimentation. Experimental tests of various kinds are necessary and perfectly justifiable, and always will be, and more experimental work should be encouraged, but experiments as such should not be confused in their meaning and objects with the scope and ultimate aims of research."

As Dr. Bailey explained in commenting on this paper, the characterization of research lies in its intent. Facts alone do not make research—they make tables. Dollars and cents are not the terms of research; its interpretation lies in its own language. Application is not necessarily a part of research; the object is to discover and express the truth. It does not depend on the size of the undertaking or the money spent upon it. Because it is an attitude and a spirit it can not be definitely defined. But Dr. Howard's excellent paper will help much in defining its qualities and distinctions.

In discussing the method of laying out an experiment, Dr. Webber divided the investigations of an experiment station into two classes, individual and institutional problems, *i. e.*, (1) problems of limited nature which can best be handled by an individual investigator, and (2) those which because of their breadth and time requirement concern the whole institution and involve several departments. The leader of an individual problem, it was urged, should be given the greatest possible scope of freedom in planning and executing his work; his success will depend upon his individual initiative and originality.

The case with the institutional problem is different. Here many persons are concerned and there is need of harmonious action. As an illustration of this class, a fertilizer experiment with orchard fruits was cited, "if it is correctly planned and manned," because it is expensive in time and funds and concerns a number of departments of the station. Regarding the essentials of such a study, Dr. Webber said: "A fertilizer, irrigation, or cultivation experiment, if it is to have its highest value and yield the greatest number of useful lessons, must be studied by chemists, soil physicists, plant physiologists, soil bacteriologists, pathologists, and crop experts. Experiments that cost so much should be used to the maximum extent. Very few experiments of this kind now under way are being so studied. This, I believe, is in large measure due to a failure to recognize what should be individual and what institutional experiments."

This is an important statement and develops a point often overlooked. Many of our field experiments continue to be studied from too narrow a point of view because they are conducted as individual studies. Advantage is not taken of the opportunity afforded to study

other phenomena and relationships beyond those the author of the experiment has in mind. Hence the most is not made of these expensive undertakings, important by-products are overlooked, and at the same time the experiments themselves are weakened because they do not include a complete study of the exact conditions and the changes brought about, both in the environment and in the plant response.

Dr. Webber's ideas on the method of organizing institutional experiments are interesting because the subject is so fundamental in accomplishing these broader aims. He considered two plans: (1) Through a committee comprised of men representing all the branches of science concerned in the experiment, and (2) by a strong team captain. The committee plan is more common but its danger "lies in the possibility that the plan finally adopted may be a result of compromise that will be a hodgepodge, that after all may be emasculated of its most vital points. The most valuable series of experiments in the history of science are usually those planned to solve certain points."

Here again a vital matter is touched upon, for it frequently happens, as indicated, that in such composite investigations each participant works out the part of the problem he is particularly interested in from his own point of view, and the main question which the investigation set out to solve is advanced but little because there is no common aim, no unity, no one to keep the effort focused on a definite point and to marshal the data to bear upon it. Such a plan is a distinct weakness in the study of "institutional" problems. The direction of such problems is an institutional matter. These considerations led Dr. Webber to favor the individual leader—"a strong, virile investigator with originality, vision, and training of the right kind," who would be charged with the sole responsibility of planning the experiments, getting all the help possible from the various departments, and would center the effort on the solution of certain fundamental questions, giving it definiteness and freedom from compromise.

In commenting on this paper Dr. Bailey, while fully recognizing the importance of individuality in research, pointed to the danger of such a division of institutional problems as to result in diffusion of responsibility, inequality of enterprise, and lack of coordination. In investigation of institutional problems, he held for such coordination of all parts as will give it responsibility, cohesion, and system.

Speaking of the training of the investigator, Dr. Bailey held that the research man should be a student in all that the name implies. The investigator in horticulture should have a grounding in chemistry, physics, and physiology, for the grasp they give on methods and

approach. And he should have training in systematic botany, not alone for its knowledge of plants but for its key system, for the drill in comparing things that are actually comparable. His training should also give him a contemplative, reflective habit of thought; and he should always continue to be a student. Unless he continues to acquire much of his preparation as he goes, his research spirit has got its growth. The investigator must prepare himself for each separate piece of work.

In addition to this training in the sciences, emphasis was laid on the need for much study of English, to give familiarity with words and terms in order to make sharp discriminations and comparisons, and to enable clear expression of thought and deduction. This is an all too frequent lack at present. Science is exact, in expression as well as in essence. No worker has a right to be understood except in the terms of his own language. Good training in logic was also advocated, in the weighing of evidence, because ability in that line is one of the prime essentials of the investigator.

In conclusion, Dr. Bailey suggested a small standing committee on research, one member of which might preferably be chosen from outside the field of horticultural science, to whom questions might be referred for judgment and suggestion, rather than for censorship or approval. This seems a good idea, which might perhaps be extended, as it has been in other organizations, to include the suggestion by the committee of profitable lines of work, the organization of cooperative undertakings, or provision for some measure of coordination of experiments in horticulture. This might lead to attacking common problems in a more harmonious way or on a plan which would prevent unnecessary duplication, complex subjects being divided into different phases to be carried on by individuals or groups. The society did not go that far, but the suggestion was made for an indexing and publication of the lines of investigation in progress in horticulture, possibly in the proceedings of the society, which met with approval.

A similar need for information as to what is going on was voiced in a meeting of the Society of American Foresters. This meeting developed much interest in forest investigation, and brought out not only the need of professional foresters and teachers for investigation as a basis in their work, but the readiness for it by industrial concerns and large lumber producers.

The experimental and research work in progress in the Forest Service was described in an interesting paper by Mr. E. H. Clapp of that Service, who explained the extent to which wood producers are found to be lacking in knowledge of the real fundamentals of their business. Practical men are now realizing the lack of depend-

able information and are ready to make use of the teachings of investigation. The special demand at the present time is in the field of forest products, but to those engaged in investigation the field now appears much larger than it did at the beginning, and they realize that demands will be upon them long before they can be ready to meet them.

While the Forest Service is the largest center for investigation, experimental work is going on incidentally in many other places, but, as was pointed out, there is no cooperation or correlation, and no means of knowing what others are doing. The advantage of the periodical publication of projects was emphasized, and the correlation of the forest investigations of the country was advocated. Such a correlation, it was explained, would be wholly voluntary and brought about by suggestion; but some provision for it was deemed especially desirable in these early stages of investigation, before the plans became so crystallized and fixed that changes can not well be made.

The proposal for coordination brought forward some doubt as to its desirability or feasibility, and an expression of the difficulty of cooperation or coordination in research similar to that advanced when cooperation in agricultural investigation has been under consideration. It is noteworthy in these discussions, however, that the term "research" is used in a generic sense to include the various grades of experimental inquiry, while those who have advocated a larger measure of coordination and cooperation have not applied the argument to research in its more strict sense.

There seems to be quite widespread objection to any proposal which aims to bring experimenters together or harmonize the plans for their experiments. Is it because our investigation in agriculture and forestry is so much younger than that in the sciences, and lacks background to give confidence in the attempt of men to cooperate with one another? Or is it purely academic, in the belief that even the simpler forms of experimentation should not be related for fear they will be stereotyped or possibly centralized, but should be left wholly to the independent worker? Suggestion has been a powerful influence with the rank and file of experimenters in the past. Very much of our experimental work in agriculture has followed the lead of the few, but not in a manner to contribute in the largest measure to confirmation or to progress.

The same feeling does not seem to prevail in the older sciences; the astronomers have long worked under a common agreement which rests upon a division of the field, the chemists have cooperated in the study and development of methods, the botanists have encouraged the development of special lines by groups of workers, and the geographers have had an effective international agreement relative to map

making. Recently the ecologists have embarked upon a large program of cooperation on climatology in relation to plants and animals.

This latter enterprise has been developed in the Ecological Society of America, established a year ago, through a climatological committee. Cooperative studies in special lines are being participated in by a considerable number of workers. One subcommittee has to do with soil temperature as an environmental factor of special interest to entomologists and pathologists, to foresters, to crop specialists, and a wide range of workers. This subcommittee has organized soil temperature studies, to be carried on cooperatively in accordance with a relatively simple plan, and has met with ready response from investigators, who have been willing to put funds into the work and adhere to a plan which would make their results comparable. The undertaking recognizes that there must be leadership and plan, with provision for assembling the data, but it also recognizes that the plan should be a simple one, should not attack too large a question at any one time, and should allow the maximum individual liberty consistent with comparative data. The effort is especially interesting because of the faith it shows and the response there has been to it.

Cooperation or coordination can not be forced and it can not thrive unless there is a spirit and attitude on the part of the individuals and the institutions, which recognizes the limitations of the individual and the fact that in many things science and the common good can best be promoted by a closer union of effort.

At present there seems to be widespread interest in some means of giving fairly prompt publicity to the lines of investigation in progress, in order that investigators may know what experiments and researches are being conducted in the lines they are especially interested in, and where this work is going on. This is an encouraging sign. It offers a means of approach. The provision of information regarding lines of work and specific undertakings would furnish a means by which investigators who desired could draw closer together, and by which unnecessary duplication could be avoided and the results of separate experiments made to supplement one another more definitely.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Studies in the physical chemistry of essential oils (*Proc. Roy. Soc. Victoria, n. ser.*, 27 (1915), No. 2, pp. 149-163, figs. 2).—Two papers are presented.

I. *The physical properties of mixtures of two terpene substances in relation to those of the constituents*, R. B. DREW and E. I. ROSENBLUM (pp. 149-155).—The results of the study show that simple mixtures of two terpene compounds follow the "mixture law" quite closely. Any divergencies are eliminated by the use of certain formulas. For such mixtures the proportions of the constituents can be calculated from the properties of the mixture, provided none of the constituents are unstable. In such cases the deductions are unreliable.

II. *The physical constants of some terpenes and oxygenated derivatives thereof, and their variation with temperature*, E. I. ROSENBLUM (pp. 155-163).—The influence of temperature change on the density, refractive index, and rotation of a number of terpenes and allied substances has been investigated, and the results are submitted in tabular and graphical form.

Some numerical relations among the rotatory powers of the compound sugars, C. S. HUDSON (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 8, pp. 1566-1575).

The isomeric alpha and beta hexacetates of  $\alpha$ -glucoheptose, C. S. HUDSON and E. YANOVSKY (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 8, pp. 1575-1577).

$\alpha$ -Crotonic acid, a soil constituent, E. H. WALTERS and L. E. WISE (*U. S. Dept. Agr., Jour. Agr. Research*, 6 (1916), No. 25, pp. 1043-1046, pl. 1).—The authors have isolated  $\alpha$ -crotonic acid from a Susquehanna fine sandy loam found in a field near Marshall, Tex. The soil was of such a nature as to present optimum conditions for the formation and accumulation of organic acids.

The acid was isolated from an alkaline extract obtained by treating the soil with an aqueous 2 per cent sodium hydroxid solution for 24 hours at room temperature. The extract thus obtained was slightly acidified with sulphuric acid and filtered. The acid filtrate was extracted with ether, the ether extract evaporated to about 200 cc., and aldehydes and similar substances removed by treatment with sodium bisulphite. The bisulphite solution was extracted several times with fresh ether, the ether extracts combined, and slowly evaporated to a brown sirup in a small crystallizing dish. The dish was then covered with a watch glass containing ether and maintained at a low temperature on a steam bath. A white crystalline solid gradually sublimed on the watch glass. The sublimed substance was dried between filter paper, recrystallized from petroleum ether, further purified by subliming several times at a low temperature, and finally dried over anhydrous calcium chlorid. Physical and chemical tests identified the material as  $\alpha$ -crotonic acid.

It is suggested that the acid is possibly formed in soils "during the destruction of cellulose, from  $\beta$ -hydroxy acids of the aliphatic series, or by the hydrolysis of allyl cyanid, which is found in the essential oils from certain plants."

Biochemical changes in cotton seed in storage, J. B. RATHER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 604-607, figs. 2).—This material has been essentially noted from another source (E. S. R., 35, p. 412).

Experiments upon the amylase of *Aspergillus oryzae*, H. C. SHERMAN and A. P. TANBERG (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 8, pp. 1638-1645).—From the study reported, the object of which was to purify the amylase as far as practicable and to compare its nature and properties with those of the pancreatic and malt amylases, it was found that the amylase of *A. oryzae* exerts its maximum activity in a very slightly acid medium. Acid phosphate accelerates the action, while alkaline phosphate retards it. "Addition of neutral electrolytes, such as sodium and potassium chlorids, to commercial taka-diastrase has no measurable effect upon the saccharogenic power, but does increase the amyloclastic action."

The best preparations were obtained by extracting with water, precipitating with ammonium sulphate, dialyzing, and finally precipitating fractionally with alcohol. Such preparations are about thirty times as active as the commercial material from which they are prepared, but are not so active as the purified pancreatic amylase.

"The purified material resembled the preparations of pancreatic and malt amylases in most of its chemical properties. It gave typical protein reactions when submitted to the Millon, xanthoproteic, tryptophan, and biuret tests. Heated in water solution it underwent coagulation, and the coagulum and filtrate both showed the biuret reaction, the color being considerably pinker in the case of the filtrate than with either the coagulum or the original material. That its nitrogen content was lower than that of the best preparations of pancreatic and malt amylases may be due either to a difference in the chemical nature of the enzyme itself or to the presence of other substances which the methods of purification thus far developed do not wholly remove."

Researches on the enzymes of the blood in the albumin and globulin fractions of the serum, G. SATTÀ (*Arch. Ital. Biol.*, 64 (1915), No. 1, pp. 118-122).—It is shown, by separating the blood serum into its albumin and globulin fractions, that the tributyrinase, amylase, and glycytyrosinase of the blood serum exist exclusively in the albumin fraction.

A nonspattering wash bottle, F. C. CLAPP (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 8, pp. 1502, 1503, fig. 1).—The author, at the Minnesota Experiment Station, describes a wash bottle so constructed as to obviate spattering at the tip of the nozzle. The principle of raising the water table of the wash bottle slightly above the level of the tip of the nozzle has been adopted in its construction. "Back action" is thus avoided and the nozzle tube is kept permanently full of water.

Researches on quinazolins.—XXXIII, A new and sensitive indicator for acidimetry and alkalimetry, and for the determination of hydrogen-ion concentrations between the limits of 6 and 8 on the Sørensen scale, M. T. BOGERT and G. SCATCHARD (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 8, pp. 1606-1615).—The authors describe the preparation and use of a dinitrobenzoylene urea, the monosodium salt of which is a very sensitive indicator for hydrogen-ion concentrations between the limits of 6 and 8 on the Sørensen scale, changing from colorless to greenish yellow. It resembles *p*-nitrophenol more closely than any of the other well-known indicators. The chief disadvantage of its use is its yellow color, which renders it unsuitable for work by artificial light. The indicator is but slightly affected by neutral salts and proteins, and not at all by chloroform or toluene. Its color fades very slightly in about a week, but is unaffected by nitrous acid. It can be used in either cold or boiling solutions. A sharp end point is obtained with ammonium hydroxid and hydrochloric acid, but it is unsuitable for use in titrating carbonates.

The opinion is expressed that in the preparation of neutral ammonium citrate for fertilizer or soil analysis it should prove superior to rosolic acid.

Kjeldahl modification for determination of nitrogen in nitro substitution compounds, W. C. COPE (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 592, 593).—The following procedure is described:

About 0.5 gm. of the nitro substitution compound is accurately weighed and placed in a 500-cc. long-necked Kjeldahl digestion flask. Thirty cc. of sulphuric acid containing 2 gm. of salicylic acid is then added, and the nitro compound dissolved by rotating the flask or heating over a steam bath if necessary. After cooling, 2 gm. of zinc dust in small proportions at a time is added, the flask being continually rotated and cooled to prevent heating above room temperature. After all the zinc has been added the flask is rotated at 10 or 15 minute intervals for about 1.5 to 2 hours, and then allowed to stand overnight at room temperature. The flask is then gently heated over a small flame until the evolution of fumes has ceased, brought to boiling, and the boiling continued for from 1.5 to 2 hours, slightly cooled, 1 gm. of yellow<sup>a</sup> mercuric oxid added, and boiled for 1.5 hours longer. After cooling, 7.5 gm. potassium sulphate and 10 cc. more of sulphuric acid are added and the mixture again boiled for 1.5 to 2 hours. If the solution is clear and practically colorless the digestion is complete. If not, 1 gm. more potassium sulphate should be added and boiling continued for some time. The distillation is then carried on and the determination completed as is usual for all modifications of the method.

In order to prevent low results, cooling during the addition of the zinc for reduction and the long standing before heating the acid solution have been found to be absolutely necessary.

Apparatus for Kjeldahl determinations, W. W. RANDALL (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 639, 640, fig. 1).—In the apparatus described the acid fumes are carried off from the digestion flasks through properly fitted calcium chlorid tubes which are connected with a larger tube through which the fumes pass into a large absorption flask. The apparatus is a modification of that described by Sy (*E. S. R.*, 28, p. 311).

Sodium sulphate as a substitute for potassium sulphate in the Gunning modifications for determining nitrogen, W. L. LATHAW (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 586, 587).—On account of the present high price of potassium sulphate an endeavor was made to find a suitable substitute. The results of a series of determinations on materials ranging in nitrogen content from 0.039 to 14.95 per cent, using sodium sulphate in place of potassium sulphate, are reported in tabular form, and clearly indicate that sodium sulphate can be used in place of potassium sulphate for determining nitrogen in a variety of substances.

A modification of McCrudden's method for calcium, for the estimation of calcium and strontium in the presence of phosphoric acid and a small amount of iron, O. B. WINTER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 603, 604).—The author, at the Michigan Experiment Station, has modified McCrudden's method (*E. S. R.*, 23, p. 9) for the determination of calcium and strontium, as follows:

The solution containing the calcium or strontium or both is diluted to about 200 cc., a few drops of alizarin added, and then ammonium hydroxid until the solution is faintly alkaline. Dilute hydrochloric acid is then added to faint acidity. To this solution 10 cc. of half-normal hydrochloric acid and 10 cc. of 2.5 per cent oxalic acid are added and the mixture boiled until the precipitate becomes coarsely granulated. Saturated ammonium oxalate solution is then added, a few drops at a time, with constant stirring, until about twice the amount necessary to precipitate all the calcium and strontium has been added. The solution is cooled, 8 cc. of 20 per cent sodium acetate and about 15 cc. of

95 per cent alcohol added, with constant stirring, and allowed to stand from 4 to 18 hours. The precipitate is then filtered and washed a few times with 1 per cent ammonium oxalate solution, several times with 1 per cent of ammonium oxalate containing 20 per cent by volume of alcohol, and, finally, a few times with water containing 20 per cent by volume of alcohol. The precipitate is burned to the oxid, dissolved in nitric acid, dehydrated, the calcium nitrate separated from the strontium nitrate by means of absolute alcohol and ether, and each element then determined in the usual manner.

Analytical data submitted show the accuracy of the modified procedure.

A table for values of carbon in carbon dioxide, H. LOOMIS (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, p. 637).—A table corrected for aqueous vapor, ranging from 700 to 718 mm. pressure, and from a temperature of 10 to 30° C., is submitted.

A rapid method for the accurate determination of total carbon in soils, R. M. SALTER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 637-639, fig. 1).—A method which has been successfully used at the West Virginia Experiment Station, and which depends on the direct combustion of the soil in a current of oxygen, drying the gases by phosphorus pentoxide, and subsequently absorbing the carbon dioxide in soda-lime, is described in detail. It is an adaptation with modifications of the method described by Fleming<sup>1</sup> for the rapid determination of carbon in iron and steel.

The reducing action of distillates from certain carbohydrates on distillation with steam and from alkaline solution, J. P. ATKINSON (*Collected Studies Bur. Lab. Dept. Health N. Y. City*, 8 (1914-15), pp. 227-229).—In the examination of a sample of water extraordinarily high figures for free ammonia with Nessler's reagent were obtained. On further examination the water was found to contain a reducing sugar. Subsequent experiments with saccharose, lactose, glucose, levulose, maltose, mannose, dextrin, soluble starch, and filter paper showed that these substances may have an influence on the depth of color in ammonia readings, especially in the examination of surface waters which are likely to be contaminated with organic matter.

The rate of ammonia distillation from water, F. W. BRUCKMILLER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 602, 603).—From a study of the rate of ammonia distillation the author concludes that sufficient information upon which to base a judgment as to the pollution of a water can be obtained, in ordinary routine water analysis, by nesslerizing three 50-cc. portions of the distillate for free ammonia, and four 50-cc. portions for albuminoid ammonia.

Melting-point determination of fats and waxes, L. GOLODETZ (*Chem. Ztg.*, 40 (1916), No. 31-32, p. 223, fig. 1).—An apparatus in which a small, closely fitting glass tube about 3.5 cm. long and sealed at one end is placed over the end of the thermometer in melting-point determinations is described.

In making a determination the sample (about 0.2 gm.) is placed in this small tube, gently heated, the thermometer rapidly inserted, and placed in a small vial fitted with a suitable stopper. The mercury column is then closely observed and the point at which the first faint turbidity is noticed taken as the melting point. The advantages claimed for the method are constancy in the results of the determinations; the accuracy of the temperature readings, as the whole apparatus can be conveniently placed on a level with the eye; the facts that only small amounts of material are required, and that these can be used for other determinations if necessary; repeated determinations with the same sample; the rapidity of the procedure; and the simplicity of the apparatus.

<sup>1</sup> Iron Age, 93 (1914), No. 1, pp. 64-66.

The detection of natural and artificial pigments in oleomargarine and butter, L. S. PALMER and W. E. THRUN (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 614-618).—Because of the oleomargarine laws of many States it has been found necessary to detect the presence of carotin (the natural yellow pigment of animal fat) in this product. The authors have shown Cornelison's test (E. S. R., 20, p. 910) to be wrongly quoted by Leach (E. S. R., 29, p. 204). The relation between Martin's test<sup>1</sup> for artificial pigments in fat and Moore's test<sup>2</sup> for carotin added artificially to fat, as given in Leach's Food Inspection and Analysis, is shown to be confused, and the true relation is pointed out. Moore's test for carotin in fat or oleomargarine is specific not alone for carotin added artificially but is also for the carotin natural to animal fats. In this test carotin is not dissolved out of the fat, but is merely decolorized by the ferric chlorid added. The reaction involved is a reduction of the iron and the simultaneous oxidation of the carotin.

The possibility of determining whether carotin has been added to butter fat or oleomargarine is discussed.

Separation and estimation of polysulphids and thiosulphate in lime-sulphur solutions, S. D. AVERITT (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 7, pp. 623-627).—The author, at the Kentucky Experiment Station, submits analytical data obtained from a comparative study of the direct iodine titration procedure of Harris (E. S. R., 25, p. 414), the method described by Thompson and Whittier (E. S. R., 32, p. 410), and two modified procedures, both of which are similar to the method of Harris, excepting that in the one tenth-normal hydrochloric acid is used instead of iodine for the monosulphur equivalent titration and in the other no attention is paid to the monosulphur equivalent titration.

"The experiments described and data presented in this paper afford new proof that calcium polysulphid in solution can be quantitatively decomposed by iodine solutions and thus eliminated from a solution containing thiosulphate, preparatory to the accurate determination of the latter."

The same result may be accomplished by means of dilute hydrochloric acid and elimination of the hydrogen sulphid formed by boiling. Sodium nitroprussid can be used as an internal indicator to show the end point of the disappearance of the sulphid in the titration with iodine. The accuracy of the iodine-titration method of Harris is confirmed.

A rapid and accurate procedure for weighing the precipitated sulphur in the iodine and hydrochloric-acid titrations of a lime-sulphur solution is proposed.

Sulphur fungicides, G. P. GRAY (*Off. Rpt. Sess. Internat. Cong. Vit.*, 1915, pp. 160-174).—The author discusses the subject under the following topics: Source of the world's supply of sulphur, refining methods, kinds of sulphur, use of dry sulphur, soluble compounds of sulphur, decomposition of sulphids and thiosulphates after application to the foliage, the home preparation of some sulphur fungicides, commercial preparations of the alkali polysulphids, and the compatibility of the sulphur fungicides.

Methods of preparation and relative value of Bordeaux mixtures, O. BUTLER (*Off. Rpt. Sess. Internat. Cong. Vit.*, 1915, pp. 151-160).—This is a general review of the subject, with some special reference to use on the grapevine. Some experimental data on the effect of temperature, strength in cupric sulphate, and ratio of  $\text{CuSO}_4$  to  $\text{CaO}$  on the rate of deterioration of Bordeaux mixtures; the relative toxicity of neutral and alkaline Bordeaux mixtures to the spores of *Phytophthora infestans* and *Plasmopara viticola*; the effect of the method of mixing on the adhesiveness of Bordeaux mixture; and the relative rate of

<sup>1</sup> Analyst, 12 (1887), p. 70.

<sup>2</sup> Analyst, 11 (1886), pp. 163, 164.

settlement at the end of two hours of 1 per cent Bordeaux mixture at the rate of 1:1 prepared in various ways are also submitted.

**The sterilization of fruit and vegetables for the home** (*Cent. Committee Nat. Patriot. Organs. [Pubs.], No. 4, (1916), pp. 22, figs. 7*).—This pamphlet briefly discusses the types of containers best suited for various fruits and vegetables, selection and preparation of materials for canning, various methods of sterilization, and general notes on defects often observed in the canned products.

**The sterilization of fruit and vegetables for the market** (*Cent. Committee Nat. Patriot. Organs. [Pubs.], No. 5 (1916), pp. 15*).—This pamphlet describes very briefly the stages in the production of canned goods for the market. The various processes of sterilization are indicated and time-tables for sterilization included.

**The recovery of potash from alunite**, W. H. WAGGAMAN and J. A. CULLEN (*U. S. Dept. Agr. Bul. 415 (1916), pp. 14, fig. 1*).—The geological occurrence and origin of alunite, the location, extent, and accessibility of the Utah alunites, the production of alum, and earlier methods for the production of potash from the mineral are briefly discussed.

Experimental data obtained in igniting 11 samples of alunite from the undeveloped but readily accessible area north of Marysvale, Utah, at different temperatures and subsequently leaching the residues with water are given. A temperature between 750 and 800° C. was found to be the best for the complete extraction of potash with the minimum amount of water. Above 800° a fixation of potash took place, especially in samples containing much silica.

In determining the influence of the fineness of the material on the subsequent extraction of potash it was shown that nothing was gained by grinding the material finer than will pass a 60-mesh sieve.

In connection with the economic considerations of the industry it is suggested that it would prove more economical to ship the mineral East, taking advantage of the lower freight rates on raw material, than to manufacture the finished products near the mines, since practically all the finished products have their market in the East.

**Hemp hurds as paper-making material**, L. H. DEWEY and J. L. MERRILL (*U. S. Dept. Agr. Bul. 404 (1916), pp. 25, figs. 4*).—This bulletin is divided into two parts, the production and handling of hemp hurds and the manufacture of paper from hemp hurds.

By proper treatment of the hemp hurds a paper stock was obtained from which a finished product that could be classed, according to official tests, as a number one machine-finished printing paper was produced. The bulletin itself is printed on some of this paper.

Data relative to the cooking of the hemp hurds and to the official tests of the finished product are submitted in tabular form. Industrial and economic aspects of the possibilities of the industry are also discussed.

**The effects of moisture introduced into the digester in the cooking of soda pulp**, S. D. WELLS (*Jour. Indus. and Engin. Chem., 8 (1916), No. 7, pp. 601, 602, figs. 4*).

## METEOROLOGY.

**Department of meteorology**, J. E. CHURCH, JR. (*Nevada Sta. Rpt. 1915, pp. 46-56*).—The work of this department of the station on forecasting frost from mountain tops, relation of mountains and forests to the conservation of snow, and the temperature survey and relation of topography to the occurrence of frost is summarized. An annotated list of meteorological publications issued during the year is given and the importance of permanently maintaining a department of meteorology in the station is discussed.

Analyzing the records at the summit of Mount Rose and at base stations of approximately 30 cold waves occurring during four years, it was found that five-sixths were felt both on the mountain and in the valley, but only one-third of these occurred sufficiently early on the mountain to give adequate warnings below (E. S. R., 35, p. 505).

From the snow studies the general conclusion is reached that "forests are a direct protection to the snow, those trees being most effective which allow the snow to reach the ground and yet protect it from the sun and wind. Fir trees have been found much superior to pine as conservers of snow, and forests with glades more satisfactory than continuous forests. Windbreaks on the lips of canyons and on exposed slopes are indispensable for holding the snow." The method of making estimates of stream flow based on the results of snow surveys is described.

Investigations on the relation of topography to the occurrence of frost in continuation of those previously reported (E. S. R., 27, p. 240) furnished data which "confirm earlier conclusions that, with elevation above the valley floor, there is a decrease both in the number of frosts and in the number of hours of orchard heating required, the decrease in the number of frosts with increase in elevation of 250 ft. in the Truckee Meadows having been found to be from 14 to 5 and in duration of freezing temperatures from at least 40 hours to 16. Also, except in abnormal years or in the coldest places, an average of two heatings each season will save the fruit. Moreover, it seems probable that at 28° F. or higher, except when the fruit is setting, no heating will be necessary to assure a moderate crop. . . . A simple rule has been devised for forecasting the probable maximum intensity of frost, namely, to subtract from the maximum temperature of the day on which the forecast is made the fall in temperature that normally occurs during the night when the weather is clear. In the spring at Reno this fall in temperature is 30 to 32°. Therefore, with a maximum temperature of 65° the minimum temperature should not be lower than 33°."

The studies on the effect of site and blossom development and frost injury are abstracted on page 40.

A method of forecasting the maximum summer level in Lake Tahoe from one to four months in advance, H. F. ALCIATORE (*U. S. Mo. Weather Rev.*, 44 (1916), No. 7, pp. 407-409).—A proposed method which has been tested for two successive seasons with satisfactory results is based upon the inches of snow (melted) falling monthly from December to April at nine stations in the Truckee-Tahoe watershed (519 square miles). Tables are given showing the average cumulative snowfall of these months at the nine stations during six seasons and the average cumulative changes in the level of the lake from December to July, 1910-1915. The average change in level is found to be proportional within certain limits to the average snowfall. Knowing the variation of the actual snowfall from the average, it is easy to calculate the probable change in lake level.

"The results obtained in 1915, a season of light snowfall, and those for 1916, a season of heavy snowfall, indicate that the proposed method is practical, and that the estimates based on snowfall records for four stations are of practically the same degree of accuracy as those based on a larger number of records."

The persistence of wet and dry weather, E. V. NEWNHAM (*Quart. Jour. Roy. Met. Soc. [London]*, 42 (1916), No. 179, pp. 153-162, figs. 3; *abs. in U. S. Mo. Weather Rev.*, 44 (1916), No. 7, p. 393).—Analyzing the rainfall records of several British stations by modern statistical methods, the author reaches the conclusion "that during a long spell of wet weather there are no grounds for

expecting finer conditions merely because the unsettled weather has lasted so long; and similarly that during fine weather the chances of continued drought become greater the longer the fine weather lasts, at any rate for spells of a length commonly met with. What happens when the length of the spell reaches a quite abnormal value must remain doubtful, but it seems reasonable to suppose the probability reaches a constant value."

Monthly Weather Review (*U. S. Mo. Weather Rev.*, 44 (1916), Nos. 7, pp. 381-429, pls. 8, figs. 4; 8, pp. 431-498, pls. 29, figs. 18).—In addition to weather forecasts, river and flood observations, and seismological reports for July and August, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during July and August, 1916; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 7.—Initial Investigations in the Upper Air of Australia, by G. Taylor (abs.); Classification of the Hydrometeors, by G. Hellmann; The Variability of Temperature, by A. Angot; Weather Forecasting in the United States; The Persistence of Wet and Dry Weather, by E. V. Newnham (abs.) (see p. 18); New South Wales Rainfall (illus.), by D. J. Mares; "Act of God" defined; Hurricane of July 5, 1916, at Pensacola, Fla., by W. F. Reed, jr.; Hurricane of July 5-6, 1916, at Mobile, Ala., by A. Ashenberger; The Tropical Hurricane of July 5, 1916, in Louisiana, by I. M. Cline; South Carolina Hurricane of July 13-14, 1916 (illus.), by J. H. Scott; A Method of Forecasting the Maximum Summer Level in Lake Tahoe from One to Four Months in Advance, by H. F. Alciatore (see p. 18); and Annual Rise in the Columbia River, by F. D. Young (abs.).

No. 8.—High Haze over the Southwestern United States during July to September, 1916, by H. H. Kimball; Atmospheric Refraction at Mount Hamilton, Cal. (illus.); On the Abnormal Propagation of Sound Waves in the Atmosphere (illus.), by S. Fujiwhara (abs.); Auroras Observed during August, 1916; Distribution of Precipitation in China during the Typhoons of the Summer of 1911 (illus.), by Co-Ching Chu; Radiation Equilibrium and Atmospheric Radiation, by R. Emden (abs.); A Tornado in Utah, by A. W. Stevens; The Government Safety-first Train, 1916 (illus.), by R. H. Finch; Graphical Method of Showing the Daily Weather, by E. T. Quayle (abs.); Tower Cloud at San Juan, P. R., by F. E. Hartwell; Extensions of U. S. Weather Bureau Service; and The North Carolina Earthquake of August 26, 1916, by R. H. Finch.

The fertilizing value of rain and snow, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1915, pp. 160-162).—The data for the eighth year of this investigation (E. S. R., 33, p. 716), are reported. These are taken to indicate that "the amount of soluble nitrogen compounds that may serve as food for crops as furnished annually by the rain and snow is not large and can not be regarded as an important factor in adding to the soil's store of nitrogen. . . . Since this nitrogen is furnished in an immediately available form, chiefly during the growing season, the precipitation does act as a fertilizing agent of some value."

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and J. S. SIMS (*Massachusetts Sta. Met. Buls.* 333, 334 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during September and October, 1916, are presented. The data are briefly discussed in general notes on the weather of each month.

## SOILS—FERTILIZERS.

Soil survey of Jefferson County, Arkansas, B. W. TILLMAN, R. R. BURN, W. B. COBB, C. LOUNSBURY, and G. G. STRICKLAND (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 39, fig. 1, map 1*).—This survey, made in cooperation with the Arkansas Experiment Station and issued September 25, 1916, deals with the soils of an area of 561,920 acres in southeast-central Arkansas, which comprises two general divisions, "an upland plain in the western part of the county and a lower river flood plain. The upland is prevailingly level, with small undulating to gently rolling areas. The lowland, or river bottom, section is a nearly level plain bordering the Arkansas River, with narrow extensions reaching into the upland along the smaller streams." "The drainage of much of the forested upland is deficient, owing to the level topography."

The soils are classed as upland or sedimentary soils and lowland alluvial soils. Twenty-two soil types of 10 series are mapped, of which the Portland clay and very fine sandy loam and the Caddo silt loam cover 17.8, 16.9, and 13.7 per cent of the area, respectively.

Kankakee County soils, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRETT (*Illinois Sta. Soil Rpt. 13 (1916), pp. 72, pls. 2, figs. 10*).—This is the thirtieth of the Illinois county soil reports. Kankakee County is located in eastern Illinois and has been covered completely by the Illinoian and the early Wisconsin glaciations.

The soils of the county are divided into upland prairie soils rich in organic matter, upland timber soils, terrace soils, late swamp and bottom land soils, and miscellaneous soil types. The brown silt loam prairie soils cover 35.74 per cent of the area, the brown sandy loam terrace soils 31.63 per cent, and the brown sandy loam prairie soils 13.12 per cent. "The variation among the different types of soil in Kankakee County with respect to their content of important plant food elements is very marked. The deep peat contains in the plowed soil of an acre thirty times as much nitrogen as the dune sand, and about five times as much nitrogen but only one-fifth as much potassium as the brown silt loam. The total supply of phosphorus in the surface soil varies from 560 lbs. per acre on the upland and 720 lbs. on the terrace, in the yellow-gray sandy loams, to 2,200 lbs. in the black clay loam terrace. The magnesium and calcium vary from about 3,000 or 4,000 lbs. in the lighter terrace soils to 15,000 or 20,000 lbs. in some other types. Some types contain an abundance of limestone, while others are practically neutral or slightly acid, and still others, such as the brown-gray silt loam on tight clay and the yellow-gray sandy loam (both terrace soils) and all upland timber soils, are distinctly acid in the surface, more strongly acid in the subsurface, and sometimes devoid of limestone even in the subsoil. More than 90 per cent of the soils of the county contain no limestone in the surface or subsurface to a depth of 20 in."

Reconnaissance soil survey of north part of north-central Wisconsin, W. J. GEIB, A. E. TAYLOR, L. R. SCHOENMANN, C. C. THOMPSON, T. J. DUNNEWALD, W. C. BOARDMAN, C. B. POST, and A. R. ALBERT (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 76, pls. 6, figs. 2, map 1*).—This survey, made in cooperation with the Wisconsin Geological and Natural History survey and issued September 15, 1916, deals with the soils of an area of 2,828,160 acres in north-central Wisconsin, the topographic features of which are characteristic of a glacial region. The surface varies from level to rolling and hilly. Including peat and rough stony land, 25 soil types of 9 series are mapped of which peat covers 20.4, Gloucester sandy loam 15.9, Spencer silt loam 15.1, and Gloucester fine sandy loam 13.9 per cent of the area.

Studies on soils, I, F. E. RICE (*Jour. Phys. Chem.*, 20 (1916), No. 3, pp. 214-227, fig. 1; *abs. in Chem. Abs.*, 10 (1916), No. 11, p. 1568; *Jour. Chem. Soc. [London]*, 110 (1916), No. 643, I, p. 360).—Laboratory experiments conducted at the New York State College of Agriculture with a number of soils collected from various parts of New York are reported.

The results are taken to indicate that "when so-called 'acid' soils are shaken with salt solutions, part of the cation of the salt is adsorbed and an equivalent quantity of bases from the soil is given up to the solution. The extracts, thus obtained, show greater acidity than that of the salt solutions themselves. This can be accounted for by the fact that one of the bases present is aluminum, which does not securely hold its share of the acid, but through hydrolysis hydrated aluminum oxid is formed along with equivalent quantities of free acid. The former being slightly ionized, possibly in a colloidal condition, and the latter more or less strongly ionized, the resultant solution is quite acid.

"Acid soils rarely contain water-soluble acid; but one case of mineral soil and one of muck soil was found that did yield an acid to water. Basic soils (as distinguished from 'acid' soils) gave up to salt solutions more base than is adsorbed. But as they are also found to give up to water quantities of base sufficient to produce solutions of alkaline reaction, this should not be considered entirely a phenomenon of basic exchange, but of simple solution of the excess of base."

Studies on soil colloids, I, Flocculation of soil colloidal solutions, M. I. WOLKOFF (*Soil Sci.*, 1 (1916), No. 6, pp. 585-601, figs. 3).—Experiments conducted at the Michigan Agricultural College to study the behavior of brick yard clay, silt loam soil, muck, peaty muck, and kaolin with respect to different electrolytes, in order better to understand the phenomenon of flocculation in the soil, are reported. Sixty-seven acid, salt, and alkali solutions were used in fifth-normal strength.

It was found that "besides the fact that the flocculating efficiency of different electrolytes with the same colloidal solution is different, the results show that the efficiency of the same electrolyte with the solutions from different soils varies considerably, depending largely upon the chemical composition of the soils. Schulze's valency law does not hold true with the soil colloidal solutions studied. Humic materials hinder the coagulating power of the electrolytes. It takes a greater amount of electrolyte for a flocculation of a more concentrated soil colloidal solution than that for a less concentrated one. In the flocculation of the soil colloidal solutions by the electrolyte, the reaction obeys, within the experimental error, the law of mass action."

Bacterial numbers in soils at different depths and in different seasons of the year, S. A. WAKSMAN (*Soil Sci.*, 1 (1916), No. 4, pp. 363-380, figs. 6).—A brief review of the work of others bearing on the subject is followed by a report of experiments conducted at Rutgers College on the bacterial numbers in loam and clay loam soils.

It was found that "the greatest number of bacteria were at a depth of 1 in. in the soils that are under shade all the year round. Garden soil gave on the average the largest numbers 4 in. from the surface. There was a regular decrease in numbers of organisms from a depth of 1 in. . . . down to a depth of 30 in. The greatest decrease in numbers between any two consecutive depths of sampling occurred between the first and the fourth, or the fourth and the eighth inches. The meadow soil gave the largest bacterial counts at a depth of 1 in. of all the soils. . . . The forest soil, though showing a high carbon and nitrogen content, gave the lowest bacterial counts. . . ."

"The numbers of bacteria in the soils studied were not governed either by the moisture content of the different soils or the nitrogen and carbon contents.

There was a gradual decrease in the lime requirement of the soils from the surface down to a depth of 30 in., except in the meadow soil. There was also a more or less gradual decrease in the nitrogen and carbon content of the different soils from the surface down to a depth of 30 in. . . .

"Frozen soil, though showing a high bacterial content, did not give the largest bacterial numbers through the year. . . . The time of maximum bacterial numbers during the year varied with the different soils throughout the year; no two soils showed their maximum bacterial content at the time of any one sampling."

A list of 30 references to literature bearing on the subject is appended.

Some factors that influence nitrate formation in acid soils, E. B. FRED and E. J. GRAUL (*Soil Sci.*, 1 (1916), No. 4, pp. 317-338, pl. 1).—Experiments conducted at the Wisconsin Experiment Station with neutral silt loam, acid sand, acid silt loam, and acid peat soils are reported. "The following phases of nitrification were investigated: (1) A study of the occurrence of nitrate-forming bacteria in acid soils and their relation to the organisms commonly found in neutral soils, (2) a comparison of nitrification of organic and inorganic substances in acid and neutral soils, and (3) a comparison of the effect of calcium carbonate on ammonification and nitrification of organic substances. . . .

"It was found that the formation of ammonia from casein takes place so rapidly in acid soils that for several weeks after the nitrogenous substance is added the production of nitrates is not limited by lack of ammonia. The formation of nitrates in acid sand and acid peat takes place very slowly. In acid silt loam or the neutral silt loam nitrification takes place much more rapidly. The feeble nitrifying power of the sand and peat, as shown by inoculating these soils with an active culture of the nitrifying bacteria, is largely due to the condition of the soil. Apparently the nitrifying flora of silt loam when transferred to a neutral soil is as active in the formation of nitrates as the flora from silt loam.

"In the case of the acid soils it seems that the nature of the compound to be nitrified plays an important part. For example, in acid soils organic nitrogen nitrifies much more rapidly than nitrogen from ammonium sulphate. In non-acid soils the reverse is true—ammonium sulphate nitrifies more rapidly. This is true regardless of the source of the nitrifying bacteria.

"It seems that acid soils do not possess a strain of nitrifying bacteria especially resistant to soil acidity. In the presence of organic nitrogenous substances, as casein and gelatin, calcium carbonate did not permanently increase the accumulation of nitrates. For a short interval, one or two weeks, calcium carbonate stimulates nitrate formation; later the reverse is true and there is a decided decrease in the treated series. Apparently the reduction of nitrates is largely due to bacteria. It has been found that in the treated soil there is an enormous multiplication of the nitrate-assimilating bacteria. When stored under conditions that prevent leaching, all of the soils showed a gain in nitrate nitrogen. It seems that in silt loam nitrification increases soil acidity, and thus it becomes necessary to add a basic substance in order to keep the process going. . . .

"Considering the data as a whole, it seems that under laboratory conditions the beneficial effect of calcium carbonate on plant growth must be accounted for by some processes other than the direct effect on nitrification."

Studies in sulfonation, P. E. BROWN and H. W. JOHNSON (*Soil Sci.*, 1 (1916), No. 4, pp. 339-362).—Further experiments conducted at the Iowa Experiment Station along the lines of those previously noted (E. S. R., 34, p. 19), which were planned "to throw some light upon the problem of the relative

effects of gypsum, acid phosphate, rock phosphate, alone and with gypsum, and monocalcium phosphate on sulfofication, on ammonification, and on the yields of oats in pots in the greenhouse," are reported. The soil used was a loam, high in organic matter and having a basic reaction.

It was found that "the sulphate content of the soil varied only slightly from one sampling to the next. There were no sudden or striking changes in the amount of sulphates present in the soil kept fallow in the greenhouse. The sulphate content of soils in the field is subject to the same influences as the nitrate content, but the effects are probably much less pronounced.

"Calcium sulphate, monocalcium phosphate, acid phosphate, rock phosphate, and rock phosphate plus gypsum increased the sulfofying power of the soil. The sulphate alone and phosphates alone had greater effects than combinations of the two materials, as in acid phosphate. All the materials used increased the ammonifying power of the soil, but the differences between the effects of the various substances were not pronounced. The rock phosphate had less effect, however, than the other materials.

"The sulfofication tests and ammonification tests did not always run parallel, although very similar effects of the materials used on the two processes were noted. The phosphorus fertilizers, except monocalcium phosphate, increased the yield of oats, the acid phosphate to a greater extent than the rock phosphate. The sulphate had no effect on the crop yield. . . .

"The crop yields, sulfofication, and ammonification results were not always parallel. In general it appeared that on this soil increases in sulfofication were not necessarily parallel with increases in yields. The ammonification results were not conclusive, but indicate that materials supplying plant food constituents which are lacking in the soil may be of double value because of increases in the production of other plant food constituents in an available form."

Further experiments with a heavy black woodland soil, a typical river bank sand in sod, two humus soils, and a river terrace cornfield soil are also reported, the purpose of which was to ascertain whether the 10-day incubation period allowed the greatest differentiation between the sulfofying powers of soils from different sources and under varying treatments. "Shorter periods of incubation were eliminated . . . and the tests were carried out at 7, 10, 12, and 14 day periods." The effects of gypsum, calcium carbonate, and magnesium carbonate on sulfofication were also studied.

It was found that "in the use of the free-sulphur-fresh-soil method for testing the sulfofying power of soils the incubation period should be 14 days at room temperature to give the most conclusive results. Ten days' incubation gave the relative sulfofying powers of soils quite accurately, but the differences were much more distinctive for the longer period.

"Calcium sulphate in ordinary applications had no detrimental effect on sulfofication, but very large applications might decrease the rate of oxidation of sulphur. Calcium carbonate in ordinary applications on acid soils increased sulfofication considerably and even in excessive amounts affected sulphur oxidation favorably. Magnesium carbonate in small amounts increased sulfofication, but in large amounts depressed it even below that in the same soil with its acidity unneutralized. Magnesium carbonate and calcium carbonate in combination exerted a beneficial influence on sulfofication when used in small amounts. Larger applications, however, depressed the oxidation of sulphur. The effects of the combined material were less than those of the calcium carbonate alone."

Some effects of litter on the fermentation of manure, W. E. TOTTINGHAM (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 6, pp. 511-515, figs. 4).—Experiments conducted at the Wisconsin Experiment Station on the chemical changes

in a fermenting mixture of manure and shavings, as compared with straw-littered manure and unlittered manure, are reported. A basal manure prepared by mixing one part by weight of fresh horse manure with two parts fresh cow manure and litters prepared by sifting finely cut oat straw, oak shavings, and Georgia pine shavings to uniform size, were used. Twenty-five lbs. of manure were mixed with 2 lbs. of litter.

It was found that "the loss of total organic matter during 12 weeks of fermentation ranged from 33 to 51 per cent. It was most rapid and greatest in the straw-littered manure, where bacteria were most numerous."

The water-soluble organic matter, ranging from 10 to 13 per cent of the total organic matter in the fresh manures, decreased continuously during 12 weeks of fermentation with the loss of from 60 to 80 per cent of the original amount, the loss being most rapid during the first two weeks. Humus ranging from 11.3 to 15.5 per cent of the total organic matter in the fresh manures decreased continuously, but more gradually than the water-soluble organic matter, during 12 weeks from 26 to 35 per cent. The losses from the littered manures were nearly equal and about one-third greater than from the control manure.

The water-soluble ash, ranging from 37.5 to 40.9 per cent of the total ash in the fresh manures, decreased gradually in all of the manures during 12 weeks of fermentation. The decrease ranged from 14 to 30 per cent of the amount originally soluble, being less in the straw-littered manure than in the other lots.

"The total nitrogen increased in all the manures until the fourth week of fermentation, the gains ranging from 8 per cent of the original amount in the control manure to 20 per cent in the straw-littered manure. More or less rapid loss of nitrogen occurred from the fourth to the eighth week of fermentation. After twelve weeks a net loss of nitrogen obtained in all of the manures. This net loss ranged from 3 to 13 per cent of the original amount of nitrogen, being less in the straw-littered manure than in the other manures.

"The water-soluble nitrogen decreased rapidly in all of the manures during the first four weeks. It suffered greater loss than any other constituent investigated, its curve being quite similar to that of the total organic matter. This constituent formed from 41.4 to 48.4 per cent of the total nitrogen at the beginning of the investigation. Losses of the water-soluble nitrogen ranged from 77 to 90 per cent of the original amounts and were somewhat greater in the shavings-littered manures than in the other lots.

"Humus nitrogen formed from 46.8 to 56.8 per cent of the total nitrogen in the fresh manures. Losses of this constituent ranged from 2 to 10 per cent of the original amounts, being greatest in the control manure. The fluctuation was similar in all of the manures, the humus nitrogen decreasing 10 to 20 per cent during the first four to eight weeks of fermentation and then gradually increasing.

"Ammoniacal nitrogen formed only 0.7 to 1.2 per cent of the total nitrogen at the beginning of the experiment. It rose to a maximum value in the control and shavings-littered manures during the first two weeks of fermentation, thereafter rapidly decreasing to about the original value after four weeks. In the straw-littered manure, on the other hand, the maximum production of ammonia was attained and passed gradually at about the fourth week. Ammoniacal nitrogen reached its greatest value in the control manure. In all cases, however, its values, ranging from 0.5 to 6.6 per cent of the total nitrogen, were too low to allow the placing of great importance on its fluctuations."

**Fertilizer experiments, F. T. SHUTT** (*Canada Expt. Farms Rpts. 1915, pp. 95-110*).—A number of different fertilizer experiments begun in 1913 at Fred-

erickson, N. B., and Kentville, N. S., and in 1914 at Agassiz, B. C., are reported, from which the following conclusions are drawn:

"A judicious and rational use of fertilizers may in a very large number of instances, be depended upon to yield a profit. Injudiciously applied a monetary loss may result. With certain crops, especially potatoes and roots, the yield may be largely increased by fertilizers, frequently doubled. The profit obtained, over and above the cost of fertilizer, should always be calculated, and not merely the increase in yield noted. . . . In general, it is advisable to use a complete fertilizer. . . .

"Fertilizers give increases in crop yields on many types of soil; even those soils which are considered fairly rich frequently yield increases, though these increases may not in all cases show a profit after deducting the cost of the fertilizer. Large dressings of fertilizer do not necessarily mean large increases in yield or large net profits. In experiments with potatoes, the profitable application has seldom exceeded 400 lbs. per acre. . . .

"The manipulation of fertilizer formulas to meet the specific requirements of certain crops, as frequently practiced and advertised by fertilizer manufacturers is of little significance."

**Protein decomposition in soils**, E. C. LATHROP (*Soil Sci.*, 1 (1916), No. 6, pp. 509-532).—Experiments to determine the changes taking place in dried blood in a fine sandy loam soil are reported.

"The ammonification of the dried blood in the soil during the first 86 days was very rapid, after which time the amount of ammonia produced and the rate of ammonification decreased markedly until the end of the experiment. At the end of the experiment the rate of transformation of hydrolyzable nitrogen into ammonia nitrogen in the soil was but about 10 per cent of the rate observed after the decomposition had been proceeding for 18 days. During the 240 days of the experiment 79 per cent or more of the nitrogen of the dried blood proteins was converted into ammonia nitrogen.

"The ammonia produced during the decomposition of the dried blood was derived from (1) the hydrolytic cleavage of the proteins of the dried blood, as evidenced by the rapid vanishing of the amid compounds from the soil during the first five days of the experiment; and (2) from the decomposition by the micro-organisms of the products resulting from the hydrolytic cleavage of the proteins. . . . With the exception of the amid compounds, lysin seems to have disappeared most rapidly and completely from the soil. The monoamino acids contributed about 89 per cent of their nitrogen to the formation of ammonia, and arginin and histidin each contributed about 83 per cent.

An analysis of the figures obtained by the Van Slyke method points to the generation of new protein materials in the soil. This is indicated by (1) the unequal loss of monoamino acids and hydrolyzable nitrogen from the soil during the early stages, (2) by an increase in amid nitrogen during the early stages, (3) by an increase in histodin nitrogen during the early stages, (4) by an increase in arginin nitrogen during the later stages, and (5) by an increase in lysin nitrogen during the later stages. This new form of protein seems to be more resistant to the action of the micro-organisms than were the proteins of the dried blood, since the amid compounds of the dried blood vanished very largely from the soil in five days, but the amid compounds produced in the soil decreased only to the extent of 57 per cent during the remaining 222 days of the experiment, and also since the lysin of the dried blood almost entirely disappeared from the soils during the first 86 days of the experiment, but during the last 154 days of the experiment a continual increase in this form of nitrogen was observed.

"Protein-like substances, nonextractable by distilled water but extractable by 1 per cent sodium hydroxid solution, were isolated from the soil after the dried blood had decomposed for 240 days."

A list of 60 references to literature bearing on the subject is appended.

**Potash salts, 1915, W. C. PHALEN** (*U. S. Geol. Survey, Mineral Resources of the United States, 1915, pt. 2, pp. 95-133*).—This bulletin gives a general review of domestic conditions with reference to the production and sources of potash, together with a brief description of processes involved in production, and simple tests for potash by W. B. Hicks.

It is stated that in 1915 soluble potash salts were produced in this country valued at \$342,000. "By-product potash from cement manufacture has become a reality at Riverside, Cal. Potassium sulphate from alunite was first placed on the market late in October, 1915, at Marysvale, Utah. An important production of potash salts is announced from Jesse Lake, near Hoffland, western Nebraska. Some potash was marketed in the form of dried kelp, which, however, must be considered of organic rather than mineral origin. Without much doubt, potash salts were produced in small quantity from feldspar or other silicate rocks and incorporated into mixed fertilizers without intermediate refinement. . . .

"Active operations are in progress in California at Searles Lake and at Keeler, on the shore of Owens Lake, and the by-product bittern at the solar evaporation plants on San Francisco Bay has also received some attention. In Utah, near Great Salt Lake, as is reported, one company is erecting a plant and another plant will soon be begun at the south end of the lake. An additional plant is also planned for Marysvale for work on alunite. . . .

"The imports of refined potash salts (all from Germany), which include the 80 per cent chlorid used in agriculture, were about one-fourth in 1915 what they were in 1913, the last normal year, and the imports of kainit and manure salts were about 3 per cent of those in 1913. All the imports of potash salts taken together amounted in 1915 to about one-tenth of recent imports under normal conditions."

Attention is also drawn to what appear to be promising foreign potash deposits in Spain and Chile.

A bibliography of 56 works bearing on the subject is appended.

**The oxidation of sulphur in soils as a means of increasing the availability of mineral phosphates, J. G. LIPMAN, H. C. McLEAN, and H. C. LINT** (*Soil Sci., 1 (1916), No. 6, pp. 533-539*).—Experiments conducted at the New Jersey Experiment Stations with pure sea sand, tenacious red silt loam, and medium loam soil to determine the influence of sulphur oxidation on the availability of rock phosphate are reported. Five gm. of sulphur and 15 gm. of rock phosphate were added to 100-gm. quantities of the soils.

It was found that "elementary sulphur is readily oxidized in soils containing sulfofying bacteria and offering favorable conditions for the development of these organisms. The oxidation of sulphur in soils may lead to the accumulation of large quantities of sulphuric acid. The sulphuric acid formed in the oxidation of sulphur by bacteria readily reacts with basic substances. Tricalcic phosphate, when added to soils or soil mixtures in which sulfofication is active, may react with the sulphuric acid formed, and may then furnish available phosphoric acid to crops. The facts recorded above justify the claim that compost heaps in which sulfofication is active may be utilized for the production of available phosphoric acid out of insoluble phosphates."

**The influence of liming on the productiveness of certain soils, F. T. SHUTT** (*Canada Expt. Farms Rpts. 1915, pp. 110-115*).—Chemical analyses of acid soil from Cap Rouge, Quebec, are reported, the results of which are taken to indicate

that the soil is relatively rich in the essential elements of fertility but markedly deficient in lime. Plat experiments with barley, oats, wheat, peas, and roots showed that liming at the rate of two tons per acre was markedly beneficial to barley and peas, and slightly beneficial to oats, wheat, and roots.

**Fertilizing materials,** F. T. SHUTT (*Canada Expt. Farms Rpts. 1915, pp. 115-127*).—Analyses of limestones, crushed clam shells, marls, wood ashes, mucks, peats, river and tidal muds, and certain by-products from manufacturing processes, are reported.

### AGRICULTURAL BOTANY.

**Agriculture and native vegetation in Peru,** O. F. COOK (*Jour. Wash. Acad. Sci., 6 (1916), No. 10, pp. 284-293, figs. 2*).—Opportunity for studying the relations of agriculture to forest vegetation in southern Peru and Bolivia having been afforded, the author has given an account of the biological conditions favoring forest growth, the present and former forest flora in the Andes, the habits of surviving native trees, the influence of forest fires, and the agricultural habits of the people.

The vegetation of a desert mountain range as conditioned by climatic factors, F. SHREVE (*Carnegie Inst. Washington Pub. 217 (1915), pp. 112, pls. 37, figs. 18*).—Results are given of a study covering several years of the ecology of the Santa Catalina Mountains, near Tucson, Ariz. The author recognizes three prominent divisions, desert, semidesert or shrub, and forest regions. The vegetation of each region is described, and an attempt is made to correlate the plant life with the climatic factors, which were carefully determined.

**Characters of plants grown in salt water and heredity,** P. LESAGE (*Rev. Gén. Bot., 28 (1916), No. 326, pp. 33-44*).—The author carried on a series of experiments during 1911 to 1915 to determine whether the differences observable between *Lepidium sativum* grown in surface water and that grown in sea water or weaker concentrations of salts are persistent and hereditary.

It is stated that of the various modifications produced in the specimens grown in salt water, so far as yet studied, only three (admittedly correlatives) appear to show a tendency to persist, namely, decreased size, diminished proportion of large seeds, and diminution of the average size of the seeds.

**Note on an orderly dissimilarity in inheritance from different parts of a plant,** W. BATESON and CAROLINE PELLEW (*Proc. Roy. Soc. [London], Ser. B, 89 (1916), No. B 612, pp. 174, 175*).—Reporting a continuance of studies previously noted (*E. S. R., 34, p. 41*), the authors state that they have followed up the suggestion given by the fact that in the intermediate forms previously described the characters may change progressively with growth, the lower parts being more typelike, the upper more roguelike, while only the lowest leaves of the  $F_1$  plants show any influence of the type parent. These observations suggest that when the offspring consists of a mixture of types and rogues, the types may be derived from the lower, and the rogues from the upper, parts.

Having in 1915 saved the upper and the lower pods separately from many pea plants, the bulk of which were reserved for further tests, the authors made a preliminary trial with a few seeds. As a result, it is thought that a segregation takes place in the soma of the plant such that the type elements are present especially in the lower parts, as had been surmised from the  $F_1$  generation. It is, therefore, considered probable that the rogues which are derived directly from typical plants are derived predominantly from the apical pods.

**A hybrid between *Tripsacum* and *Euchlæna*,** G. N. COLLINS and J. H. KEMPTON (*Jour. Wash. Acad. Sci., 4 (1914), No. 5, pp. 114-117*).—It is stated that in studying the heredity of maize and related plants, a fertile hybrid be-

tween *E. mexicana* and *T. dactyloides* has been secured, previous attempts having always given negative results, though *Euchlæna* freely hybridizes with maize.

Of the four hybrid seeds planted April 8, 1913, only one germinated. The seedling was found to resemble the male parent, *E. mexicana*, in practically all discernible characters, and this resemblance continued throughout the life of the plant. This plant is regarded as remarkable on account of the profound morphological differences between the parents (one of which is moreover strictly annual, the other perennial, requiring several years to mature), and the completely patroclinous characters of the hybrid.

Patrogenesis, a form of inheritance with the characters of the female parent completely excluded—a cross between two genera of grasses, *Tripsacum* and *Euchlæna*, G. N. COLLINS and J. H. KEMPTON (*Jour. Heredity*, 7 (1916), No. 3, pp. 106–118, figs. 8).—The one patroclinous hybrid reported above was grown from a *Tripsacum* seed to maturity in the greenhouse, carefully guarded, and self-pollinated, producing a quantity of seed. The first generation plants were pollinated from a Florida *Euchlæna* and from two very late varieties of tropical corn, all these pollinations being successful. A few seeds representing the results of each class of pollinations were planted in the greenhouse in December, 1913, but gave only 7 plants, one of which failed as a result of structural abnormalities which are described. During the early stages, the remaining 6 plants behaved much as did the first generation plant, but later differences developed in some cases, which are described. Further plantings (from the original lots of seed from the first generation plant), transplanted to the open or made directly in open soil, developed no abnormalities.

In 1915, experiments were conducted near San Diego, Cal., the long growing season affording the first opportunity for the hybrid to mature undisturbed. It is stated that the crosses between *Tripsacum* and *Zea* showed usually complete resemblance to the female parent, and it is thought possible that *Zea* pollen may have induced parthenogenesis in the *Tripsacum* plant. Studies to test this hypothesis have been instituted.

In attempting to explain the fact that a cross between *E. mexicana*, male, and *T. dactyloides*, female, has been carried over three generations without exhibiting any characteristics of the female parent, it is thought that two hypotheses may be presented, namely, that the characters of the female parent have been completely masked by those of the male, or that the male nucleus developed in the ovary to the complete exclusion of the female, representing in a way the counterpart of parthenogenesis. The observed facts and circumstances are thought to exclude the first hypothesis. If the second alternative be adopted, we are compelled, the authors hold, to look upon the results of the cross as a special type of inheritance not previously recognized. No true hybridization or conjugation between the two nuclei appears to have taken place. The term patrogenesis is proposed as appropriate in such cases, also as serving to place this phenomenon in proper contrast with parthenogenesis. This is considered to have been rendered appropriate by the occurrence of what appears to be true parthenogenesis in *Tripsacum* when pollinated with maize.

Studies on the influence of temperature on the growth of the root of *Pisum sativum*, ISABELLA LEITCH (*Overseas. K. Danske Vidensk. Selsk. Forhandl.*, No. 2 (1916), pp. 109–112).—Experiments are reported on the growth of the roots of peas at various temperatures. The minimum temperature for growth was found to be  $-2^{\circ}$ , the maximum  $42.5^{\circ}$  and the optimum  $29^{\circ}$  C. The maximum amount of growth for a very limited time occurred at  $30.3^{\circ}$ .

The influence of temperature variations on the respiration of plants, L. BLANC (*Rev. Gén. Bot.*, 28 (1916), No. 327, pp. 65–79).—The author has

tested the relations between changes in respiration as noted in embryos of *Phaseolus vulgaris*, etiolated stems of *Vicia faba*, and young leaves of *Secale cereale* as related to different temperatures and to changes of temperature, either gradual or more or less abrupt, and to restoration of former temperatures.

It is stated that sudden variations of temperature do not of themselves constitute an excitant as regards respiration in plants. Between the respiratory activity corresponding to a given temperature and that corresponding to a different temperature the transition is gradual, and the course of respiration change corresponds to that of temperature.

The decrease of permeability produced by anesthetics, W. J. V. OSTERHOUT (*Bot. Gaz.*, 61 (1916), No. 2, pp. 148-158, figs. 6).—The present paper gives details, with discussion, of some experiments previously reported (E. S. R., 28, p. 732) and of later researches on tissues of *Laminaria saccharina*, as regards their electrical conductivity under the influence of photosynthesis.

It is stated that increase of permeability (except in case of alcohol within certain limits) corresponds to a permanent injury and is not reversible. It is not, therefore, to be regarded as a characteristic effect of the anesthetic. The characteristic effect of anesthetics is regarded as being connected in some way with decrease of permeability. It is stated that a decrease of permeability may result in the decrease of irritability, which is the characteristic effect of an anesthetic.

Swelling and germination of seeds, J. TRAUBE and T. MARUSAWA (*Internat. Ztschr. Phys. Chem. Biol.*, 2 (1915), No. 4-5, pp. 370-393).—It is stated that the behavior of starchy seeds in relation to electrolytes and nonelectrolytes as described corresponds essentially to that of starch.

Swelling and differences therein are more considerable in case of such nitrogenous legumes as peas than in such cereals as barley. Narcotics retard swelling, presumably on account of their flocculating effect on nitrogenous material. The fact that acids and also indifferent narcotics retard swelling of plant seeds is thought to indicate that swelling does not play the principal part in germination. Indifferent narcotics cause more commonly a genuine narcosis, but in some cases they cause irreversible injury. Acids still more often give the latter result, the law of mass action possibly applying here to colloidal phenomena. Some fatty acids appear particularly injurious. In certain low concentrations citric acid greatly hastens germination of seeds. No constant relation was noted between injury to germination and growth.

The influence of oxygenated water on germination, E. DEMOUSSY (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 12, pp. 435-438).—Reporting a study of the kind of influence exerted by oxygen in favoring the germination of aged seeds, the author states that 7-year-old seeds of garden cress which failed to germinate when partly immersed in distilled water gave germination rates of from 30 to 40 per cent in water containing oxygen, the time required for germination being from three to ten days. The oxygen is thought to have retarded the development of micro-organisms which find partial or total protection from antiseptics in mucilagenous layers of the seeds. The oxygenated water was ineffective at low temperatures. Seed which failed to germinate in pure water at 27° C. gave a germination rate of 25 per cent in moist sand at that temperature, a result attributed to the increased access of oxygen.

Studies on water transfer in plants, L. JOST (*Ztschr. Bot.*, 8 (1916), No. 1, pp. 1-55, figs. 12).—It is stated that the cut stump of a plant gives up much less water than is taken up at first by the portion which has been cut away when this is placed in water, or than the intact leaf requires. The cause of this alteration is thought to lie in the interruption of the connections in the tracheal

tissue, and the failure of negative pressure is the cause of the decrease or cessation of withdrawal of water from the root. Higher negative pressures give a greater flow than lower, but the increase does not bear a simple proportion to the change in pressure. The flow from the cut stump may be greatly weakened in spite of increased negative pressure by cooling the lower part or immersing it in water or hydrogen.

The separated top, immediately and for a while after its separation, shows a considerable increase of water uptake, indicating that tensions exist in the intact plant. These afterwards reach a state of equilibrium in connection with the atmospheric pressure on the cut surfaces and the attainment of a uniform inflow of water, which some plants maintain for some time under constant temperature.

Studies on the decomposition of cellulose in soils, I. G. MCBETH (*Soil Sci.*, 1 (1916), No. 5, pp. 437-487).—This paper deals mainly with bacteria which dissolve cellulose, a considerable number of which were found in the 69 soils of southern California examined by the author. In working out descriptions of new species, a number of which are systematically discussed, an attempt is made to bring out individual characteristics as concisely as possible. A summary is given of the more important morphological and cultural features of the bacteria.

The cellulose agar plate method is said to be the most satisfactory for isolating pure strains of bacteria, filamentous fungi, and Actinomycetes, which dissolve cellulose and all of which grow under anaerobic, but much better under aerobic, conditions. Filamentous fungi are thought to play a much more important part in cellulose destruction in the humid soils of the eastern part of the United States than in the semiarid soils of southern California, where the rapid destruction of cellulose is thought to be due to favorable climatic and cultural conditions rather than to the unusual activity of the cellulose-dissolving soil flora.

The primary sugar of photosynthesis, H. H. DIXON and T. G. MASON (*Nature [London]*, 97 (1916), No. 2425, p. 160).—It is stated that while microchemical tests on the assimilating cells of certain plants indicate a considerable concentration of hexoses in the chloroplasts or in the protoplasm immediately surrounding them, other lines of experiment suggest that while sucrose is concentrated in the large vacuoles invertase is held apart from it in the protoplasm.

The view that the formation of sucrose is a preliminary step in the production of hexoses in the leaf is not considered a necessary deduction from the work of some other investigators named. It is thought more probable that the hexoses are formed from formaldehyde in the chloroplast, and that at a certain concentration condensation into sucrose takes place due to invertase or some saccharogenic enzym, the sucrose thus formed being passed into the vacuole and stored there. The volume of the protoplasm available for the hexoses being small as compared with that available for sucrose, the increase in the total percentage of the hexoses formed will be relatively small on exposure of the leaf to light as compared with the increase in sucrose. This is therefore regarded as insufficient proof of sucrose being the primary sugar. The recognition of the localization of the various substances in the cell is considered to furnish an explanation as to how the sucrose-hexose ratio of the cell is maintained in the presence of invertase.

The biochemical function of magnesium in plants, L. BERNARDINI (*Ann. R. Scuola Sup. Agr. Portici*, 2. ser., 12 (1914), pp. 361-389).—It is thought that magnesium in connection with calcium plays an important part in the process of vegetative growth in relation to the assimilation of phosphoric acid and in

the transportation of phosphorus to the growing and maturing seeds. The same is thought to be true in the alimentation of the embryo and the nutrition of very young shoots, in which magnesium seems to serve as a vehicle for the transfer of phosphoric acid. Certain observations are thought to indicate the necessity for the presence of magnesium in the shoots in connection with the formation of chlorophyll.

The influence of various salts on the growth of soy beans, J. W. SHIVE (*Soil Sci.*, 1 (1916), No. 2, pp. 163-170, fig. 1).—As a result of experiments to test the influence of various salts on the growth of *Glycine hispida* and *Solanum nigrum*, employing the same pots of soil in the same way, it was found that the seeds of the latter failed to germinate and that germination and growth of the former were greatly impaired. These experiments, which are described, are regarded as suggestive but not conclusive.

Studies in the nutritive relations of our cultivated plants, L. HILTNER, G. GENTNER, and K. MAISCH (*Landw. Jahrb. Bayern*, 3 (1913), No. 10, pp. 485-583, figs. 10).—This contains an account of a study by these authors on the growth of plants in nutritive solutions, and of another by the first two authors named on the influence of humus in plant nutrition.

Diastase activity and invertase activity of bacteria, G. P. KOCH (*Soil Sci.*, 1 (1916), No. 2, pp. 179-196, figs. 4).—The author states that enzymes determined as diastase and invertase are secreted by bacteria in culture solutions in determinable quantity. Enzymes secreted by bacteria in different solutions show considerable differences in their activity, which also varies from day to day.

Bacteria appear to produce a factor which may prevent starch hydrolysis and sucrose inversion. There seems to be no direct correlation between hydrolytic enzyme secretion and protein decomposition, but a correlation appears to be possible between the utilization of protein decomposition determined as ammonia and the formation of acid. Enzyme activity varies considerably with different species of bacteria and also with different cultures of the same species. No correlation was found to exist between hydrolytic enzyme secretion and the rotation of polarized light, the percentage of reducing compounds, the formation of acid, and the number of organisms. Bacteria may increase or may decrease the rotary power of the solution, but do not produce in the solution a surplus of reducing compounds. There is an increase in bacterial numbers up to the third day, after which *Bacillus coli* shows irregularity, while *Bacterium mycoides* shows a decrease.

Quantitative media for the estimation of bacteria in soils, R. C. COOK (*Soil Sci.*, 1 (1916), No. 2, pp. 153-161).—An account is given of experiments as carried out with different media and soils.

It is concluded that sodium asparaginate agar, albumin agar, and urea ammonium nitrate agar will usually give a greater colony development than other media now in use for bacteriological work. Albumin agar in which the albumin is dissolved in sodium hydroxid is said to give results more consistent than those obtained with albumin in water solution. Considerably higher bacterial counts were obtained from a five-day than from a three-day incubation period. Equally good results as regards sterilization were obtained from flowing steam or steam standing under a pressure of one atmosphere. Differentiation in blood meal and hay infusion agars was marked. The behavior of some soils toward the several media may vary as regards both degree and direction of the influence exerted in the comparative tests.

A method for the renewal of plant nutrients in sand cultures, A. G. MCCALL (*Ohio Jour. Sci.*, 16 (1916), No. 3, pp. 101-103, fig. 1).—The author describes a method which he has devised by which it is claimed that seedlings may be

grown in sand and the nutrient solution kept constant, renewed, or modified almost as readily as in water cultures.

Preliminary revision of the genus *Inga*, H. PITTMER (*U. S. Nat. Mus., Contrib. Nat. Herbarium*, 18 (1916), pt. 5, pp. 173-223+XI, pls. 25).—A preliminary revision of the genus *Inga*, many of the species of which are important leguminous trees, is given. A considerable number of new species are described.

## FIELD CROPS.

[Field crops work at the Canada stations and farms in 1914, J. H. GRISDALE ET AL. (*Canada Expt. Farms Rpts.* 1915, pp. 618, 619, 673, 674, 692-694, 703, 736-741, 747, 751, 760-762, 773, 774, 787, 788, 796, 801-803, 813, 814, 841, 847, 854, 855, 867-947, 1015-1100, 1153-1191, 1193-1210, pls. 7).—A report of the continuation of work previously noted (*E. S. R.*, 33, p. 728) and a detailed account of work already mentioned (*E. S. R.*, 33, p. 34), including mainly variety and cultural tests with grain and forage crops, flax, potatoes, and tobacco.

Variety and cultural tests were conducted with winter and spring wheat, emmer, spelt, oats, barley, winter and spring rye, peas, beans, flax, and buckwheat at the experiment stations, substations, and farms in Ontario, Prince Edward Island, Nova Scotia, Quebec, Manitoba, Saskatchewan, Alberta, and British Columbia. The results obtained are presented in tables with brief comments. Similar work in the same localities with forage crops included tests of corn for grain and silage, peas and oats for forage, timothy and clover for hay and for seed, grass and clover mixtures, vetches, orchard grass, western rye grass, red fescue, reedtop, awnless brome grass, and other grasses, annual hay crops including different kinds of millet, alfalfa, sainfoin, clovers, turnips, mangolds, carrots, and sugar beets.

Results of variety and culture tests with tobacco and of observations on seed bed management conducted in the Provinces of Ontario and Quebec are reported in tabular form and described, and notes are given on the harvesting and curing and on the different varieties entering into the trials. The work on seed bed management has been noted from another source (*E. S. R.*, 35, p. 233). In a fertilizer experiment the maximum yields of 1,537 lbs. each per acre were obtained on plats receiving 250 lbs. of sulphate of ammonia, 180 lbs. of sulphate of potash, and 100 lbs. of superphosphate; and 250 lbs. of sulphate of ammonia, 150 lbs. of sulphate of potash, and 80 lbs. of superphosphate per acre. It is concluded that nitrogen and potash are the important elements and that only a comparatively small quantity of phosphoric acid is required on the soils under test.

The nicotine content of the different varieties of tobacco under experiment, as determined at the tobacco station at Farnham, Quebec, is reported in a table, together with the results of soil analyses for the different plats on which the tobacco was grown. The tobacco station at Harrow, Ontario, tested rye, hairy vetch, and clover as cover crops in connection with tobacco culture, and studied the use of fertilizers and the value of soil disinfection in seed bed management. A combination of nitrate of soda, sulphate of potash, and superphosphate mixed in equal proportions by weight and applied at the rate of 0.1 of a lb. per square foot gave excellent results as a plant-bed fertilizer. Sowing Burley beds on the same area for more than one or two years was found unsatisfactory unless the soil had been changed or sterilized. A cold bed with glass covering gave plants about ten days earlier than a cold bed with cotton covering. A test carried on at Walkerville, Ontario, gave no conclusive evidence in favor of the use of acid phosphate as a means of controlling root rot.

A report on the status of the tobacco industry in the different tobacco producing sections of Ontario is presented.

[Work with field crops at the Canada experimental farms in 1914], W. L. GRAHAM ET AL. (*Canada Expt. Farms Rpts. 1915*, pp. 171-349, 355, pls. 9).—A summary of the results here reported has been noted from another source (E. S. R., 33, p. 830).

Summary report of state experiment farms and cooperative experiment farms, 1915, (*Cheyenne, Wyo.: State Bd. Farm Comrs., 1915*, pp. 70, pl. 1).—Notes are given on the cultivation of flax and cereal and forage crops at Archer, Jireh, and Sheridan with only the natural rainfall, and at Lyman, Eden, and Torrington with irrigation.

Cereal experiments at the Akron field station, Akron, Colorado, G. A. McMURDO (*U. S. Dept. Agr. Bul. 402 (1916)*, pp. 34, figs. 11).—This bulletin describes the topography, soil, and climate of the district in which the field station is located and presents in tabular form with discussions the results of tests with 17 varieties and strains of winter wheat, 44 of spring wheat, 16 of oats, and 19 of barley, conducted from 1908 to 1915, inclusive. Rye, emmer, flax, proso, and grain sorghums were also tested but on a smaller scale.

Winter wheat gave better results than spring wheat and the durum wheats produced higher average yields than the common spring wheats. Crimean winter wheat produced the highest average yield, 22 bu. per acre, of any winter wheat tested during the eight years and Kharkof ranked second with 21.6 bu. The highest average yield of any spring wheat obtained in the eight years, 22.4 bu. per acre, was produced by Pelissier, a durum wheat, followed by Velvet Don with an average yield of 21.5 bu. and Arnautka with 21.1 bu. Ghirka spring wheat, of the Fife group, yielded 18.6 bu. Tests in seeding winter wheat at different rates were not satisfactory but it is believed that 3 pk. per acre is the best rate. Date-of-seeding tests indicated that the period from September 15 to October 15 is the best for sowing winter wheat. Tests with spring wheat indicated that sowing from 3 to 4 pk. per acre is likely to give the best yields.

The best varieties of oats tested for the eight years were Kherson, an early variety, with an average yield per acre of 44.7 bu. and Colorado No. 37, a mid-season variety, with a yield of 43.9 bu. The late varieties yielded much less than the early or midseason sorts. A comparison of different rates of seeding of Kherson oats indicated that the best yields are obtained by sowing 4 pk. per acre.

The best varieties of barley compared during the 8-year period were Hannchen, giving an average yield of 38.7 bu., and Coast, yielding 38 bu. The 2-rowed group of barleys gave higher average yields than the 6-rowed group.

Winter rye proved inferior in value to wheat. Winter emmer was not hardy and gave an 8-year average yield of 14.2 bu., while White spring emmer averaged 30.3 bu. per acre. Flax did not compete successfully with weeds, and most varieties of grain sorghums failed to mature. The 5-year average yield of Manchu Brown kaoliang was 15.4 bu. per acre, and the average yield of proso for the same period was 23.1 bu. Proso seemed to be valuable mainly as a catch crop.

Cereal experiments at the Judith Basin substation, Moccasin, Montana, N. C. DONALDSON (*U. S. Dept. Agr. Bul. 398 (1916)*, pp. 41, figs. 17).—This bulletin is a report on experiments with cereals conducted cooperatively since 1908 by the Office of Cereal Investigations of the U. S. Department of Agriculture and the Montana Experiment Station. In addition to the tabulated results of experiments with wheat, oats, barley, and flax and their discussion, descriptions are given of the Judith Basin, mainly with reference to topography

and climate, and of the substation located there. The altitude of the locality is given as 4,300 ft. The annual average precipitation at Moccasin from 1898 to 1915, inclusive, was 16.66 in., and the average seasonal rainfall from April to July, inclusive, for the same years, 9.41.

The leading varieties of the different cereals grown in the experiments are compared in the following table:

*Annual and average yields and average farm value of the leading variety of each of the cereals grown at the Judith Basin substation.*

Crop and variety.	Yield per acre.						Acre value of crop
	1910.	1911.	1913.	1914.	1915.	Average.	
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	
Kharkof winter wheat.....	2,880	2,478	1,866	1,470	2,964	2,331	\$31.08
Pelissier spring wheat.....	630	1,698	1,920	1,590	2,530	1,673	21.58
Sixty-day oat.....	1,036	2,278	2,409	1,883	2,998	2,126	23.70
White Smyrna barley.....	590	2,490	3,360	2,400	3,854	2,540	28.42
Nepal barley.....	984	1,800	2,220	1,542	2,508	1,810	18.24
Russian flax.....		1,070	930	723	1,282	1,002	27.09

The results of the experiments were in favor of sowing winter wheat at the rate of 3 pk. per acre and of the period from August 10 to September 10 as the best time for sowing. The highest yields of spring wheats were obtained from varieties of durum wheat, of which Pelissier was the best producer. Marquis was the leading variety of the common spring wheats. With reference to the time of sowing, the best results were obtained from sowing all spring wheat, oats, and barley as early in the spring as soil and climatic conditions permitted. Sowing flax between April 15 and May 1 is considered as being probably most satisfactory. The quantity of seed per acre recommended for spring wheat and small-kerneled, early varieties of oats, such as Sixty-Day, is 4 pk.; for hulled varieties of barley 5 pk.; naked varieties of barley 4 pk.; and flax 20 to 25 lbs. Sixty-Day oats averaged about 16 bu. per acre more than later maturing varieties.

Emmer and spelt did not give so good yields as barley and oats, and proso millet did not prove promising. Early varieties of brown kaoliang and broom corn did not mature seed.

A pasture survey in southeastern Ohio, H. W. HAWTHORNE and C. W. MONTGOMERY (*Mo. Bul. Ohio Sta., 1 (1916), No. 9, pp. 282-288, figs. 2*).—This article deals with a survey of the pasture conditions in eastern and southeastern Ohio, made in 1913 in cooperation with the Office of Farm Management of the U. S. Department of Agriculture. Information was gathered through correspondence and conferences with a number of farmers.

The pastures were designated as rotation pastures and permanent pastures. The prevalent rotation was corn, oats, and wheat, with the wheat sown to red clover and timothy, and maintained as pasture from one to nine years, during which fertility was kept up chiefly through the use of commercial fertilizers on the preceding crop. Most of the permanent pastures were not seeded for that special purpose, although in some cases mixtures of timothy, orchard grass, blue grass, and clovers were used. Fertility was maintained in a few instances by top-dressing with commercial fertilizers or manure. One farm reported the clipping of the stubble each year after harvesting, which resulted in thickening the sod and increasing the carrying capacity of the fields.

An irrigation experiment with clover, sugar beets, potatoes, and wheat, C. S. KNIGHT (*Nevada Sta. Rpt. 1915, pp. 24-28*).—This experiment was conducted in 1914 on soil varying from a sandy loam to a clay loam. In the irrigation of clover 6, 9, and 12 inch applications were made at various stages of wilting. The results showed that clover can not be allowed to reach the wilting stages without materially decreasing the yield of hay, and that on soils such as that of the experiment applications of from 9 to 12 in. given before the plants show need of water are essential for the heaviest production.

Potatoes were given 3, 6, and 9 inch applications of water before and at the time the plants showed a tendency to wilt, when all leaves wilted down once, and when all plants failed to revive at night. Where the plants were allowed to wilt to the extent where they failed to revive at night it was found impossible to produce a satisfactory crop. The highest yields were produced with the smallest application of water, although little difference was shown in yield where the crop received two, four, or five 3-inch applications. The highest starch content was secured with the smallest applications when the plants were never allowed to wilt, and in the three stages of wilting the highest starch content was obtained with the largest applications.

An experiment similar to the one with potatoes was conducted with sugar beets with the exception that 2, 4, and 6 inch applications of water were made. Where no irrigation was given until the plants wilted down and failed to revive at night, an unsatisfactory crop was produced. With 2-inch applications the beets in all stages of wilting showed a higher sugar content than those receiving the greater amounts of water. The purity of the sugar was greatest in the beets irrigated only after all plants had wilted down once.

Wheat was given 3, 4½, and 6-inch applications of irrigation water at the five-leaf, boot, bloom, milk, and dough stages. A comparison was made of plants receiving an irrigation at each of the five stages, with plants in which an irrigation was omitted in each of the five stages, with plants in which irrigation was omitted at any two of the five stages, and with those that received the same amount of water in only two applications—one before and one after heading. Where one irrigation was omitted, the omission of the application at the five-leaf stage gave the best results, with a difference in yield of less than 3 per cent in the three highest producers. Where two irrigations were omitted satisfactory results were noted only where the irrigations were omitted at the five-leaf and dough stages. Four 6-inch irrigations with one application omitted at the five-leaf stage yielded 25.8 per cent more than five 6-inch applications. Omission of irrigations between the boot and milk stages greatly decreased the yield of grain. With only two irrigations the 6- and 12-inch applications proved most satisfactory. Of the results in yield 83 per cent were in favor of the 6-inch applications, the difference being greatest where two irrigations were omitted at the five-leaf and dough stages.

The different depths affected the soil moisture only to a slight extent when two irrigations were omitted, but when only one irrigation was passed over an average difference of 12.3 per cent was noted in the first 3 ft. in favor of the 6-inch application. In the first 2 ft. with 6-inch applications the average soil moisture content before irrigation at the milk stage was 20 per cent less where two irrigations were omitted than where only one irrigation was omitted.

The average nitrogen content of the plants for all plats at the different stages of growth is given as follows: Five-leaf 4.37 per cent, boot 2.75 per cent, bloom 2.09 per cent, milk 1.4 per cent, and dough 1.25 per cent.

An investigation of varieties of cereal and forage crops and their improvement, C. S. KNIGHT (*Nevada Sta. Rpt. 1915 pp. 28-32*).—Notes are given on the growth and yield of varieties of alfalfa, potatoes, beets, field peas, corn, wheat, oats, barley, and millets.

The cultural value and identification of Spanish alfalfa, G. GENTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 13 (1915), No. 10, pp. 136-139*).—Comparative tests of different kinds of alfalfa are reported, indicating that in general Spanish alfalfa grown in Germany is less productive than that grown from domestic and other seed sources. Turkestan alfalfa also ranked low in yield, standing next to the Spanish. The impurities found in the Spanish alfalfa seed, including inert material and weed seeds, are enumerated as a means of its identification.

Composition of the maize plant, J. W. INCE (*North Dakota Sta. Bul. 117 (1916), pp. 3-32, figs. 7*).—A study was made in 1914 and 1915 to determine the yield of mineral matter and organic constituents of the maize plant under North Dakota conditions, and to ascertain the best stage of cutting corn for silage. Analyses were made when the plants were in tassel, when the corn was in the milk, in the dough, when glazed, and when fully ripe. In 1914 the work was conducted at the main station and the substations at Dickinson, Edgeley, and Williston, while in 1915 it was pursued only at the main station. At Dickinson and Williston, Northwestern; at Edgeley, Minnesota No. 23; and at the main station, Mercer, were the varieties grown. The climatic conditions of the seasons are described, the meteorological data are presented by means of graphs, and the analytical results are shown in tables.

The composition of the corn at the different stages was compared with similar data for corn grown in New York and Indiana. According to these figures corn grown in North Dakota does not give as high yields of protein, fat, and carbohydrates as corn grown in New York or Indiana and the increase of these substances is not so rapid. It was found that the maximum yields for North Dakota were practically reached at the glazed stage, even a loss of protein being observed when the corn was ripe, while the data for the corn grown in New York and Indiana indicated a steady increase in all the constituents up to the maximum at the time of maturity.

Analyses of agricultural yield.—I. The spacing experiment with Egyptian cotton, 1912, W. L. BALLS and F. S. HOLTON (*Phil. Trans. Roy. Soc. London, Ser. B, 206 (1916), No. 327, pp. 103-180, figs. 11*).—The investigations reported were entered upon to establish a statistical analysis of the yields of cotton in terms of the stages of the plant's development. The studies dealt mainly with the effects of spacing, the time of sowing, and the character of the season on Egyptian cotton grown at Giza. The numerical data recorded during the cultivation of the crop are presented in detail in a series of tables and graphs, and include records of daily flowering and weekly bolting for the 20 different spacings compared and of boll weight, seed weight, and ginning outturn, together with computed statistics of yield ratios.

It is concluded from the results that the yield of cotton is primarily dependent on the number of flowers formed. The normal extensions of the root system of an isolated cotton plant was found capable of utilizing more than 2 square meters of soil surface of soil which is more than 2 meters deep. As the plants in cultural practice have only 0.18 of a square meter, or less, each allowed them, most of the phenomena of field crop physiology in the fruiting season are regarded as traceable to the consequent interference of one root system with another. The yield per unit area of the conventional spacing practiced in Egypt was determined as the maximum obtainable under the limitations in field cultivation.

The sources of error in field experiments with cotton are enumerated as follows: Soil variation, especially below 1-meter depth, insufficient frequency of observation whereby accidental episodes can not be distinguished from normal sequences, fluctuation of single plants, heterogeneity of commercial varieties, and normal physiological variations from day to day.

**Analyses of agricultural yield.—II.** The sowing-date experiment with Egyptian cotton, 1913, W. L. BALLS and F. S. HOLTON (*Phil. Trans. Roy. Soc. London, Ser. B, 206 (1915), No. 333, pp. 403-480, figs. 18*).—The experiment described dealt with the yield obtained by planting Egyptian cotton at weekly intervals from February 15 to April 11, including nine planting dates. Five plats were planted each week and each plat contained a check row of about 150 plants. Statistical records, which are appended in tabular form, were obtained for the field germination, weekly height of the main stem, daily flowering, and weekly ripening of bolls.

It is concluded that the data derived from the work show the existence of an optimum date for planting which appears to be constant, or practically so, from year to year. It was found that plantings made before this date did not gain the corresponding average which might be expected, and that they might be even inferior. The result is explained by the assumption that some depressing factor is brought to bear on the early plantings which has less effect on later ones. This depressant factor is believed to be primarily an internal one induced within the plants. In this connection the authors show that internal water shortage leaves an after effect on the plant which can only be removed slowly by a restoration of an ample water supply. It is stated that this effect when severe may require the lapse of several weeks for its complete disappearance and in some instances it may never be quite overcome.

"It is probable that this after effect is due to the production of toxic excreta in such cells as grow under deficient water supply. . . . The fall in the growth rate of the main stem which takes place in Egypt after midsummer would seem to be due to the same factor, reasserting itself as the sole controller of growth . . . when the plants have grown so large that their closely packed root systems are inadequate to meet the loss by transpiration.

"The action of the depressant factor is essentially confined to a single group of meristematic cells. Thus the growth of the main stem may be checked but that of the younger flowering branches may continue, they having been developed from areas which did not produce the toxin, because they were not growing at the time when the toxin-provoking conditions were operative."

It is further concluded that the origin of this depressant factor can be attributed to the temperature of the soil, which is the only factor of the environment whose seasonal fluctuations are practically uniform from year to year.

**Early and midseason potatoes at Wisley, 1915** (*Jour. Roy. Hort. Soc. 41 (1915), No. 2, pp. 290-304*).—Descriptions are given of 107 varieties of potatoes under trial. The varieties giving the best results were Duke of York and Midlothian Early varieties; General Joffre, Old Yellow Ashleaf, Sharpe Express, Sir John Llewelyn, Stirling Castle, and Winchill Seedling, medium early varieties; and Arran Chief, Great Scot, Stretton No. 20, and Wolfe Secundus, mid-season varieties.

**Sugar beets for factory purposes, F. T. SHUTT** (*Canada Expt. Farms Rpts. 1915, pp. 155-160*).—The percentage of sugar and of solids in the juice of sugar beets, the coefficient of purity, the average weight per root, and the yield per acre are recorded for five varieties grown at the Dominion Experimental Farms in 1914. The average percentage of sugar in the juice of sugar beets grown on these farms from 1902 to 1914, inclusive, is also given in a table, and notes re-

garding the soil and season at the several farms and stations for 1914 are compiled.

**Sudan grass in Kansas, G. E. THOMPSON** (*Kansas Sta. Bul. 212 (1916), pp. 3-29, figs. 8*).—This bulletin presents a general discussion of Sudan grass culture, and reports the results of experiments relating to date and rate of seeding, yielding capacity with and without irrigation, comparative feeding value, and the usefulness of the grass for pasture. The chemical analysis of Sudan grass seed as compared with wheat, corn, oats, and Kafir corn, and the composition of Sudan grass hay as compared with alfalfa and prairie hay and sorghum fodder are given in tables. The experimental work was carried on at the main station and the various substations and partly in cooperation with the United States Department of Agriculture. The principal diseases attacking Sudan grass together with control measures are briefly described.

The results indicated in general that Sudan grass is primarily a hay crop which is adapted to practically all soils of the State excepting those very wet and poorly drained, extremely alkaline, or extremely sandy. It is stated that the crop may be planted and handled in much the same manner as the ordinary sorghums and that, when planted in cultivated rows, 2 to 4 lbs. of seed per acre are needed, while when broadcasted or drilled, 15 to 35 lbs. per acre give the best results. It was found that 2 to 3 cuttings for hay or one seed crop may be secured each season and that 400 lbs. of seed per acre or 2 to 4 tons of hay constitute an average crop. Comparative analyses showed that Sudan grass hay, while richer in protein than prairie hay, is not so rich as alfalfa hay. In feeding tests with dairy cows and with beef cattle and work horses and mules carried through the winter uniformly good results were secured. The results of pasture tests indicated this grass to be valuable in a limited way for grazing purposes and that it may have an important place on many farms in furnishing grazing for hogs.

**The time to seed wheat in Kansas, L. E. CALL, S. C. SALMON, and C. C. CUNNINGHAM** (*Kansas Sta. Bul. 213 (1916), pp. 3-16, fig. 1*).—Experiments to determine the best time to seed wheat were begun in 1911 at the station and at six places in as many counties in the main wheat-producing area of the State where the Hessian fly is likely to cause serious loss. In each test a series of plats was sown at weekly intervals for six or seven weeks, beginning the second week in September. The outcome of the tests is given in tables and is briefly discussed.

It was found that in central and eastern Kansas wheat may be sown late enough to avoid most of the injury from Hessian fly and yet early enough on well-prepared ground to secure a good growth before winter. The dates given as best for seeding are as follows: Northeastern Kansas from about September 25 to October 3, southern central Kansas from about September 25 to October 7, and northern central Kansas from about September 20 to October 1. It is pointed out that as the time for seeding western Kansas depends on the rainfall, the land should be prepared early and seeded when in proper condition to insure germination and good growth. It is further stated that wheat may be sown later in rich soil on well-prepared ground than in soil that is poor or poorly prepared, as early and thorough preparation not only destroys many of the flies but enables the wheat to make a more rapid, vigorous, and resistant growth.

Tests to observe the effect of the time of seeding on the tillering of wheat showed that the rate of seeding made very little difference in the yield when the sowing was done before September 28. After this date the higher rates of seeding gave the best yield.

**Liming the wheat crop, C. E. THORNE** (*Mo. Bul. Ohio Sta., 1 (1916), No. 9, pp. 277-281, figs. 3*).—This article presents some results obtained from experi-

ments at Wooster comparing the effects of liming upon the yields of wheat on fertilized and unfertilized and manured plats. It is concluded that liming is of fundamental importance on this soil, and that neither manure nor other combinations of fertilizers will produce a full yield without lime.

**Seed analyses made during 1912-1915,** MARY H. JAGGER and E. M. STODDARD (*Connecticut State Sta. Rpt. 1915, pt. 6, pp. 497-513*).—The work for the period is described and notes on the samples of clover, alfalfa, and grass seeds examined are given. The results of analyses of red clover seed samples secured in 1913, and including the number of noxious weed seeds and other foreign seeds other than weeds per pound, are tabulated, and germination and vitality tests with different kinds of seeds, including vegetable and tree seeds, are described.

Reported data on the vitality and sprouting capacity of onion seed show that the varying number of samples of Connecticut grown seed tested from year to year, from 1894 to 1912, inclusive, and less than one year old, contained on an average 75.5 per cent of seeds capable of sprouting. A comparison of onion seed samples less than one year old with samples more than one and less than four years old, showed a loss of vitality with the increasing age of the seed. Nineteen samples of Connecticut-grown onion seed separated into heavy and light seeds showed an increase in germination ranging from 2.5 to 36 per cent in favor of the heavy seed.

## HORTICULTURE.

**Report from the division of horticulture for the year ended March 31, 1915,** W. T. MACOUN ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 581-617, 619-673, 674-692, 694-702, 704-736, 741-746, 747-750, 751-759, 762-773, 774-786, 788-795, 797-800, 803-813, 815-841, 842-846, 848-854, 855-863, pls. 12*).—A detailed report on results secured in 1914 in the breeding, cultural, and variety experiments with fruits, vegetables, forest and ornamental trees, and herbaceous plants, conducted at the Central Farm, Ottawa, and at the various branch experimental farms and stations in Canada. A summary of the more important results has appeared previously in bulletin form (*E. S. R., 33, p. 236*). Analyses of several commercial brands of arsenate of lead are also included.

[**State insecticide and fungicide laws**] (*U. S. Dept. Agr., Insecticide and Fungicide Bd. Serv. and Regulatory Announcement 13 (1916), pp. 101-152*).—This comprises a compilation of state laws dealing with the manufacture and sale of insecticides and fungicides as amended to date. The subject matter is based upon publications and other information relating to such laws furnished to the Federal Insecticide and Fungicide Board by state officials.

**The relation of fruit growing to soil fertility,** R. C. THOMPSON (*Arkansas Sta. Bul. 123 (1916), pp. 3-8*).—In the spring of 1906 young peach and apple orchards were set out at the station, and data were collected annually for a period of nine years on the amount of plant food taken from the soil by individual trees of the orchards. A total of 90 apple trees and 36 peach trees were analyzed during the experiment. The following table shows the total amount of plant food taken up by peach and apple trees for the production of wood and leaves, as well as an estimate of the amount of plant food that was returned to the soil by the dead leaves and other means during the nine years of the experiment. The data are calculated on a basis of 100 peach trees and 40 apple trees per acre.

*Losses in soil fertility per acre in growing fruit trees.*

	Peach trees.			Apple trees.		
	Phos- phoric acid.	Nitro- gen.	Potash.	Phos- phoric acid.	Nitro- gen.	Potash.
Total plant food taken up by trees in the nine years...	Lbs. 50.83	Lbs. 215.90	Lbs. 237.60	Lbs. 9.26	Lbs. 28.10	Lbs. 27.22
Total plant food retained in trees at the end of the ninth growing season.....	27.67	87.97	60.18	6.73	15.26	14.25
Total plant food returned to the soil by leaves, etc., during the nine years.....	23.16	127.93	177.42	2.53	12.84	12.97

From these data the author concludes that the total loss for the growth of an acre of trees to maturity is scarcely more in quantity, though different in proportion of elements, than that contained in 100 bu. of corn.

Analyses were made of the fruit to determine the total loss in soil fertility by the removal of a crop, and the average percentage composition of all samples of fruit analyzed was used in making the following calculation:

*Comparison of the amount of plant food removed from the soil by peach and apple fruit and corn.*

Crop.	Yield per acre.	Fruit or grain.	Dry matter.	Phos- phoric acid in crop.	Nitro- gen in crop.	Potash in crop.
	Bu.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.
Apple.....	500	25,000	3,675	6.61	13.45	43.05
Peach.....	500	25,000	3,500	11.90	22.30	59.50
Corn.....	50	2,800	2,503	19.88	46.20	15.96

From the data secured as a whole it appears that apple production will exhaust the soil much more slowly than corn or grain crops. Peach trees resemble apple trees in their demands, the principal difference being that more plant food is required for a crop of peaches than for a crop of apples. In the presence of sufficient moisture and other conditions suitable for fruit culture the principal soil fertility and fertilizer problems confronting the orchardist is the building up of the soil by means of commercial fertilizers and manure to a normal state of fertility. For this purpose it was concluded that 8 or 10 tons of barnyard manure applied per acre every three years followed by green manure crops and proper tillage is sufficient.

[The effect of site on blossom development and frost injury], J. E. CHURCH, JR. (*Nevada Sta. Rpt. 1915, pp. 52, 53*).—Observations made of a few orchards during the spring of 1915 indicate that when frost occurs with wind orchards which are protected from the wind by hillsides or other screens suffer much less injury than when the exposure is complete. Frost injury increased with the stage of development of the blossoms.

Orchard rejuvenation in southeastern Ohio, F. H. BALLOU (*Ohio Sta. Bul. 301 (1916), pp. 3-40, figs. 23*).—In this bulletin the author reviews previous experiments in orchard fertilization and culture conducted by the station (E. S. R., 28, p. 47) and gives the results of more recent experiments in orchard fertilization.

The completion of a 5-year period of work in orchard fertilization at three different locations in southeastern Ohio has confirmed previous conclusions that

the thin upland soils of central, eastern, and southern Ohio are seriously deficient in nitrogen, and that the application of readily available nitrogen in such cases surprisingly transforms the starving, unproductive orchards into those that are vigorous, productive, and profitable. There has been little evidence of additional benefit derived when acid phosphate and muriate of potash as sources of phosphorus and potassium have been combined with nitrate of soda, so far as tree growth or yield and appearance or texture of fruit are concerned.

Nitrate of soda has given more favorable results than slower-acting organic sources of nitrogen. The results of 4-year tests of fertilizers with a straw mulch as compared with double-rate fertilization without a mulch of straw have shown the heavier fertilization without mulching material to be most advantageous. This result is attributed chiefly to the beneficial results of nitrate of soda, which has encouraged the natural substitution of grasses and clovers in place of an almost worthless soil covering of weeds and poverty grass. These grasses and clovers cut and used as a mulch have yielded better returns than the straw mulch.

Although acid phosphate has been of little direct fertilizing value to the orchard, the experiments show that applications of acid phosphate used either alone or in combination with muriate of potash have caused the small scattering clover plants to increase noticeably in size and gradually take possession of the soil. After the clover had attained its maximum development, disappeared, and left in connection with the decaying roots a liberal store of available nitrogen, the better grasses began to come in. With the supply of nitrogen from the clover a marked improvement in wood growth, foliage development, and disposition to produce fruit was observed among the apple trees.

Relative to the practical application of this method of providing nitrogen by means of acid phosphate, the author points out that it is too slow for practical use where prompt results in fruit production are desired. It is suggested, however, that the use of nitrate of soda with acid phosphate in such a way as not to stimulate the production of the various grasses to the extent that the clover will be crowded or smothered out may prove to be the most economical method of renovating these hill soils. Experimental tests of such a combination have shown that where nitrate of soda at a rate of not above 200 lbs. in combination with 200 lbs. and upward of acid phosphate is applied evenly over the orchard, very nearly as good results are obtained from nitrate as where it is applied in a circle under the outer extremities of the branches, without counterbalancing the beneficial effects of the phosphate in clover encouragement.

A test of cultivation versus the grass-mulch method of culture was conducted for two years, with financial results slightly in favor of the grass-mulch method of culture.

Variation of internal structure of apple varieties, E. J. KRAUS (*Oregon Sta. Bul. 135 (1916), pp. 3-42, figs. 164*).—In connection with apple studies conducted at the station (E. S. R., 29, p. 541; 32, p. 855) considerable variation was found to exist in the internal structure of different varieties of apples. The author has undertaken a much more extended study of internal fruit structure. The present bulletin outlines the nature of this investigation, and contains a number of plates showing variations in internal structures of a number of different varieties of apples and pears. The more important differences are briefly noted, but no conclusions are drawn nor interpretations made of the data at this time.

Effect of pruning peach trees at different heights previous to planting in the orchard, M. A. BLAKE (*New Jersey Stat. Bul. 293 (1916), pp. 3-30, figs. 14*).—This bulletin reports the results of growth studies with peach trees pruned at various heights at the time of planting. Trees calipering  $\frac{1}{2}$ ,  $\frac{3}{4}$ ,  $\frac{5}{8}$ ,  $\frac{1}{2}$ , and  $\frac{3}{4}$  in.

were used in the experiments, and comparisons were made between trees dug in the fall and stored over winter in a nursery storehouse, trees dug in the spring and allowed to dry out through improper handling, and freshly dug trees. The following pruning treatments were used: Not pruned and cut back to 36, 30, 24, 18, 12, and 6 in. trunks, respectively. Observations were made at the close of the growing season and are here presented in tabular form and fully discussed.

The work as a whole is summarized as follows: "One-year-old peach trees of a  $\frac{3}{8}$  or  $\frac{1}{4}$  in. grade made the largest average total growth. The larger the trees the poorer is the growth when unpruned at planting time. The smaller the trees, the greater is the damage if the trees are allowed to become dry before planting.

"The largest average total growth regardless of the grade was made by trees cut to a 36 in. trunk when set except in the case of dried-out trees. Trees cut to 12 in. trunks when set made the next largest average total growth. The smallest average total growth occurred when trees were cut to 18 in. trunks when set.

"Trees of a  $\frac{3}{8}$  in. grade made the largest amount of growth when cut back to 6 in. trunks when set. Trees as large as  $\frac{1}{4}$  in. or larger were depressed in growth when cut back to 6 in. trunks.

"Trees in general failed to develop branches well upon the 12 to 24 in. section of the trunk. It was later observed that very few well-developed buds occur upon this section of the tree under average conditions. The largest total number of branches was found to occur in the lengths from 7 to 12 in. The largest average total number of branches of all lengths occurred in the 36 in. treatment, with the 12 in. treatment second. The number of branches of all lengths is, therefore, apparently correlated with the amount of growth.

"The unpruned trees developed the smallest number of branches that were more than 24 in. in length. The 36 in. trees developed the largest number of branches that were more than 24 in. in length. The 6 in. treatment resulted in the formation of the largest number of branches 40 to 50 in. in length. The 12 in. treatment gave the largest number of branches 37 to 40 in. in length. The 18 in. treatment gave the largest number of branches 30 to 36 in. in length. The 24 in. treatment gave the largest number of branches 25 to 30 in. in length.

"We may, then, conclude that the more severe the pruning the greater the tendency to produce long branches. It should be noted, further, however, that so-called main branches are reduced in number when the trees are cut to 6 in.

"One-year peach trees from the nursery start into growth best when planted in the orchard if there are well-formed buds just below the point where the tree is cut back. The number of such buds varies at different points along the trunk of a nursery tree. Buds are found to be most numerous at the 36 to 42 in. space followed in order by the 42 to 48 and the 0 to 6 in. spaces. Buds are found to be least numerous at the 6 to 12 in. space followed in order by the 12 to 18 and the 24 to 30 in. spaces.

"Peach trees at the time of planting should be pruned somewhat according to grade and the character of the stock, and not according to some definite height regardless of all other factors."

A financial statement of the experiment station peach orchard, C. A. McCue (*Delaware Sta. Bul. 113 (1916), pp. 3-21*).—This comprises a detailed survey of the cost of growing peaches in the station orchard of some 1,000 trees during the period 1908 to 1915, inclusive.

Starting out with an original investment for land of \$100 an acre the orchard was still in debt \$209.65 at the end of the sixth year. The combined profits

of the seventh and eighth years, or for the whole 8-year period, was \$2,280.52. The average yearly profit was \$29.81 per acre, which is equivalent to 29.8 per cent on the original investment of \$100 an acre or a 5 per cent return on an orchard valuation of \$596.20 an acre. The cost of raising a 16-qt. Delaware basket of peaches during the whole period was 34.472 cts., and the net profit per basket was 12.923 cts.

**Report of cranberry substation for 1915, H. J. FRANKLIN** (*Massachusetts Sta. Bul. 168 (1916), pp. 48*).—This bulletin contains a full report on the work of the cranberry substation at East Wareham for the year 1915 (*E. S. R., 33, p. 341*).

The usual weather observations were made during the year and experiments with tobacco shade cloth for frost protection were continued, with the general result, however, that its use for this purpose appears less advisable than the 1914 tests seemed to indicate. The difficulties connected with its manipulation on the bog are evidently considerable. The author is of the opinion that a cheaper and more certainly effective means of protection may be had on most unprotected bogs through flooding these areas by means of small pumping plants.

In connection with a study of fungus diseases extensive storage tests were conducted during the fall and early winter to determine the effects of some of the factors affecting the keeping quality of cranberries. The results of a number of these tests are here presented in tabular form. They show the relation of ventilation to rate of decay, water losses of cranberries in boxes of different construction and in different periods of the storage season, and injury to keeping quality of cranberries caused by their drop into barrels. Other storage tests and observations are also noted.

The tests as a whole show that while ventilation is a very important factor in retarding the development of rot, it is of doubtful economic value except in storage house construction. The most rapid development of decay takes place in the very first part of the storage season. Berries of poor keeping quality are usually shipped as soon as possible after they are picked and it is only with such fruit that the maximum benefit to be gained by superior arrangements for ventilation would be realized. In lieu of extensive ventilating equipment the thorough airing of the storage house on cool, dry days and the allowance of as much space in the storage of the fruit as possible is recommended. Special attention to the keeping down of temperatures appears to promise fully as great advantages as far as storage previous to shipment is concerned as can be obtained from special arrangements for ventilation.

Much injury is done to the keeping quality of cranberries by the bouncing of the berries in the separators commonly used and by their drop into the barrels in separating and screening. In view of their greater expense the use of less injurious separators appears to require the establishment of community packing houses. Although the barrel is the common method of shipping cranberries it appears to be undesirable for this purpose, both from the standpoint of mechanical injury and ventilation. The author is of the opinion that fruit to be shipped to the trade in the more distant parts of the country would be in a far more acceptable condition if crated and shipped in the uncleaned condition, to be prepared for market at central distributing points in the territory where it is to be consumed.

Experiments in resanding cranberry bogs were continued (*E. S. R., 31, p. 740*). The results with reference to quantity and keeping quality on the sanded and resanded plats are here presented and compared with the results secured in previous years. Briefly summarized, the plats have shown no very

definite effect on the quantity of fruit produced resulting from resanding or the lack thereof. The author concludes that the advantages gained by resanding are of such a general nature—a certain amount of frost protection and help in the control of the tip worm and girdler being the most evident—that they are not definitely determinable by means of plat experiments.

A résumé is given of the results secured from fertilizers with reference to the effect on quantity and keeping quality of cranberries from 1911, when the experiments were started, up to the present time. The data given indicate a moderate average increase in the quantity of fruit obtained during the five-year period from the fertilized areas as compared with that from the checks. Nitrate of soda appears to have impaired the keeping quality of the fruit somewhat, while no effect in this respect connected with the use of acid phosphate and sulphate of potash is apparent. Results on one of the limed plats suggest the inference that lime favors the development of some disease that is peculiar to the Early Black variety of cranberry. Experiments with fertilizers to determine the possibility of stimulating and increasing the setting of cranberry blossoms were continued, no very distinct advantage in quantity of fruit being shown by the fertilized areas. The berries from three of these plats were put in storage tests, and all showed an impaired keeping quality in comparison with the fruit from the checks.

With experience gained from the cranberry investigations as a basis, the author here presents and discusses for the consideration of Massachusetts growers a number of ideas relative to changes in bog management looking to more successful culture and marketing practices. The season's work with plant diseases and insects is noted on pages 51 and 54.

## FORESTRY.

Annual report of the director of forestry of the Philippine Islands for the fiscal year ended December 31, 1915, W. F. SHERFESEE (*Ann. Rpt. Dir. Forestry P. I., 1915, pp. 91, pls. 2*).—This is the usual progress report relative to the administration, investigation, management, and reconnaissance work for the year ended December 31, 1915. Data relative to applications for homesteads, purchases, and leases of public lands, timber cut by species, revenues, timber licenses, utilization of forest products from the public forests, and exports and imports of major and minor forest products are appended.

Report on state nurseries and plantations, T. N. BRODRICK ET AL. (*New Zeal. Dept. Lands, Rpt. State Nurseries and Plantations, 1915, pp. 32*).—A report of forest operations on the various state nurseries and plantations in New Zealand for the year ended March 31, 1916.

Report of the chief forest fire warden for the year 1915, G. H. WIRT (*Penn. Dept. Forestry Bul. 13 (1916), pp. 182*).—This includes a report on forest fires in Pennsylvania in 1915, activities dealing with forest protection, and a review of forest-fire legislation in the State by I. C. Williams.

Grass and woodland fires in Texas, J. H. FOSTER (*Bul. Agr. and Mech. Col. Tex., 3. ser., 2 (1916), No. 5, pp. 16, figs. 5*).—In this bulletin the author calls attention to the serious damage done, both to the agricultural and forestal industries of Texas, through grass and woodland fires, and gives the text of the laws of the State dealing with forestry and forest protection.

Importance of soil aeration in forestry, R. S. HOLE (*Agr. Jour. India, Spec. Indian Sci. Cong. No., 1916, pp. 27-32, pls. 5*).—In this paper the author discusses the damage that may be done to the seedlings of forest trees by insufficient soil aeration when the physical condition of the soil is apparently

suitable for growth and when the soil, although moist, is far from being saturated with water. The discussion is based upon results secured in experiments with seedlings of the sal tree (*Shorea robusta*).

A preliminary study on the culture of exotic forest species in Italy, A. PAVARI (*Ann. R. Ist. Sup. Forestal Naz. Firenze, 1 (1914-15), pp. 159-379*).—The author here presents the results of a survey of the distribution and climatic requirements of the more important timber species. The work was conducted with special reference to its application in subsequent attempts to acclimatize foreign species in Italy.

Notes on acacia, with description of new species, I, J. H. MAIDEN (*Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 3, pp. 463-513*).—This paper discusses the various species of acacia and describes a number of proposed new species.

Notes on Eucalyptus, with descriptions of new species, IV, J. H. MAIDEN (*Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 3, pp. 309-331*).—In continuation of previous papers (E. S. R., 34, p. 742), the author describes a number of new species of eucalypts and gives notes on some species previously described.

Eucalyptus australiana n. sp. (narrow-leaved peppermint) and its essential oil, R. T. BAKER and H. G. SMITH (*Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 3, pp. 514-525*).—A systematic description of narrow-leaved peppermint (*E. australiana* n. sp.), together with an account of its essential oil, including analytical tests made at the Technological Museum.

Notes on the tapping of Para rubber, W. G. FREEMAN (*Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 5, pp. 155-162*).—The author reviews the results obtained by modern tapping systems in various countries, and gives data showing the results of tapping experiments conducted at the St. Clair Experiment Station during the period 1911 to 1916, inclusive.

A new steam tree feller, J. SCRIMGEOUR (*Trans. Roy. Scot. Arbor. Soc., 30 (1916), pt. 2, pp. 126-128, pls. 2*).—The author describes and illustrates a new steam tree feller which has been successfully used in Scotland for a number of months.

Selling woodlot products on Michigan farms, E. H. FROTHINGHAM (*Lansing, Mich.: State, 1916, pp. 49, pls. 11*).—This bulletin is based upon a statistical survey of the wood-using industries of Michigan, conducted by the Forest Service of the U. S. Department of Agriculture in cooperation with the Public Domain Commission of the State of Michigan. It discusses the woodlot situation in Michigan, the common woodlot trees, marketing woodlot products destined for various industries, methods of conducting the sale, how to prevent the deterioration of cut woodlot products, and some of the principal uses of the common woodlot trees. A directory of Michigan firms buying woodlot products in the rough is included.

Forest products of Canada, 1915.—Pulpwood (*Dept. Int. Canada, Forestry Branch Bul. 58B (1916), pp. 12, pl. 1, figs. 4*).—A statistical account of the pulpwood industry of Canada for the year 1915, including comparative data for the previous year.

Proceedings of the twelfth annual meeting of the American Wood Preservers' Association, F. J. ANGIER (*Proc. Amer. Wood Preservers' Assoc., 12 (1916), pp. 432, pls. 2, figs. 52*).—In addition to the regular business pertaining to the association, the proceedings contain reports of the following papers and discussions given at the annual meeting, held in Chicago, January, 1916:

Creosoted Piling and Poles, by F. W. Cherrington (pp. 61-70); Methods of Creosoting Douglas Fir Timbers, by O. P. M. Goss (pp. 70-83); Vacuum Process

in Creosoting, by J. D. Isaacs (pp. 83-86); Notes on Measuring Devices and on Methods of Determining Cubical Contents per Charge, by C. W. Lane (pp. 86-91); Selecting and Buying Fuel, by W. H. Crady (pp. 91-104); The Foreign Creosote Oil Situation, by G. A. Lembecke (pp. 104, 105); Woods Suitable for Cross-ties, by R. Van Metre (pp. 106-109); Quantity of Zinc Chlorid per Tie or per Cubic Foot of Timber, and Method of Determining the True Strength of the Solution, by W. F. Goltra (pp. 109-117); Marine Borers from the Wood Preservers' Standpoint, by L. F. Shackell (pp. 124-135); Report of Special Committee on Specifications for Preservative for Wood Paving Blocks, by S. R. Church et al. (pp. 135-148); Discussion on Preservative Specifications for Wood Paving Blocks, by A. E. Larkin (pp. 148-164); Water Sampling in Creosote Oil (pp. 164-168); Report of Committee on Specifications for the Purchase and Preservation of Treatable Timber, by E. A. Sterling et al. (pp. 171-187); Fungi Which Grow on Untreated Ties or Untreated Wood, by H. von Schrenk (pp. 187-202); Treated Wood Block for Factory Flooring and Miscellaneous Uses, by C. H. Teesdale (pp. 202-210); Report of Committee on Wood Block Paving, by C. H. Teesdale et al. (pp. 210-225); Report of Committee on Service Tests of Wood Block Paving, by A. E. Larkin et al. (pp. 225-237); Discussion on Woods Suitable for Cross-ties, by C. P. Winslow and J. A. Newlin (pp. 238-247); Reclaiming Arid Lands, by F. H. Newell (pp. 247-257); Report of Committee on Service Tests of Cross-ties, by C. P. Winslow et al. (pp. 257-265); Durability Records of Cross-ties, by C. P. Winslow and C. H. Teesdale (pp. 265-333); Report of Committee on Service Tests of Bridge and Structural Timber, by H. M. Rollins et al. (pp. 333-342); Quantity of Wood Preservatives Consumed and Amount of Wood Treated by Wood-preserving Plants in the United States in 1915, by R. K. Helphenstine, jr., and H. S. Betts (pp. 380-408); and Bibliography of Wood-boring Crustaceans, by F. Moll (pp. 409-413).

An index to the contents of previous proceedings is appended.

## DISEASES OF PLANTS.

Pathological plant anatomy, E. KÜSTER (*Pathologische Pflanzenanatomie. Jena: G. Fischer, 1916, 2. cd., pp. XI+447, figs. 209*).—The author presents in this edition not only the material retained from the former one, which has been translated by Miss Dorrance (E. S. R., 34, p. 49), but also a considerable amount of new material, with a rearrangement of the general plan, bringing the work up to the date of its practical completion about August, 1914. There is also added a list of recent contributions by other authors extending to November, 1915.

Tumors in plants, E. F. SMITH (*Science, n. ser., 44 (1916), No. 1139, pp. 611, 612*).—The author reports having succeeded in producing small tumors in plants without the use of the crown gall organism (*Bacterium tumefaciens*) by means of substances which are by-products of bacterial growth. Small tumors are said to have been obtained repeatedly on several kinds of plants, and their presence is interpreted as being due to the fleeting chemical stimulus applied.

A paper describing in full the investigation is promised for early publication.

How to identify infectious plant diseases, S. F. ASHBY (*Jour. Jamaica Agr. Soc., 20 (1916), No. 1, pp. 6-12*).—This information, said to be available also in pamphlet form, relates, among other matters, to the symptoms, causation, and treatment of Panama disease or banana wilt, Bonnygate disease or banana bulb rot, cacao pod rot and red or purple canker, dieback of cacao, bud rot of coconut palm, and leaf dieback of coconut.

Report of the division of botany, H. T. GÜSSOW (*Canada Expt. Farms Rpts. 1915, pp. 949-990, pls. 11, figs. 2*).—An account is given of some administrative

features in connection with the enforcement of the destructive insect and pest act, investigations in plant pathology, economic botany, and a report of the St. Catharines field laboratory. The work reported in the administration of the destructive insect and pest act has consisted largely of inspection of potatoes for shipment.

In plant pathology, the diseases reported upon are principally those of potatoes, a number of which are described, and the results of experiments are given in some cases. Experiments on the effect of fresh manure on potato scab show that fresh horse manure increased the amount of scab more than any of the others used, while the use of sheep and hen manure resulted in the smallest amount of scab. A potato disease called net necrosis is briefly described. This is characterized by brownish discolorations of the fibrovascular bundles of the tubers. Some experiments were undertaken to determine whether tubers that showed this infection before planting would produce a crop free from the disease, and the results indicate that in almost every case the disease is hereditary. Some investigations on the control of *Rhizoctonia* or black scurf of potato, due to *Corticium vagum solani*, are reported in which it appears that treating seed tubers for three hours with a solution of corrosive sublimate in connection with rotation of crops has greatly reduced loss from this disease. Notes are given on the distribution and characteristics of black leg, leaf roll, and mosaic disease of potato. A clover and alfalfa wilt disease due to *Sclerotinia ciborioides*, or *S. trifoliorum*, is briefly described, and two authentic cases of its occurrence in Canada are reported.

In the investigations in economic botany, most of the work has been concerned with the identification of poisonous plants and weeds.

In the report from the field laboratory at St. Catharines, W. A. McCubbin gives observations and experimental results on the more important diseases of fruits and vegetables observed during 1914. Most of the investigations are said to be incomplete and are only briefly described.

Notes on plant diseases of Connecticut, G. P. CLINTON (*Connecticut State Sta. Rpt. 1915, pt. 6, pp. 421-451, pls. 8*).—Notes are given on a number of plant diseases observed during 1914 and 1915, including some previously reported and a number of others not before recorded from the State. Among the latter are white spot of alfalfa; several rots of apples; white tip of carnations; mosaic or white pickle of cucumber; leaf blight, crown gall, and a root rot of mangels; anthracnose of Norway maple; a *Fusarium* rot of onions; two rusts of poplar, one of which is associated with the larch, the other with hemlock; crown gall of privet; and a bacterial leaf spot of soy beans, which is provisionally described as due to *Bacillus* sp.

Report on plant protection, E. SCHAFFNIT and G. LÜSTNER (*Berichte über Pflanzenschutz der Pflanzenschutzstellen. Bonn: P. Rost & Co., 1916, pp. 98, figs. 11*).—This contains the reports of the stations for plant protection at Bonn-Poppelsdorf and Geisenheim for 1913-14 regarding weather and plant injury as related to diseases and animal pests.

Administration report of the government mycologist for 1914-15, W. McRAE (*Rpt. Dept. Agr. Madras, 1914-15, pp. 50, 51*).—It is stated that a coliform bacillus isolated from the soft rotting parts of coconut and palmyra palms attacked by bud rot did not reproduce the rot when injected into the buds of young coconut palms. The results of inoculations of these plants with pure cultures of *Pythium palmivorum* confirmed the experiments of the previous year. Bud rot of coconut palms appears to be widely spread in Malabar, but the damage done is not extensive. Investigation of a new disease of coconut palms on the west coast has been begun.

The use of Bordeaux mixture for the mahali disease of areca nuts, due to *Phytophthora omnivora areca*, is being extended. A fungus (probably an *Ephelis*) on paddy, which transforms the loose panicle into a solid carbonaceous spike, has been brought into pure culture, and a study of the fungus has been begun. A fruit rot of chillies caused by *Vermicularia capsici* is under investigation. A bacterium isolated from black rot of plantain had no effect on young plantain shoots.

*Septoria* on barley, A. G. JOHNSON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 117).—The author notes the occurrence of *Septoria* on a number of varieties of barley at different localities in North and South Dakota and Minnesota. The fungus chiefly attacks the leaf blade, the attacked portion becoming yellowish or yellowish brown and the invaded tissue being killed. The sheaths are less frequently attacked. The fungus is believed to be the same as that known to occur on wheat and to be widely distributed in this country and generally referred to *S. graminum*.

Occurrence of yellow leaf rust of wheat (*Puccinia glumarum*) in the Salt Lake Valley, Utah, P. J. O'GARA (*Science*, n. ser., 44 (1916), No. 1139, pp. 610, 611).—The author describes a rust as having been observed on June 23, 1915, in several wheat fields north and west of Ogden, Utah. Subsequent examination showed the rust to be *P. glumarum*, which has only recently been described as occurring in this country. The infection as noted in the Salt Lake Valley is said to have been rather severe and of considerable economic importance.

*Cordyceps clavicipitis* n. sp., parasitic on ergot, R. ÖRTEGREN (*Svensk Bot. Tidskr.*, 10 (1916), No. 1, pp. 53-58, figs. 3).—The author describes *C. clavicipitis* n. sp., which is claimed to be parasitic on ergot (*Claviceps purpurea*).

Californian thistle rust, A. H. COCKAYNE (*New Zeal. Dept. Agr. Rpt.* 23 (1915), p. 109).—It is stated that a considerable amount of experimentation with Californian thistle rust (*Puccinia suaveolens*) has been carried out, the results of which indicate that this rust may become a valuable instrument in controlling the weed in permanent pastures. The best results are obtained by using material which has been taken from plants recently attacked in preference to that from plants affected the previous year, the latter attaining only a temporary development.

A study on the dry rot disease of maize caused by *Diplodia zeæ*, P. A. VAN DER BIJL (BYL) (*Union So. Africa Dept. Agr. Sci. Bul.* 7 (1916), pp. 60, pls. 15).—This investigation, which was undertaken primarily to test the effect of diseased maize when fed to stock, deals somewhat extensively also with the biology, pathology, and control of the disease of maize caused by *D. zeæ*. The two parts of the paper deal respectively with the fungus in relation to the host and the fungus in the laboratory. Inoculation apparently takes place through the silks but possibly also through the roots. No ear to ear infection was obtained. The spores do not appear to be very resistant.

It is recommended that crop rotation be accompanied by destruction of all diseased material prior to the formation of pycnidia. It is thought that the fungus may fruit naturally on debris other than that of maize in the field. Further experiments are needed regarding the ways in which the disease is spread.

Powdery scab of potato, G. P. CLINTON (*Connecticut State Sta. Rpt.* 1915, pt. 6, pp. 463-469).—On account of the occurrence of the powdery scab of potato in Maine and the possibility of its being introduced into Connecticut, the author, with his assistants, made an inspection of seed potatoes with the result that the powdery scab was found only at three places, in all of which the infection occurred on Maine-grown tubers.

Experiments were conducted to determine the probability of the establishment of this disease in Connecticut, and tubers were planted in clean soil after being treated with formalin alone or with formalin and dusted with sulphur. No powdery scab appeared, and another experiment was undertaken on the supposition that the soil might have become infected. Badly scabbed potatoes were received and planted in a new plat, and potatoes treated as above were planted in the places occupied by the potatoes in the previous experiments. The potatoes when dug showed no powdery scab, even under microscopic examination. The author concludes that this disease is not likely to prove a serious one in Connecticut.

Seed and soil disinfectants for the *Rhizoctonia* disease of potatoes, W. J. MORSE and M. SHAPOVALOV (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 118, 119).—Seed tuber treatment for the control of *Rhizoctonia* disease of potatoes was found more successful with corrosive sublimate than with formaldehyde. The application of sulphur in the soil at the rate of 500 lbs. per acre increased the diseased plants from 20 to 30 per cent.

Potato spraying experiments, third report, G. P. CLINTON (*Connecticut State Sta. Rpt. 1915*, pt. 6, pp. 470-487).—In continuation of a previous report (E. S. R., 25, p. 545), the author gives the results of spraying experiments which have covered a period of 14 years. These experiments were undertaken to determine the value of Bordeaux mixture as a fungicide, to compare the effect of ridged and level culture in preventing rot of tubers, and the value of other fungicides as compared with Bordeaux mixture.

Homemade 4:4:50 Bordeaux mixture gave an average increase of 38 bu. per acre during the 13 years the tests were carried on. Not only did the Bordeaux mixture control blight, but in dry years lessened injury from tip burn and had also possibly a stimulating effect as shown by an average increase of 29 bu. per acre during blight-free years. In all but 4 of 22 tests, the extra cost of spraying was more than covered by the net gain.

In the experiments with ridged *v.* level culture, it was found that ridging and deeper planting tend to lessen rot and blight of potatoes in bad seasons, and in addition, the ridging permits better spraying and easier access to the plants. The total yields of ridged potatoes were as high as those from level culture, the yields of first quality potatoes were greater, and the tubers were less subject to sunburn.

In the comparative test of fungicides, none was found to equal homemade Bordeaux mixture.

A new species of *Melanconium* parasitic on the tomato, W. H. TISDALE (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 116).—On both green and ripe tomatoes in the greenhouse at the Wisconsin Experiment Station, small, dark brown or black spots, seldom more than  $\frac{1}{8}$  in. in diameter, have been observed. From these a fungus was isolated and inoculations were made both through wounds and by spraying unwounded fruit. The characters of the fungus are said to correspond to those of the genus *Melanconium*, although no record of the parasitism of this genus on the tomato has been found.

Infection and resistance studies of *Phytophthora infestans* on the tomato, I. E. MELHUS (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 107).—The author reports tomato foliage as readily infected with *P. infestans* from the Irish potato, but it has not been possible to infect the fruit except through the peduncle, the calyx, or the epidermis when ruptured. The fungus is said to spread more sparingly on the foliage of the tomato than on susceptible varieties of potato. Variations in susceptibility of different varieties of tomato and potato to attack by this fungus are reported.

Second progress report on disease resistance in tobacco, J. JOHNSON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 117).—In continuation of a report on resistance of tobacco to the root rot organism (*Thielavia basicola*) previously noted (E. S. R., 31, p. 448), the author reports encouraging results of selection for resistance in the White Burley variety.

Disinfection to overcome the root rot (*Thielavia basicola*), W. A. BARNET (*Canada Expt. Farms Rpts. 1915*, pp. 1191-1193).—The sterilization of seed beds by means of steam and formalin is described, the steam sterilization proving very satisfactory, while the formalin treatment under the conditions of the experiment was not a success. Treatment with steam for 30 minutes at 100 lbs. pressure is recommended for general practice. Some notes are given on the resistance of varieties of tobacco to root rot infection, and from the author's observations it is thought that by selection and breeding a resistant variety of tobacco can be obtained that will be commercially profitable.

Fire blight investigations, H. A. GOSSARD and R. C. WALTON (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 9, pp. 274-276; *abs. in Phytopathology*, 6 (1916), No. 1, p. 113).—A series of investigations is reported upon in which an effort has been made to determine under what conditions and how long the fire blight organism (*Bacillus amylovorus*) will live in honeydew as it occurs on the leaves, how long it will retain its vitality in the nectaries of other flowers than apple, pear, and quince, and how long it will live in honey.

It was found that the blight organism can live for 7 days in honeydew until the dew is completely dried, and then for at least 3 days longer when moisture is added. In the nectaries of the peach, plum, and cherry blossoms the organism was found to live for 5 days or more and still remain capable of infecting trees. In the experiments with honey, a fresh sample of honey was inoculated with bacteria, and beginning 2 days later inoculations were made on apple shoots for a period of 9 days. In this experiment the maximum life of the organism in honey was found to exceed 72 hours, but from the evidence at hand it is not believed to live longer than 100 hours in this medium.

Longevity of *Bacillus amylovorus*, J. W. HOTSON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 115).—An attempt has been made to determine the length of time the fire blight organism lives in infected branches after they have been cut from the trees.

It was found that the organism existing in branches, when exposed to direct sunlight, remains alive for from 10 to 13 days, and similar results were obtained when the exudate was present on the fruit. When the branches were shaded for part of the day the bacteria remained alive for 27 days in the bark, and when infected branches were left in a field where there was a cover crop of alfalfa, living bacteria were obtained in some cases 29 days after the limbs were cut.

Arsenate of lead as a fungicide for apple scab, W. J. MORSE (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 118).—In a series of spraying experiments covering four seasons, in which the Ben Davis variety of apples was used, satisfactory results are said to have been obtained where arsenate of lead was used alone or in combination with fungicides. The arsenate of lead produced little or no russeting of the fruit, and in three seasons out of four from 12 to 18 per cent more merchantable fruit was obtained than when lime-sulphur was employed.

Irrigation and bitter pit, C. BROOKS and D. F. FISHER (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 111).—Attention is called to the relation between the occurrence of corky bitter pit of apples and an increase in the amount of water used. Heavy irrigation throughout the entire season or medium irrigation until August followed by heavy irrigation resulted in a much greater amount of

bitter pit in case of Grimes Golden, Jonathan, and other varieties than medium or light irrigation throughout the season.

**Blight-resistant roots—the first step toward pear blight control**, A. L. WISKER (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 2, pp. 48-53, fig. 1).—Experience in California with pear blight (*Bacillus amylovorus*) in the past two years is said to have emphasized the inability of orchardists alone to control this disease.

Comparisons are made as to adaptability for stocks of the French or wild European pear (*Pyrus communis*) and the Japan or wild Asiatic pear (*P. sinensis*). The latter is said to make the more vigorous growth, its seedlings are less subject to leaf blight (*Entomosporium maculatum*), its roots have little tendency to sucker, and it resists blight better, on the average, than any other root now in use. It makes vigorous growth with less soil moisture also than does the French pear, and trees grown on Japan root suffer comparatively little also from pear aphid. These and other claims are regarded, however, as somewhat tentative. It is admitted that under conditions of excessive soil saturation the Japan pear may be injured by root rot.

**Further studies on plum wilt**, B. B. HIGGINS (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 117, 118).—In continuation of a previous report (E. S. R., 31, p. 747), the author claims that the fungus causing the plum wilt is a general wound parasite of woody plants but is not found occurring normally on any plant outside of the genus *Prunus*.

**Summer sprays against American gooseberry mildew**, B. T. P. BARKER and A. H. LEES (*Jour. Bd. Agr. [London]*, 22 (1916), No. 12, pp. 1244-1249).—The authors, summarizing the work done by them during the past two years on the summer treatment of American gooseberry mildew, state that their experience agrees with that of Eyre and Salmon (E. S. R., 35, p. 654), as regards the injurious effects of fungicidal concentrations of liver of sulphur as previously used in this connection. Trial has also been made of a combination not known to have been previously tested, consisting of a mixture of liver of sulphur and a soft soap and paraffin emulsion, which is said to have given the most promising results. How far the liver of sulphur furnishes the fungicidal factor is not known, but it is thought that all the ingredients may be required for the full effect. The primary object of this paper is to call this mixture to the attention of other investigators.

It was found that what are called hitting or contact sprays, designed to kill the mycelium and conidia already on the bush, were rendered more or less ineffective by the presence of air between the conidiophores and the conidia. In a series of tests of protective or cover sprays, employing such fungicides as Bordeaux mixture or lime sulphur, no entirely satisfactory results were obtained, as the mildew reappeared, although in slight degree. The cost of treatment and other details are discussed.

**[Fungus diseases of the cranberry]**, H. J. FRANKLIN (*Massachusetts Sta. Bul.* 168 (1916), pp. 1-5).—A report is given of studies carried on on the fungus diseases of cranberries, the work having been done in cooperation with the Bureau of Plant Industry of this Department.

Spraying experiments were conducted with Bordeaux mixture, and the results obtained are similar to those previously reported (E. S. R., 33, p. 350). The sprayed plats yielded less fruit than the untreated checks, although the keeping quality of the sprayed berries was somewhat better than the unsprayed ones. However, berries from plats that had been treated in previous years but not in 1915 showed poorer keeping quality than those which had not been sprayed.

An experiment in controlling fungus diseases by putting copper sulphate in the flowage water was carried out, but the results show no advantage in favor of the treatment. In storage, however, the berries from the treated sections showed smaller percentages of rot than those from other sections.

An investigation of cranberry bogs in New Jersey, where treatment was being made for control of plant diseases, did not reveal any such injury as that caused by spraying tests in Massachusetts. No definite reason for this difference is evident, although it is thought that it may possibly be connected in some way with the use of sand as a mulch in Massachusetts.

The disease known as Wisconsin false blossom is reported on several varieties, and evidence seems to be accumulating that in some way the disease is infectious.

A new disease called blossom end rot in previous reports was more prevalent than usual. The investigation of the fungus causing this disease is being continued.

Eradication on a large scale, E. NELSON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 114).—A description is given of the attempt being made in Florida to eradicate the citrus canker due to *Pseudomonas citri*. The method employed is to destroy with fire the infected trees, these being sprayed with kerosene mixed with crude oil.

Diseases of plants caused by nematodes, G. P. CLINTON (*Connecticut State Sta. Rpt. 1915*, pt. 6, pp. 452-462, pls. 2).—After a brief account of the occurrence and injurious action of *Heterodera radicicola*, the author describes a leaf blight nematode (*Aphelenchus olesistus*) as attacking begonias and ferns in greenhouses.

Cutting out chestnut blighted timber, E. M. STODDARD and A. E. MOSS (*Connecticut State Sta. Rpt. 1915*, pt. 6, pp. 488-496, pls. 2, fig. 1).—In order to determine whether the spread of chestnut blight could be retarded or checked by the removal each year of infected trees, and if so, whether the work is economically possible, the authors carried on experiments on 130 acres, on which every winter all infected chestnut trees were removed, and for comparison the infected trees on an adjoining 190 acres were counted but not removed.

As a result of this investigation, it was found that in Connecticut the cutting and removing from woodlots of trees infected with chestnut blight did not prevent the spread of the disease. The cost of inspection, cutting, and removing is considered too high to warrant its adoption from a commercial standpoint.

A Gloeosporium on horse-chestnut shoots, J. F. ADAMS (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 114, 115).—A blighting of the terminal shoots of the horse-chestnut, due to a species of Gloeosporium, is described. Inoculation experiments with this fungus on apple have produced conditions similar to those produced by *Glomerella cingulata*.

Leaf fall of conifers, F. W. NEGER and J. FUCHS (*Jahrb. Wiss. Bot. [Pringsheim]*, 55 (1915), No. 4, pp. 608-660, figs. 22).—The authors have studied leaf separation and frost killing in certain conifers.

Leaf cast is most commonly due directly to water loss. The forms or processes of separation peculiar to different conifers are described. Frost killing of evergreen foliage appears to be a special case of late frost injury and to have its origin in the untimely awakening of the young needles in spring. The reddening often noted is a post mortem effect having no causal connection with the death of the foliage. It follows exposure to full sunlight of killed needles which still have a high content of water and acid.

Tipburn in white pine, G. P. BURNS (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 116).—A form of tipburn occurring in the forest nursery of the State For-

estry Department of Vermont is reported, in which it appears that the velocity of the wind is the deciding factor in killing the young leaves.

**Eradication of *Cronartium ribicola* from European pine plantings in New York State.** W. H. RANKIN (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 114).—A report is given on the white pine blister rust in plantings of white pine made from seedlings imported from Europe.

## ENTOMOLOGY.

[Report of the] department of entomology, S. B. DOTEN (*Nevada Sta. Rpt. 1915*, pp. 33-41, figs. 5).—A brief summary is given of the work of the year in which the author was assisted by G. G. Schweis.

The conclusion is reached from work with hymenopterous parasites of the codling moth that it is not practical to check the pest by this means.

Reference is made to two papers published during the course of the year relative to a method of photographing living insects.<sup>1</sup>

Two cutworms which are said to have caused considerable injury to alfalfa are the desert cutworm (*Euxoa ridingsiana*) and the variegated cutworm. The former has been found in central and eastern Nevada in the spring feeding in such numbers upon the young shoots of alfalfa that the plant fails to make any growth, while the latter has been found in midsummer injuring the second crop in the same way. The experimental drowning of cutworms is briefly touched upon. Hogs, chickens, and turkeys are shown to consume large numbers of the pest.

With a view to determining the effect of cold and starvation upon the bedbug, 31 were placed in tubes in a box and kept under shelter in the open air from January 21 to April 10, with the result that only 11 remained alive and vigorous. These 11 were alive also on July 1 after having been put in tubes in a tin box, packed in cotton, and stored in a refrigerator at a temperature maintained constantly between 40 and 50° F. A number of bedbugs just hatched from the egg survived after having been kept for nearly three months in cold storage without food. Eggs kept under the same conditions hatched promptly when the temperature was raised. The results of experiments with sulphur fumigation seem to indicate that the eggs of bedbugs are not always killed and that two fumigations, a week apart in warm weather, are necessary to eradicate the pest.

The study of a disease of mature bees which made its appearance in 1915 indicates that it is the so-called Isle of Wight disease, due to *Nosema apis*.

**An attempt to redefine the host relationships exhibited by entomophagous insects.** H. S. SMITH (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 477-486).—The author redefines the old terms now in use with a view to standardizing the terminology of insect parasitism.

**Sprays and spraying.** F. B. PADDOCK (*Texas Sta. Bul. 187* (1916), pp. 5-36, fig. 8).—A brief discussion of the several classes of insects is followed by an extended account of the various insecticides and means for their application. Preventive measures are also considered and a list with addresses is given of manufacturers and dealers in insecticides and spraying machinery.

**Cost of dusting and spraying a New York apple orchard.** C. R. CROSBY (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 375, 376).—The author presents data furnished by W. A. Crandall relative to a 21-acre orchard, containing about 625 trees ranging in age from 35 to 40 years, which was sprayed in 1913 and 1914 and dusted in 1915. Records of the cost of spraying in 1913 and 1914 and of dusting in 1915 presented in tabular form show the spraying to cost about

<sup>1</sup> A "Cold" Flame for Zoological Work (*Camera Craft*, 1914, October); Flashlights of Living Insects (*Camera Craft*, 1915, April).

one-half more than dusting. Reports of extensive observations of the relative efficiency of dusting and spraying by the Cornell Experiment Station have been previously noted (E. S. R., 34, p. 738).

[Work with cranberry insects in 1915], H. J. FRANKLIN (*Massachusetts Sta. Bul. 168 (1916), pp. 31-43*).—In referring to the loss caused by cranberry insects during the year it is stated that that due to the fruit worm was considerably more than in 1913 and 1914 but not as great as in some years. A spanworm (*Abbotana clemataria*), commonly observed on cranberry bogs in July, was reared successfully, the moths emerging between May 20 and 27 from pupæ formed between July 9 and 25 of the previous year. A batch of 432 eggs was deposited by one of the reared moths about May 30, caterpillars emerging therefrom on June 14. Pupation is said to take place at a maximum depth of 2 in. in the sand of breeding cans. While common on the bogs this insect has not appeared in sufficient numbers to do any considerable injury.

An ichneumonid parasite (*Amblyteles putus*) was reared during the year in small numbers from the green spanworm (*Cymatophora sulphurea*), commonly found late in May eating holes in the winter buds at the tips of the uprights. An infestation by what appeared to be the cranberry rootworm (*Rhabdopterus picipes*) was discovered in October on a bog at Wareham, some two acres having shown more or less injury. In an examination of a bog in South Carver it was found that a small beetle (*Cryptoccephalus incertus*), present in great numbers, was devouring the foliage. It is pointed out that there are four ways in which a bog may become infested with the gipsy moth.

Records of the amount of the cranberry tip worm (*Cecidomyia oxycoccana*) injury on 14 different bogs in 1914-15 and the effect of resanding are presented in tabular form. There was not a single bog, a record of the 1914 examination of which was kept, that after being resanded did not show a tremendous drop in the amount of tip worm infestation. On the other hand, practically only one bog that had not been resanded between September, 1914, and May, 1915, failed to show an infestation equal to or greater than that of 1914.

No advantage was obtained from the sweetening of arsenical sprays with saccharine in use against the black-head fire worm (*Rhopobota vacciniana*). A heavy infestation by this pest on a bog at Wareham was greatly reduced by the holding of a partial flowage until the first of July.

In experimental work with the cranberry fruit worm (*Mincola vaccinii*), two netting sacks, each containing 160 cocoons, were submerged in a pond in 3 ft. of water on January 15. One of the sacks which was taken from the water on March 31 showed 40 per cent of the worms therein to be alive, almost a quarter of them being quite active. Those in the second sack which was removed from the water on May 20 were all found dead and most of them more or less decomposed. The percentage of parasitism of this pest was considerably higher than that of the previous year. Parasitism by *Phanerotoma tibialis* ranged from 27 to 72 per cent on dry bogs and from almost none to about 22 per cent on bogs that had the winter flowage held late. Parasitism by *Pristomeridia agilis* ranged from 5 to about 38 per cent in fruit worms taken from dry bogs and from none to about 7.5 in those from bogs that had the winter flowage held late. The eggs of the fruit worm showed a range in parasitism by *Trichogramma minuta* from 42 to about 89 per cent on dry bogs and from about 12 to 89 per cent on those with winter flowage. It is estimated that the predacious and parasitic enemies of the fruit worm destroy not less than 97 per cent on some dry bogs and close to 90 per cent on some flowed bogs.

**Gonepteryx rhamni** and *Castnia therapon* in New Jersey, H. B. WEISS (*Jour. Econ. Ent., 9 (1916), No. 3, p. 378*).—An almost perfect female of *G. rhamni*, known as the brimstone butterfly, was taken from a case of French

shrubs at Rutherford, N. J., having apparently emerged en route. A larva of the lepidopteran *C. tharapon* was found in a greenhouse at Bound Brook, N. J., infesting orchids which originally came from Pernambuco.

Grasshopper control, D. E. MERRILL (*New Mexico Sta. Bul. 102 (1916), pp. 32, figs. 19*).—This is a discussion of the grasshopper problem in New Mexico, in every part of which State damage is liable to take place. Mention is made of seven species as sources of injury, namely, *Melanoplus differentialis*, *M. bivittatus*, *M. atlantis*, *M. femur-rubrum*, *Hadrotettix trifasciatus*, *Schistocerca venusta*, and *Brachystola magna*, of which the first three are the most important. The greatest injury is caused to alfalfa, garden and truck crops, grains, and young fruit trees.

Their control is deemed practicable through the destruction of breeding places and eggs and of the grasshoppers by poisoning or by capture with machines for that purpose.

Notes on *Anasa andresii*, an enemy of cucurbits, T. H. JONES (*Jour. Econ. Ent., 9 (1916), No. 4, pp. 431-434*).—Preliminary notes on the biology of *A. andresii*, based on observations made by the author and C. E. Smith at Baton Rouge, La., during 1915, are presented. The species is also known to occur in Florida, Texas, New Mexico, central Mexico, and Cuba. Its injury is similar to that caused by *A. tristis*.

Triphleps insidiosus as the probable transmitter of corn-ear rot (*Diplodia* sp., *Fusarium* sp.), J. A. HYSLOP (*Jour. Econ. Ent., 9 (1916), No. 4, pp. 435-438*).—A report of observations made at New Paris, Me., in the fall of 1912. The form of ear rot caused by *Bacterium stevarti* was a source of severe injury to sweet corn in the large corn-canning districts of the State.

Some unpublished notes on *Pemphigus betæ*, A. C. MAXSON (*Jour. Econ. Ent., 9 (1916), No. 5, pp. 500-504*).—This is a report of observations on the biology of the sugar beet root louse at Longmont, Colo., by the author, conducted in cooperation with the Colorado Experiment Station.

Dispersion of scale insects by the wind, H. J. QUAYLE (*Jour. Econ. Ent., 9 (1916), No. 5, pp. 486-493, fig. 1*).—In work at the Citrus Substation at Riverside, Cal., the author found young black scales to be carried by the wind as far as 450 feet, the greatest distance at which tanglefoot sheets were set. The young of the red scale were captured on such sheets at distances ranging from 30 to 150 feet.

Reducing the cost of commercial spraying, R. S. WOGLUM (*Jour. Econ. Ent., 9 (1916), No. 4, pp. 392-395, fig. 1*).—The author describes and presents a diagram of a pipe system in a 10-acre orange orchard in southern California, in which the cost of applications of water under high pressure for the control of mealy bugs was found to average 75 per cent less than where the work was done by means of a portable sprayer alone.

The white-marked tussock moth (*Hemerocampa leucostigma*), H. C. YINGLING (*Mo. Bul. Ohio Sta., 1 (1916), No. 9, pp. 265-270, figs. 3*).—A popular account of this moth, which is one of the most important insect enemies of shade and ornamental trees in many cities in Ohio.

The New Mexico range caterpillar and its control, V. L. WILDERMUTH and D. J. CAFFREY (*U. S. Dept. Agr. Bul. 443 (1916), pp. 12, figs. 12*).—This is a report of work with *Hemileuca olivæ* commenced at Koehler, N. Mex., in 1913, and carried on in continuation of that by Ainslie, as previously noted (*E. S. R., 23, p. 463*). Its life history and natural enemies have been given particular attention.

The pest is said to be of economic importance only in the five counties in the northeastern corner of the State, but a scattering infestation occurs across

the line in Texas and two colonies were found during 1915 in southern New Mexico. Many cultivated crops are now attacked in addition to range grasses. The authors conclude that its present destructive abundance is due to the reduction in numbers of its natural enemies through some severe climatic condition.

The introduction of natural enemies appears to be the only practical measure in control work on the range. As a result of this work a number of insect enemies of the pest appear to have become established. The native natural enemies also are now beginning to assert themselves again.

The small pink corn worm (*Batrachedra rileyi*) in Mississippi, R. W. HARNED (*Jour. Econ. Ent.*, 9 (1916), No. 2, pp. 295-298, figs. 2).—This pest, an account of which by Chittenden has been previously noted (*E. S. R.*, 35, p. 256), attracted more attention during the previous 14 months than any other occurring in Mississippi. During November and December, 1914, hundreds of complaints in regard to the work of this insect in stored corn were received, most of which came from the central part of the State.

Control of the variegated cutworm in Ventura County, California, G. E. BENSEL (*Jour. Econ. Ent.*, 9 (1916), No. 2, pp. 303-306, pls. 3).—The variegated cutworm is widely distributed in Ventura County, Cal., where it has done considerable damage to the sugar beet crop since April, 1913, when the first serious outbreak occurred. The methods of control mentioned include application of arsenicals, ditching, and trapping the moths by lights.

A coccid-feeding moth, (*Blastobasis*) *Holcocera iceryælla*, E. O. ESSIG (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 369, 370, pl. 1).—In addition to the black scale and cottony cushion scale recorded by Riley as hosts of this moth, the author has found the European peach scale (*Lecanium persicæ*), the greedy scale (*Aspidiotus camellia*), and Baker's mealy bug (*Pseudococcus bakeri*) to serve as hosts at Berkeley, Cal.

Additional notes on the use of dust sprays against the corn-ear worm, J. W. MCCOLLOCH (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 395-398).—Further work by the author (*E. S. R.*, 34, p. 63) has led to the following conclusions:

"The percentage of corn-ear worm and mold injury decreases as the number of dustings are increased. The cost of dusting is prohibitive where corn is grown for grain or forage but is practical where corn is raised for roasting ears, show purposes, or for seed corn. Sulphur is superior to flour or lime as a carrier for arsenate of lead and there is some indication that it also serves as a fungicide. Fifty per cent arsenate of lead does not control the corn-ear worm so effectively as does 75 per cent arsenate of lead."

*Bucculatrix thurberiella*, a pest of cotton in the Imperial Valley, E. A. MCGREGOR (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 505-510, pls. 2).—The larvæ of this tineid moth were found in June, 1916, devouring the leaves of cotton in fields in eight localities in the Imperial Valley, Cal., indicating that it occurs in every cultivated part of the valley. It was found in every cotton field examined and in some fields every leaf was attacked by it.

Economic Syrphidæ in California, W. M. DAVIDSON (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 454-457).—A brief discussion of the syrphus flies of economic importance in California.

Dispersion of *Musca domestica* under city conditions in Montana, R. R. PARKER (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 325-354, pls. 4).—This is a detailed report of dispersion studies carried on in Miles City, Mont., during the season of 1915. In that city, the built-up portion of which is about 1.5 miles square, 387,877 marked flies were liberated from four release points. Of these a total of 1,056 were recaptured at 78 stations which varied from 50 to 3,500

yds. from the point of release, the latter being the greatest distance at which recaptures were attempted.

"The full possibilities of dispersion were not determined, due to the relatively small size of the city, but the fact that flies spread from release points on one border to points on the opposite side indicates a possible radius of 2,333 yds. (1½ miles), and that flies even traversed the entire city and crossed open country to points beyond justifies the belief in a still greater radius. The actual territory over which flies were recovered in the city was about 2 square miles, but possible dispersion over a territory of from 5 to more than 12 square miles was indicated."

A bibliography of 11 titles is appended.

Some observations on the breeding habits of the common house fly (*Musca domestica*), A. T. EVANS (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 354-362, pls. 3).—The author reports experiments carried on during the summer of 1915. With a single exception, no larvæ of the house fly were found breeding in garbage.

Sarcophagidæ of New England: Genus *Sarcophaga*, R. R. PARKER (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 438-441, fig. 1).—A new species, the occurrence of which in abundance was limited to the presence of larvæ of either the gipsy moth or forest tent caterpillar, especially the latter, is described as *Sarcophaga aldrichi*. The status of this species in the economy of nature remains to be determined.

Notes on *Pegomya hyoscyami*, E. N. CORY (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 372-375, fig. 1).—The author reared this dipterous leaf miner from lamb's quarters (*Chenopodium album*), spinach (*Spinacia oleracea*), and pigweed (*Amarantus retroflexus*) in Maryland, and presents observations on its biology. The parasite *Opius foxcolatus* was reared from nearly every lot of miners. Studies of this insect by Cameron in England have been previously noted (E. S. R., 32, p. 351).

The columbine leaf miner, E. N. CORY (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 419-424, pl. 1, figs. 2).—A report of biological studies at the Maryland Experiment Station of *Phytomyza aquilegiæ*, which mines the leaves of *Aquilegia* spp.

Injury to peanuts by the twelve-spotted cucumber beetle (*Diabrotica 12-punctata*), D. E. FINK (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 366-368, pl. 1).—The author has found that peanut pods, particularly when still young and soft, are subject to serious injury by the larva of this beetle. Rotation and vigorous growing crops are decided factors in controlling or keeping the crop free from attack by this pest.

*Lachnosterna* larvæ as a possible food supply, L. O. HOWARD (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 389-392).

A note on the predacious habits of *Dineutes* ("whirligig beetles") toward *Anopheles* larvæ, R. C. DERIVAUX (*Pub. Health Rpts. [U. S.]*, 31 (1916), No. 20, pp. 1228-1230).—The author's observations have led to the inference that, while capable of swift destruction of *Anopheles* larvæ under experimental conditions and in the absence of protecting vegetation and flottage, *Dineutes* alone are not of sufficient efficacy as natural enemies to justify considering waters inhabited by them as free of dangerous potentialities as *Anopheles* breeding places. "Under natural conditions, their influence on *Anopheles* propagation is of but small practical importance."

The eggplant tortoise beetle, T. H. JONES (*U. S. Dept. Agr. Bul.* 422 (1916), pp. 8, figs. 3).—In the spring of 1915 the larvæ of *Cassida pallidula* were a source of injury to the foliage of eggplant and Irish potatoes at Baton Rouge, La. During that year studies were made of its biology and experiments con-

ducted with insecticides. Various wild solanums also serve as food plants for the species, which is quite widely distributed over the more southern portions of the United States.

In the laboratory over 200 eggs were deposited by a single female, 12 being laid in one day. They are largely placed upon the underside of the leaves but may be found on other parts of the plant. In June a period of from 4 to 5 days was required for their incubation. The five larval instars of 43 individuals observed required from 12 to 20 days for development during June and July. During these months the pupal period occupied from 2 to 7 days. The winter is passed in the adult stage. It is pointed out that under favorable conditions five generations may develop during the year at Baton Rouge.

Experiments with lead arsenate and zinc arsenite indicate that the pest can be kept under control through the use of arsenicals.

The fruit-tree leaf *Syneta*, spraying data, and biological notes, G. F. MOZNETTE (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 458-461, pls. 2).—*Syneta albida* is said to have been the source of considerable injury to prunes and cherries in the Willamette Valley of Oregon in the spring of 1916.

The reflex "bleeding" of the coccinellid beetle, *Epilachna borealis*, N. E. McINDOO (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 2, pp. 201-223, figs. 21).

Notes on the habits of a dangerous genus of weevils, W. D. PIERCE (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 424-431, figs. 4).—This paper deals with weevils of the genus *Polydrusus*. Two European species have recently been found in the United States and four other species are apparently native or have been long established in this country.

The imported poplar root weevil (*P. impressifrons*) is already doing considerable damage in New York and Connecticut. The author gives descriptions of its several stages and includes notes by Parrott on its habits in New York State. The imported fruit-bud weevil (*P. sericeus*), two specimens of which have been collected in Marion County, Ind., is in Italy quite injurious as an adult to the buds and foliage of fruit trees, especially the pear.

*Sporotrichum globuliferum*, a natural enemy of the alfalfa weevil, L. P. ROCKWOOD (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 493-499).—This entomogenous fungus is said to develop spontaneously as an infectious disease of the alfalfa weevil on the bench lands of the Salt Lake Valley, in the early spring. Laboratory experiments are reported.

Report from the division of bees for the fiscal year ended March 31, 1915, F. W. L. SLADEN ET AL. (*Canada Expt. Farms Rpts. 1915*, pp. 991-1014, pls. 3).—The work of the year at the Central Experimental Farm at Ottawa and at the branch stations is first reported upon in a general way by the apiarist, F. W. L. Sladen (pp. 993-996), who touches upon a number of problems that confront the beekeeper in Canada. It has been demonstrated that bees can be kept at all of the farms and stations, though losses of bees, sometimes heavy, have occurred during the winter. A considerable measure of success has been met with in the wintering of bees outdoors at Ottawa in cases packed with insulating material and sheltered from the wind. Attempts at wintering in this manner at several of the stations are said to warrant a further trial. Investigation has shown, with the possible exception of the farms on the prairie and in the dry belt of British Columbia, that the bulk of the surplus honey is generally gathered from less than one-half dozen species of plants and in some cases from only two or three, the quality of the honey from these plants being excellent. A change to Italian bees in 1910 at the Central Farm, in order to control the European foul brood, resulted not only in the suppression of the disease but in a substantial increase of the honey crop.

The report of the apiarist of the Central Farm (pp. 997-1000) summarizes the wintering results of 1913-14 and 1914-15, reports upon the honey crop of 1914, and describes the type of hive used. Thirty-seven colonies placed in a cellar on November 10, 1913, averaged a loss in weight of 14.4 lbs., the greatest loss being 27 lbs., and with the 16 colonies protected outdoors the average weight loss was 22.5 lbs. and the greatest loss 35 lbs. In 1913-14 the last good flight before winter was on November 22, at a temperature of 63°, and the first extensive spring flight was on March 16, at a temperature of 50°. In 1914-15 the last flight before winter occurred on November 26, at a temperature of 45°, and the first spring flight was on March 23, at a temperature of 45.5°. The total honey crop in 1914 was 2,348 lbs. of extracted honey and 69 sections of comb honey. The extracted honey consisted of 120 lbs. of dandelion honey gathered in May, 1,675 lbs. of white honey gathered during June and July, and 553 lbs. of amber-colored honey gathered at the end of July and in August. The largest yield from a single colony was 257 lbs. of extracted honey, from a colony that had wintered outside. A table is given which shows the average loss or gain in weight of a colony during successive periods of about ten days during the season, with the principal sources from which the honey was gathered. Experience has shown that the 8-frame brood chamber does not supply sufficient breeding space, but that a 10-frame brood chamber is usually large enough to accommodate all, or nearly all, of the brood.

Reports of the superintendents on the bee work at the experimental farms follow (pp. 1001-1014).

Detection of arsenic in bees, E. B. HOLLAND (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 364-366).—A preliminary report of work at the Massachusetts Experiment Station, in which 12 out of 23 samples of affected bees were found to contain a small amount of arsenic.

Professor Gossard's theory on fire blight transmission, E. F. PHILLIPS (*Jour. Econ. Ent.*, 9 (1916), No. 3, pp. 362, 363).—In reviewing the paper by Gossard previously noted (*E. S. R.*, 35, p. 662), the author calls attention to the lack of experimental data supporting the view that *Bacillus amylovorus* is transmitted by the honeybee.

The chrysanthemum gall fly, *Diarthronomyia hypogæa*, E. O. ESSIG (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 461-468, pls. 2, figs. 3).—In a general survey of the central part of the State, made by the author, this gall fly was found quite abundant and destructive in the region of San Francisco Bay, where it has been known to flourish for over 15 years. It causes cone-shaped galls on the leaves, leaf-petioles, stems, and buds. Infested shoots are often distorted and are eventually killed. The growing of the crop under cloth is the most efficient and satisfactory means for preventing this injury.

A new species of *Isosoma* attacking wheat in Utah, R. W. DOANE (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 398-401, pl. 1, fig. 1).—During the course of investigations conducted in the so-called dry farm regions in the Salt Lake Valley, the author collected two species of *Isosoma*. One of these was the well-known wheat straw worm (*I. grande*), the other a new species, here described as *I. vaginicum*, which he terms the wheat sheath worm, as the larvæ confine their attacks to the leaf sheath. The swelling and hardening of the walls of the sheath which results from their attack presses on the stem in such a way as to prevent the sap from flowing through it readily, and the plants become stunted and produce only small, poorly developed heads. Some fields observed were so badly injured that they were not considered worth harvesting, and the whole crop was a total loss. This new species has been found only in the dry farm region.

Descriptions of and observations on some chalcidoid Hymenoptera, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 7, pp. 242-246).

An egg parasite of the army worm (*Heliophila unipuncta*), W. P. FLINT (*Jour. Econ. Ent.*, 9 (1916), No. 3, p. 377).—A chalcidid parasite reared from the eggs of the army worm in the vicinity of Springfield, Ill., has been determined to be a species of *Telenomus*.

Notes on *Rhogas terminalis*, W. E. PENNINGTON (*Jour. Econ. Ent.*, 9 (1916), No. 4, pp. 401-406, pl. 1, fig. 1).—This paper deals with observations on *R. terminalis*, a braconid parasite of the army worm, made at Hagerstown, Md.

In that region there appear to be four complete generations annually, with a possibility of a maximum of six generations. The parasite is present throughout the entire active season of its host and hibernates in the puparium stage. It oviposits only in second and third instar host larvae.

Breeding fruit fly parasites in the Hawaiian Islands, J. G. BRIDWELL (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 472-477).—This reports upon breeding work in Hawaii with introduced parasites.

Municipal control of the Argentine ant, E. R. DE ONG (*Jour. Econ. Ent.*, 9 (1916), No. 5, pp. 468-472).—This ant, first recognized in California in 1908 at only eight points, has since spread to most of the larger cities on the coast. In the present paper the author describes the control measures made use of.

### FOODS—HUMAN NUTRITION.

The vegetarian diet in the light of our present knowledge of nutrition, E. V. MCCOLLUM, N. SIMMONDS, and W. PITZ (*Amer. Jour. Physiol.*, 41 (1916), No. 3, pp. 333-360, pl. 1, figs. 19).—This article discusses the vegetarian diet in the light of extensive experiments carried out at the Wisconsin Experiment Station, in which restricted diets have been fed to several species of laboratory and other animals.

Attention is called to the fact that little confidence can be placed on the results of human experience with vegetarian diets because of the frequent consumption of foods prepared with milk, eggs, and butter, and the use of soups, gravies, etc., which include extracts of fats of animal origin. Although experience shows that grazing animals grow from a comparatively early age if fed entirely on food derived from plants, the authors state that they have not found "convincing evidence that any mammal has been adequately nourished from weaning time by a mixture of the seeds of plants and has made the maximum amount of growth and at the maximum possible rate."

The results of work by other investigators on the adequacy of a vegetarian diet for growth and maintenance are reviewed, and the authors reproduce a number of charts from their own experiments showing the growth of laboratory animals (rats) when fed upon different vegetarian diets.

Reference is made to earlier work by the senior author and others, in which the fact was established that, in addition to purified protein, carbohydrate, fat, and salt mixtures, there must be supplied two dietary factors whose chemical natures are at present unknown. These factors are referred to as fat-soluble A and water-soluble B, rather than denoted by the indefinite term "vitamin."

With reference to polyneuritis in pigeons, induced by diets of polished rice or purified foodstuffs, the authors state that they are convinced that "all the observed pathological phenomena can be accounted for in maladjustments relating to the following factors: The inorganic constituents; poor quality and inadequate quantity of the protein content; shortage of the substances A or B, or of both of them, and in certain cases the presence of toxic constituents in

the natural foodstuffs. The latter may be of either inorganic or organic nature. Aluminum and colloidal silica in the one class have been suggested and gossypol of the cottonseed, and the toxic effect of the oil of the wheat kernel which . . . [were] recently described may be cited as examples of the second."

Methods of experimentation, which enable the isolation of individual dietary factors and the evaluation of the individual dietary components in any natural foodstuff, have been described in the present and former papers. They have shown how the degree in which the shortcomings of one natural foodstuff are corrected by the supplementary character of another can be studied by biological methods sufficiently sensitive to yield results of great practical value.

The authors state that the "practically complete success in the nutrition of rats with strictly vegetarian diets made up of but three natural foodstuffs, and the failure attending the employment of a wider variety in the food mixture, emphasizes the fallacy of the assumption that the safest plan to insure perfect nutrition is to include a wide variety in the selection of the constituents of the diet. So long as definite knowledge is wanting concerning the specific nutritive properties of the constituents of the diet, variety will unquestionably make for safety, but will not by any means assure safety, and indeed can scarcely secure the optimum result in any considerable percentage of cases." As soon as an adequate knowledge of the specific properties of the natural foodstuffs and their supplementary relations to each other is possessed, it will be possible to compound fairly simple and monotonous diets which can be depended upon to induce physiological well-being closely approximating the optimum.

"The conscientious adherence to a vegetarian diet by one who has no adequate technical knowledge regarding the subject of diet appears to be fraught with danger, since among the foods of vegetable origin ordinarily consumed by human beings several dietary factors are as a rule of an unsatisfactory chemical character. It is certain that all of the components of a successful diet are present in foods of plant origin."

**The distribution in plants of the fat-soluble A, the dietary essential of butter fat, E. V. McCOLLUM, N. SIMMONDS, and W. PRITZ (*Amer. Jour. Physiol.*, 41 (1916), No. 3, pp. 361-375, pl. 1, figs. 11).**—To determine whether the indispensable dietary factor, fat-soluble A, is present in foods of vegetable origin or is a specific product of the mammary gland and the ovary of birds, various types of substances of plant origin were fed with rations made up so as to be wholly adequate when one of the growth-promoting foods was included but inadequate when such foods were omitted. Records are given of the growth of laboratory animals (rats), which were fed upon rations in which maize, cottonseed, linseed, olive, sunflower-seed, and soy-bean oils, respectively, were the only source of the dietary factor contained in butter fat. The results of these experiments showed that the fat-soluble A is not found in fats and oils of plant origin.

Rats consuming cotton-seed oil prepared by ether extraction suffered intoxication within a few weeks and showed rapid loss of weight, but the commercial bleached oil, prepared by hot pressing, could be fed at the same plane of intake with no signs of injury. This corroborates the observations of other investigators that the toxic factor "gossypol" is soluble in ether and is present in the fat prepared by the use of this solvent. By feeding rations which made it possible to test for toxicity of low intensity, the authors found that wheat oil, linseed oil, and hydrogenated cotton-seed oil showed definite but not severe toxic effects on young rats.

It was observed in the experiments here reported that "ether extraction of plant tissue does not remove the substance essential for growth which is contained in butter fat. The obvious working hypothesis must for the present

assume that the fat-soluble A is in chemical union in the plant tissues and in a complex which is not soluble in fat or in ether. In digestion and absorption it is set free and, being readily soluble in fats, thereafter accompanies the fats in the animal body."

The relation of the unidentified dietary factors, the fat-soluble A and water-soluble B, of the diet to the growth-promoting properties of milk, E. V. McCOLLUM, N. SIMMONDS, and W. FITZ (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 33-43, figs. 6).—Experiments with laboratory animals (rats) were carried out to determine the ability of normal female rats to nourish their young when confined to a diet known to be adequate for growth when satisfactory amounts of the dietary essentials, fat-soluble A and water-soluble B, are added, and inadequate for growth when either of these factors is omitted.

Female rats were fed a ration of natural foodstuffs until their young were delivered. The litter in all cases was reduced to four and several series of experiments conducted in which the basal ration consisted of purified casein, dextrin, inorganic salts, and agar-agar. This was adequate for growth except for the absence of the dietary factors, fat-soluble A and water-soluble B. In a second series of experiments butter fat containing fat-soluble A was added to the basal ration. In another, water-soluble B was added in the form of an alcoholic extract of wheat embryo, and in still another series both fat-soluble A and water-soluble B were added. Charts are given which show the rate of growth of the young animals and the weight of the nursing mothers receiving these rations.

It is concluded from these experiments that these two constituents of the diet (fat-soluble A and water-soluble B) "pass into the milk only as they are present in the diet of the mother, and that milks may vary in their growth-promoting power when the diets of the lactating animals differ widely in their satisfactoriness for the growth of young. . . .

"The chemical natures of the fat-soluble A and water-soluble B, whether these represent in each case a single substance or a group of substances, are of such a character that they can not be formed within the animal body from any of the cleavage products of proteins."

Studies on experimental scurvy in guinea pigs, LEILA JACKSON and J. J. MOORE (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 478-510, figs. 14).—These experiments were undertaken as the result of a disease noted among the laboratory guinea pigs maintained upon a diet which, in addition to oats, green vegetables, hay, and water, consisted largely of milk from a cow having experimental streptococcal mastitis. To determine the factors in the diet responsible for the disease, groups of the laboratory animals were fed upon various combinations of food. The diets tested included commercially pasteurized market milk; raw milk; boiled milk; milk and streptococcus broth; streptococcus broth; water and hay; carrots, cabbage, and hay; milk, vegetables, and oats; skim milk; cream; milk and olive oil; lactose water and hay; limewater; casein and hay; condensed milk; thyroid extract, milk, and hay; hay and oats, bread, or bran; milk and oats; and goat's milk. The results of the investigation are summarized in part as follows:

"Experimental scurvy was produced in guinea pigs by diets of pasteurized, raw, boiled, skimmed, and condensed milk, streptococcus broth and milk, milk and green vegetables, thyroid extract and milk, casein and water, oats, bread, and bran. The addition of calcium lactate to milk or the injection of calcium lactate into guinea pigs on a milk diet did not prevent scurvy. A cream diet, and a diet of olive oil added to milk, produced a 'fat constipation' with early death. Daily injections of olive oil into animals on a milk diet had no anti-scorbutic effect.

"Mixed broth cultures of *Streptococcus viridans* and *Streptococcus hemolyticus*, water, lactose water, and limewater did not produce scurvy. In a series of six guinea pigs fed on goat's milk for over 40 days, no symptoms of scurvy developed. . . .

"The average time for the onset of symptoms with pasteurized milk was 19 days. With other milk diets this varied from 11 to 19 days. The earliest lesion was observed on the tenth, the latest on the twenty-ninth day."

The lesions produced by the disease, as shown by histological examination of post-mortem material, are described in detail.

The salicylic acid reaction of beans, H. C. BRILL (*Philippine Jour. Sci., Sect. A, 11 (1916), No. 2, pp. 81-89*).—This article summarizes information regarding the nutritive value of different sorts of beans.

Tests were made of a number of samples of Philippine, Japanese, Chinese, and American beans and several breakfast foods and coffee substitutes to determine their reaction to the ferric chlorid test for salicylic acid. The soy beans were found to give the ferric chlorid test for salicylic acid and the negative test for salicylic acid with Jorissen's reagent and with Millon's reagent.

Canned sea urchin, F. T. SHUTT (*Canada Expt. Farms Rpts. 1915, pp. 149, 150*).—Analyses were made of canned sea urchin prepared for food purposes. The composition of the material was as follows: Water, 66.64 per cent; albuminoids, 12.01 per cent; fat or oil, 12.88 per cent; and ash, 1.09 per cent.

1001 tests of foods, beverages, and toilet accessories, good and otherwise, H. W. WILEY and ANNE L. PIERCE (*New York: Hearst's International Library Co., 1916, rev. ed., pp. XXVIII+344, pl. 1*).—The earlier edition of this work has been noted (E. S. R., 32, p. 162).

[South Dakota food and drug law] (*Vermilion, S. Dak.: State, 1916, pp. 15*).—The text of the South Dakota law and the opinion of the Attorney General relative to it are given, together with rules and regulations issued under the law.

Report of the dairy and food commissioner for the year 1914, B. L. PURCELL (*Ann. Rpt. Dairy and Food Comr. Va. [7] (1914-15), pp. 64*).—The results are reported of the inspection of dairies, slaughterhouses, groceries, hotels, restaurants, etc., and data are given regarding 660 samples of food and feeding stuffs, of which 121 were found to be in violation of law.

Annual report of the dairy and food commissioner of Virginia, B. L. PURCELL (*Ann. Rpt. Dairy and Food Comr. Va. [8] (1915-16), pp. 20+50+63+55+63*).—This publication consists of four quarterly reports covering the period from March 1, 1915, to March 1, 1916. It reviews the work done by the dairy and food division of the state department of agriculture, which included the sanitary inspection of restaurants, lunch rooms, grocery stores, dairies, etc. Examinations and analyses of samples of food, feeding stuffs, etc., were made.

Storage, handling, and sale of food in Philadelphia, JANICE S. R. LIT (*Rpt. Henry Phipps Inst. [Univ. Penn.], 12 (1916), pp. 9-55, pls. 10, figs. 11*).—This is a report of a study undertaken to obtain an idea of conditions existing in the city. During 1915 over 1,000 stores (including groceries, bakeries, meat shops, fish markets, creameries, ice-cream and confectionery stores, and produce establishments) and about 200 pushcarts and street stands were examined and scored on various factors, such as sanitary conditions of the surroundings, type and number of workers, protection of food against contamination, grade of food handled, storage of food, etc. The districts chosen were considered to be representative of various sections of the city.

Many of the places where food was sold were in poor repair, and in many instances toilets and washing facilities were not provided. Evidences of expectoration were prevalent in the main storerooms in about 40 per cent of the

places investigated. One of the worst conditions noted was the lack of screening or other means of protecting the food from domestic animals and flies and from handling by prospective buyers. Fruit, cakes, pies, bread, candy, and meats were very frequently exposed to such contamination. Conditions in municipal markets were found to be generally worse than in the stores, the sanitary condition of the sheds being bad and practically all of the foods exposed. As a result of the study, legislation and changes in the organization of the city health department were recommended. The publication contains several illustrations, maps, and tables, which present the results of the investigation.

Food inspection service in Philadelphia (*Rpt. Henry Phipps Inst. [Univ. Penn.], 12 (1916), pp. 57-94, figs. 13*).—This report describes and criticizes the food-inspection service of the city and recommends means for overcoming its limitations and objectionable features. It is based upon the study reported above.

A photographic method for measuring the surface area of the (human) body, F. G. BENEDICT (*Amer. Jour. Physiol., 41 (1916), No. 3, pp. 275-291, figs. 5*).—A method is described which establishes a relationship between the area of the body as computed from photographic views of certain definite poses of the nude figure (particularly a side view with arm extended) and the area as actually determined by the linear formula of DuBois (*E. S. R., 35, p. 370*).

"Comparisons between the photographed areas and the body surface as computed from the DuBois linear formula show, even with the most diverse configurations of body, a constancy rarely observed in anatomical measurements or in computed ratios based upon such measurements."

The relationship between body surface and heat production especially during prolonged fasting, F. G. BENEDICT (*Amer. Jour. Physiol., 41 (1916), No. 3, pp. 292-308*).—A historical review is given of the development of the idea of proportionality between the area of the body surface and heat production. Employing the photographic method described in the above article, the body area of the subject of a 31-day fasting experiment (*E. S. R., 33, p. 566*) and the heat production per square meter of body surface were recomputed.

"The values obtained showed a decrease similar to that previously found. The decrease in the heat production per square meter of body surface amounted to 28 per cent, a decrease that can be interpreted only as proof of the inapplicability of the surface area law to subjects with widely varying states of nutrition. This shows it to be impossible to compare a standard value obtained with a large number of robust, normal individuals with that obtained with emaciated diabetics, and thus supplies strong proof of the legitimacy and practicability of the group system of comparing pathological cases with normal individuals of like height and weight, i. e., of general anatomical and morphological similarity."

The effects of exposure to cold upon experimental infection of the respiratory tract, J. A. MILLER and W. C. NOBLE (*Jour. Expt. Med., 24 (1916), No. 3, pp. 223-232*).—The experiments here reported are part of a series carried out by the New York State Ventilation Commission to determine the physiological effect of low temperatures. Laboratory animals (rabbits), after being subject to sudden changes of temperature from hot to cold and cold to hot, were inoculated by spraying the mucous membranes of the nose and throat with a live culture of *Bacillus bovisepiticus*, an organism pathogenic to rabbits. The following conclusions are drawn from these experiments.

"Respiratory infection of rabbits with *B. bovisepiticus* (snuffles) is favored by chilling the animals after they have been accustomed to heat.

"The character of this disease, which occurs frequently in rabbits under natural conditions, makes the application of the experimental results to similar

respiratory conditions in man less open to objection than in similar experiments with other infections.

"The weight of experimental evidence, including . . . [that of the authors], does not justify the elimination of exposure to cold as a possible though secondary factor in the incidence of acute respiratory disease.

"From the limited data of . . . [the] last two experiments it is suggested that any marked change of temperature predisposes rabbits to this infection, the severity of which varies with the amount of change, and that a change from low to high temperature has an even more marked effect than that from high to low."

### ANIMAL PRODUCTION.

The relative value of field roots, F. T. SHUTT (*Canada Expt. Farms Rpts. 1915, pp. 150-155*).—Analyses are given of 24 varieties of mangels, 30 varieties of turnips, and 8 varieties of carrots.

It appears that while the character of the season has much to do with the relative richness of mangels, heredity also plays an important part in this direction. There were many instances in which the turnips closely approached or equaled mangels in dry matter content, but they were decidedly inferior to mangels as regards sugar. Carrots were not markedly different from turnips in their percentage of dry matter, but were much richer in sugar.

Fodders and feeding stuffs, F. T. SHUTT (*Canada Expt. Farms Rpts. 1915, pp. 127-149*).—Analyses are given of the following feeding stuffs: Oats, barley, bran, shorts, ground corn, gluten feed, oil-cake meal, flax meal, soy-bean cake, cotton-seed meal, peanut-oil meal, rice meal, rice polishings, tankage, fish scrap, alfalfa meal, molasses, feed flour, Kafir corn, screenings, potato cake, corn and clover silage, frozen shredded corn, oat fodder and oat silage, prairie hay, timothy hay, and oat straw, and various mixed and proprietary feeds.

Beef cattle, E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 361-392, pls. 4*).—Results of experiments with three lots of 4 steers each, lot 1 being grades showing a little beef blood, lot 2 medium butcher cattle, and lot 3 dairy steers, show that the ordinary steer of the country can be fed at a good profit if the feeding period is not more than five months.

Four lots of 6 Shorthorn steers each, lots 1 and 3 being classed as good butchers and lots 2 and 4 as good stockers, were fed, lots 1 and 2 receiving 50 per cent more roots and meal than lots 3 and 4, while half of lots 1, 2, 3, and 4 received in addition to their regular ration 2 lbs. of molasses per steer per day. The heavy-fed lots of stockers showed a greater increase in weight than the light-fed lots, but this was not true of the butchers. The greatest profits, therefore, were realized from the heavy-fed stockers and light-fed good butchers. In every case except one where molasses was added to the meal ration there was a decided increase in the total gain, but the increase was hardly sufficient to compensate for the high cost of molasses.

Three lots of 8 steers each, one rated as of the best type and kept loose, one of medium type and kept loose, and one of medium type and kept tied, made average daily gains for 121 days of 2.41, 1.83, and 1.64 lbs., respectively, at a cost per pound of gain of 8.34, 10.98, and 12.23 cts. Two uniform lots of 4 steers were fed for 121 days, one lot receiving an addition of 0.93 lb. molasses daily during the last 59 days. This lot made an average daily gain per head of 1.7 lbs. at a cost per pound of gain of 12.05 cts., as compared with 1.59 lbs. and 12.4 cts. for the check lot.

Three lots of steers, lot 1 being choice; lot 2, fair; and lot 3, dairy-type of steers, fed 135 days, made average daily gains per head of 1.69, 1.59, and 1.22

lbs., consuming per pound of gain 14.94, 15.81, and 20.65 lbs. of dry matter, and costing per pound of gain 14, 15, and 19 cts. for the respective lots.

Two lots of 19 and 12 steers, one fed tied and the other loose, made average daily gains per head of 1.4 and 1.6 lbs., consuming per pound of gain 17.71 and 15.43 lbs. of dry matter, and costing per pound of gain 16 and 14 cts., for the respective lots.

Two lots of 6 steers each, fed 143 days, lot 1 fed loose, and lot 2 tied, made average daily gains per steer of 2.01 and 1.46 lbs., realizing a profit per steer of \$11.20 and \$5.60 for the respective lots.

Two lots of steers fed 124 days, lot 1 on a light silage and a heavy grain ration, and lot 2 on a heavy silage and a light grain ration, made average daily gains per head of 1.193 and 1.371 lbs., and average profits per steer of 78 cts. and \$7.21. for the respective lots.

Two lots of steers fed 181 days, lot 1 on corn fodder and lot 2 on corn silage, in addition to the grain ration, made average daily gains per steer of 1.44 and 1.88 lbs., costing per pound of gain 10.02 and 7.7 cts., and realizing a profit per steer of \$1.13 and \$6.76, for the respective lots.

Six groups of steers of two lots each, two and three years old, respectively, were fed 160 days at Indian Head, Sask., as follows: Group 1, oat straw, prairie hay, and a meal composed of equal parts of barley and oats; groups 2 and 3, the same ration as group 1; group 4, oat straw, oat sheaves, and the same meal as group 1; group 5, oat straw, prairie hay, silage, and same meal ration as group 1; group 6, oat straw, prairie hay, silage, and a meal composed of barley, oats, peas, bran, and oil cake when finishing. Group 1 was fed outside, loose; group 2, inside, loose; groups 3, 4, 5, and 6, inside, tied. The steers fed loose gave far better returns than those tied. Steers fed outside gave larger profits than those similarly fed inside, tied, while those fed the same as the former two groups, but inside and loose, gave the best results of all. The results with those fed oat sheaves show little in favor of this ration, there being always a certain amount of waste, together with a lack of uniformity of quality in the feed.

Four lots of steers were fed as follows, in addition to the basal grain ration: Lot 1, alfalfa; lot 2, alfalfa and oat sheaves; lot 3, oat sheaves; lot 4, alfalfa and corn fodder. These steers made average daily gains per steer of 0.83, 0.96, 0.81, and 1.47 lbs., costing per pound of gain 23, 20, 19, and 11 cts., and realizing a net profit per steer of 38 cts., \$3.96, \$6.61, and \$3.15, for the respective lots.

Data are given on the cost of pasturing yearling steers at Lacombe, Alberta. These steers made average daily gains for a period of five months, on pasture, of 0.88 lb., at a cost per pound of gain of 3.72 cts.

Six lots of steers were fed during the winter 97 days at Lacombe as follows: Lot 1, green feed, inside; lot 2, timothy hay, inside; lot 3, silage and straw, inside; lot 4, prairie hay, outside; lot 5, in a corral, inside; lot 6, in the bush, outside. All lots received the ordinary grain ration. These steers made average daily gains per head of 1.51, 0.97, 1.055, 0.99, 2.14, and 1.52 lbs., at a cost per pound of gain of 8.75, 17.25, 12.98, 12.12, 5.93, and 9 cts., returning a profit per head of \$3.45, = \$2.50, 67 cts., \$1.01, \$7.90, and \$3.03. for the respective lots.

Sheep, E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 496-523, pls. 4*).—Six lots of lambs were fed 70 days as follows: Lot 1, a grain ration composed of oats, bran, and oil cake, 2:2:1; lot 2, 1 part of the above mixed with 1 part of elevator screenings; lot 3, complete ground elevator screenings; lot 4, complete ground elevator screenings, less blackseed; lot 5, ground blackseed; and lot 6, ground blackseed, 2 parts, and a molasses meal, 2 parts. These lots made average daily gains per head of 0.28, 0.31, 0.2, 0.29, 0.24 and 0.18 lbs., at a cost per pound of gain of 8.3, 6.2, 7, 5.4, 4.8, and 10.8 cts., with a net profit per animal of

54 cts., \$1.16, 80 cts., \$1.20, \$1.33, and 31 cts., for the respective lots. Lot 4, fed the pulverized screenings with blackseed removed, after the first two weeks apparently consumed the meal with relish. Lot 5, on pulverized blackseed, refused the ration almost entirely for five weeks, and at the conclusion of the experiment were consuming about half the quantity fed. Lot 6, on equal portions of pulverized blackseed and molasses meal, consumed the ration cleanly from the start. No toxic effect was noticed from the use of the by-product in any of its grades. These lambs when finished for market, all lambs receiving the same meal mixture, composed of oats, bran, and oil cakes, 2:2:1, made average daily gains per head for 55 days of 0.28, 0.19, 0.33, 0.33, 0.43, and 0.36 lbs., at a cost per pound of gain of 9.4, 13.5, 7.7, 8.6, 6, and 7.1 cts. Lots 5, 6, and 3, receiving blackseed in various proportions, were all losing weight at the end of the regular experiment, having apparently reached their limit of production on a roughage diet supplemented by inferior meal. The results of this finishing period indicate that the blackseed-fed lambs were held back during the experiment, as evidenced by their very rapid comparative gains during the finishing period.

Five lots of 11 lambs each were fed 135 days as follows: Lot 1, clover hay; lot 2, mixed clover and timothy hay and corn stover; lot 3, timothy hay and mangels; lot 4, clover hay and roots; lot 5, clover hay and oil cake. They made average daily gains per head of 0.085, 0.071, 0.084, 0.132, and 0.149 lb., at a cost per pound of gain of 18, 20, 18, 12, and 11.9 cts., for the respective lots.

The average results of three years' tests of clover hay, mixed hay and corn stover, and timothy hay and roots as roughage for fattening lambs, show the average daily gains per head for 3 lots of 42 lambs each to have been 0.107, 0.058, and 0.063 lbs., for 103 days, at a cost per pound of gain of 15.5, 24.7, and 20.4 cts., respectively.

Four lots of lambs were fed 108 days as follows: Lot 1, timothy hay and meal; lot 2, timothy hay, roots, and meal; lot 3, a mixture of timothy hay and broadleaf hay and meal; lot 4, a mixture of timothy and broadleaf hay and roots and meal. They made average daily gains per head of 0.215, 0.29, 0.209, and 0.274 lbs., at a cost per pound of gain of 11.1, 10.32, 12.39, and 11.68 cts., for the respective lots.

Three lots of breeding ewes were wintered as follows: Lot 1 in an open shed, fed alfalfa; lot 2 in a sheep barn, fed alfalfa; lot 3 in a sheep barn, fed mixed hay. They made gains per head of 5.6, 5.1, and 0 lb., while the lambs made a gain per head of 5.8, 0, and -6 lbs., for the respective lots.

Three groups of lambs of two lots each, bought at Lethbridge, Alta., one lot fed barley straw, prairie hay, and a grain mixture of oats and barley, 1:1, and the other lot fed barley straw, prairie hay, and wheat screenings, one group being fed in a closed shed, one group in an open shed, and the third group in the open, made average daily gains per head for 112 days of 0.13 and 0.13 lb. in the two lots of the first group, 0.2 and 0.9 lb. in the two lots of the second group, and 0.19 and 0.19 lb. in the two lots of the third group, at a cost per pound of gain of 11 and 11 cts., 7 and 8 cts., and 8 and 8 cts. for the respective groups.

In a corresponding test with lambs bought at Indian Head, Sask., the average daily gains per head were 0.12 and 0.12 lb. for the lots fed in the closed shed, 0.2 and 0.2 lb. for those fed in the open shed, and 0.15 and 0.16 lb. for those fed in the open, at costs of 12 and 12 cts., 7 and 7 cts., and 10 and 9 cts. for the respective groups.

A test in fattening a single pure-bred Shropshire wether indicated that the feeding of home-bred lambs may be profitable in Saskatchewan, while there is little or no profit in buying lambs.

Two lots of 240 lambs each were fed for 80 days, one lot receiving alfalfa and the other lot alfalfa and oat sheaves 2:1. The average daily gains per head were 0.021 and 0.024 lb. respectively, at a cost of 8.07 and 6.74 cts. per pound of gain.

Swine, E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 524-573, pls. 4*).—Three lots of shotes were fed 70 days, as follows: Lot 1, shorts, oats, and corn, 1:1:1, and skim milk, fed as slop; lot 2, shorts, oats, corn, and skim milk fed as slop, plus green rape; and lot 3, shorts, oats, and skim milk, plus ground corn. The pigs made average daily gains per head of 1.5, 0.995, and 1.13 lbs., at a cost per pound of gain of 5.5, 6.2, and 5.9 cts., for the respective lots.

Five lots of pigs were fed 84 days, all lots receiving skim milk; lot 1, corn, shorts, and oil meal, 3:3:1; lot 2, corn, shorts, and tankage, 3:3:1; lot 3, corn and tankage, 6:1; and lot 4, corn and tankage, 6:1; and lot 5, corn. These pigs made average daily gains per head of 0.9, 0.9, 0.95, 0.43, and 0.76 lb., at a cost per pound of gain of 3.06, 4.3, 3.5, 4.23, and 3.1 cts., for the respective lots.

Six lots of pigs were fed 42 days as follows: Lot 1, corn, shorts, and oil meal 1:1:1, and milk; lot 2, the same grain ration, blackseed, and milk; lot 3, blackseed and milk; lot 4, buckwheat screenings and milk; lot 5, complete screenings, flour, and milk; and lot 6, blackseed and water. These pigs made average daily gains per head of 1.05, 0.76, 0.14, 0.9, 0.48 and 0.01 lbs., at a cost per pound of gain of 4.7, 3.8, 7.6, 2.7, 4 and 36 cts., for the respective lots. "To summarize the value of blackseed in this experiment it is safe to say that the food value of this by-product is low even when fed in small quantities in a well-balanced ration containing good variety; that it has little food value when fed alone or in conjunction with only one or two other feeding stuffs; that animals of 160 lbs. weight can be made to eat 2 lbs. each per day and thus maintain weight for a short period of about a month and a half; that this product is rather unpalatable and, if constituting any considerable proportion of the grain ration, is unpleasant to the animals.

These lots were finished, all receiving for 42 days the same grain mixture, with the following results: An average daily gain per head of 0.57, 0.88, 0.88, 0.83, 0.64, and 1.26 lbs., at a cost per pound of gain of 7.3, 5.7, 4.7, 5.6, 4.7, and 4.69 cts., for the respective lots.

Three lots of sows were fed as follows: Lot 1, a regular grain mixture composed of bran, shorts, and cracked corn, 1:1:1, fed as a thick slop; lot 2, the same meal mixture except that one-fifth by weight of this mixture was replaced by tankage; and lot 3, whole corn in a hopper grinder, together with shorts and bran. In addition to the above grain ration all the sows received roots, clover or alfalfa hay, and skim milk. The amount and cost of feed per sow per day did not vary to any extent within the three lots except where tankage entered into the ration, in which case the cost was higher, the increase being proportionate to the amount of tankage used. The gain in weight of the sows before farrowing and loss during the eight weeks immediately after farrowing were fairly constant, with the smallest loss after farrowing in favor of the tankage ration. The condition of the young pigs at birth was in favor of the tankage ration. The average weight of pigs at birth was practically equal in all lots, while the weights at four weeks and eight weeks of age showed a slight increase in gain in each case in favor of the tankage ration. A comparison of lot 1, the check lot, with lot 3, where the grinder was used, showed only a slight advantage in weight in the litters at all stages of growth.

Four lots of 5 pigs each were fed 107 days as follows: Lot 1, barley chop; lot 2, barley chop and feed flour, 3:1; lot 3, barley chop and shorts, 3:1; and

lot 4, barley chop and oat chop, 1:1. These pigs made average daily gains per head of 1.37, 1.48, 1.32, and 1.24 lbs., at a cost per pound of gain of 4.79, 4.61, 4.87, and 5.63 cts., for the respective lots. It appears that barley chop is a good feed for fattening hogs, as all the hogs in the experiment made good gains. Oat chop and barley chop gave the poorest gains and the costliest gains. Oat chop is not deemed as good a feed for fattening hogs as the other combinations under test and at present prices costs too much. The addition of feed flour to the barley chop, even though it made a more expensive feed, increased the gains in weight and made the cost of production lower. Shorts did not give as good results as feed flour for mixing with barley; in fact, the barley alone in this test did slightly better than barley and shorts.

Three lots of weaning pigs were fed as follows: Lot 1, barley and skim milk; lot 2, shorts and water; lot 3, shorts and skim milk. These pigs made average daily gains of 0.52, 0.67, and 1 lb., at a cost per pound of gain of 5.92, 4.76, and 3.12 cts., for the respective lots.

Two lots of pigs were fed as follows: Lot 1, frosted wheat and water; and lot 2, oats, barley, and skim milk. These pigs made average daily gains of 1.37 and 1 lb., at a cost per pound of gain of 3.26 and 6.51 cts., respectively. In a second test, a lot of 5 hogs fed well-ground frozen wheat and water made an average daily gain per head of 1.83 lbs., and a similar group fed well-ground oats and barley 1.62 lbs. The respective costs per pound of gain were 4.12 and 4.82 cts.

It is estimated that the cost of feed per pig raised from the time of farrowing to weaning is \$2.32; the cost of raising young sows from weaning to six months of age, \$7.12; and the cost of raising young sows from six months to one year of age, \$9.49.

Continuing previous work (E. S. R., 33, p. 761), experiments in feeding phosphorus in various forms to pigs show a distinct benefit in feeding inorganic phosphorus with rice meal. In all, 129 pigs were put through the trials. Forty-nine of these were fed rice meal in various proportions with other grains and all developed the typical diseased condition previously noticed in rice-meal-fed pigs. Phosphorus in different forms was given as a complementary food to the above ration with 48 hogs. With one exception these hogs remained perfectly healthy throughout the trials and showed no ill effects from the rice meal. Calcium phosphate in smaller quantities fed to 4 pigs failed to counteract completely the injurious effects of a ration of rice meal. Liberal quantities of muriate of potash were absolutely ineffective in the case of pigs fed on a ration containing rice meal. Twenty-four control pigs fed on rations not containing rice meal remained normal and healthy throughout.

It is concluded that the injurious effects of rice meal in proportions as low as one-third of the total grain ration have received further confirmation. "Inorganic phosphorus added to the ration containing rice meal is capable of counteracting these injurious effects. From the work done, ground phosphate rock appeared to give better results than the other forms used. More work is necessary in this connection."

**Horses**, E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 474-495, pls. 6*).—Data are given on the cost of wintering idle horses. It was found during four years' observations that horses weighing around 1,250 lbs. can be fed, idle, for a little less than 10 cts. per day upon a pound each of rough hay, oat straw, and carrots or swedes to 100 lbs. live weight. The average total cost of feed for the period of 151 days was \$14.33 per head.

Experiments in wintering colts outside under single-boarded sheds when the temperature went down to as low as 31° F. below zero indicate that this prac-

tice may be successfully carried on. It takes a little more feed to keep up the necessary warmth, but against this extra cost may be placed the greater constitution of the horses.

Four lots of horses were fed as follows: Lot 1, oat straw, oat sheaves, oats, and bran; lot 2, oat straw, mixed hay, oats, and ground flaxseed; lot 3, oat straw, mixed hay, oats, and bran; lot 4, oat straw, alfalfa hay, oats, and bran. The most expensive ration was that in which flaxseed was fed, while that containing alfalfa hay followed next. The ration composed of mixed hay, oat straw, oats, and bran was the cheapest.

Two lots of idle work horses, one wintered on pasture during the day and stabled at night and the other kept in the stable, were kept at a total cost per horse per day of 13.5 and 12.8 cts.

It is estimated that the cost per day for feeding a colt rising one year old is 10.6 cts.; that of a colt rising two years old, 9.33 cts.; and that of a colt rising three years old, 6.08 cts.; or a total cost up to three years old of \$71.96. The average cost of carrying three fillies, one year old, during the summer was 6.95 cts. per pound of gain, the fillies making an average daily gain of 1.24 lbs.

The economy of mule production in the South and methods of management. H. K. GAYLE and E. R. LLOYD (*Mississippi Sta. Bul. 176 (1916), pp. 3-15, figs. 4*).—Data are given on the average cost of raising mules at the station of the three types: (a) The lighter type of "cotton mule," standing 14.5 hands high and weighing 800 lbs.; (b) the typical cotton mule, weighing 1,100 lbs. and standing about 15.5 hands high; and (c) the 16-hand 1,250-lb. farm work mule.

It is found that charging interest on all money invested at 8 per cent and 10 per cent depreciation in the value of the brood mare yearly, and valuing all feeds used at their average market value, mules are still produced at a good profit; the small mule at a profit of \$28.62 per head, the cotton mule at a profit of \$35.38 per head, and the heavy work mule at a profit of \$55.48 per head. "The farmer who can give the brood mare enough work to pay for her keep and depreciation can raise mules in the South for less than one-half their cost on the open market."

"Where the cost of keeping the mare must be included but no account taken of the interest on the money invested or her depreciation in value the small-type mule can be produced in the South for two-thirds his market value, the cotton mule for slightly over one-half his market value, and the better-grade farm mule for less than one-half his market value."

Report from the poultry division for the year ended March 31, 1915, F. C. ELFORD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 1101-1118, 1120-1152, pls. 12, figs. 2*).—Experiments to determine the effect of the shipping of hatching eggs show on the average a decrease of about 20 per cent in fertility and 23 per cent in hatchability in the shipped eggs. In comparative trials in marketing late pullets in the fall and in holding over until spring it was found that the latter method paid. It is estimated that the table scraps fed for four months from a family of three persons were worth in new-laid eggs \$6.59.

In experiments to test the possibility of using whey instead of skim milk in mixing the mash for crate-feeding poultry, three lots were fed as follows: Lot 1, skim milk; lot 2, whey; and lot 3, whey and beef scrap. The 11 birds in lot 1 and 12 birds in lots 2 and 3 made, during the three weeks' period, gains of 27.5, 13.5, and 10.5 lbs., costing per pound of gain 6.8, 12, and 16 cts., for the respective lots.

Two lots of 12 cockerels and capons each, fed three weeks during the fall, made total gains of 27.5 and 18 lbs., costing per pound of gain 6.9 and 10 cts., and bringing a total profit of \$13.41 and \$17.20, for the respective lots. A

second lots of 12 capons, fed until spring, made a total gain of 8 lbs. at a cost of 25 cts. per pound of gain, and bringing a profit of \$19.42. The fall cockerels sold for 20 cts. per pound and the fall capons for 25 cts., while the capons in the spring brought 35 cts.; but the capons sold in the spring had cost \$7.98 for feed to carry them over the winter. The capons grew in weight better than the cockerels before going into the crates, but did not do so well during the three weeks crate feeding, and the cost in the crates was more per pound. The higher sum received for the fall capons was just equivalent to what the 5 cts. higher price amounted to. The advisability of keeping capons until spring depends upon the amount of the greater price received for them.

Tests to determine the fertility of eggs after removal of the male indicate that there are traces of fertility even to the eighteenth day after removal.

Two lots of 12 hens each were fed 21 days as follows: Lot 1, a grain mixture made up of ground oats, corn meal, middlings, and beef scrap, 2:2:2:1, and moistened with water for feeding; and lot 2, ground oats moistened with skim milk. Both lots were fed 1 lb. three times per day for the first week, and 2 lbs. twice a day for the following two weeks. Water was given twice a day. These hens made average gains of 14.48 and 16.1 oz., and the food cost was 13.58 and 14.75 cts., per hen for the period.

Temperature records were kept of colony houses at Brandon, Manitoba, constructed as follows: Numbers 1 and 3, tar paper and one ply of boards with an extra ply of boards on the back; number 2, double boarded outside of studs all over; number 4, tar paper and one ply of boards; number 5, one ply of boards on the outside of studs and one ply on the inside of studs; and number 6, tar paper and one ply of boards on the outside of studs and boarded up on the inside of studs just around the roosts. Number 6 was always the coldest, but it had fewer hens and was the most exposed. Number 4 was the next coldest, but it had also few hens and was just enough warmer to allow for its extra shelter. Number 1 was the third coldest. It was well sheltered by bush and had plenty of birds, but was somewhat damp inside and some of the birds had their feet frozen. Number 2 gave much the same results as number 1, except that it was drier and did not have quite so much variation in temperature. Number 5 gave the best results of all. It was no warmer than number 3, but it had a much more uniform temperature than any of the other houses and was a great deal drier. Although number 3 was the same in construction as number 1, it was much warmer and drier. This may be explained by the fact that it had the greatest number of birds and was the center of the row.

The temperatures were also taken on the roosts with the curtains down around the roosts, and the difference between the temperature of the house outside the curtain and that of the roost noted. In every case the roost was warmer than the rest of the house, varying from a few degrees up to as high as 20° F. These results show that it is preferable to have a curtain to drop in front of the roost on really cold nights, as it adds considerably to the comfort of the birds. No influence on egg production can be traced to the effect of the houses, as differences in strain and age of the birds were more effective factors in determining the number of eggs laid.

Beginning on November 1, records of the eggs laid by the pullets and hens of each breed were kept. The Wyandotte pullets commenced to lay on November 13 and the Plymouth Rock pullets on November 19. From this time on during the entire winter the pullets gradually increased their egg production and the hens fell off in theirs till about the end of January. This shows that the pullet is essentially the winter egg producer. The White Wyandottes were

much superior to the Barred Rocks as winter layers, although about February 15 the Rock pullets began to lay better.

Temperature records were kept of colony houses at Indian Head, Sask., constructed as follows: Number 1, building paper and one ply lumber (two ply around the roost space), one sash glass, two cotton frames, board floor, and shingle roof; number 2, two ply lumber, tar paper between, all-cotton front, earth floor, shingle roof; number 3, two ply lumber, tar paper between, cotton front and also glass 14 in. wide full length of front, earth floor, shingle roof; and number 4, two-ply lumber, tar paper between, roost space sealed inside with beaver board, board floor, ruberoid roofing, all-cotton front. The winter was extremely mild, and no striking differences between the houses or the egg production was noted.

Records were kept of the temperatures in a large frame house at Lacombe, Alta., which accommodated about 100 birds, and in a straw house which has a floor space for about 80 birds. During the latter half of January, through February and the latter half of March, while the temperature was higher in the frame house, the birds in the straw house did not suffer.

The percentages of hatchability of eggs produced in the long, square log, and straw types of houses were 38.6, 56.9, 52.7, and 31, respectively.

Comparing the cost of 1,200- and 140-egg capacity incubators it was found that the former could be operated at a cost of 35 cts. and the latter at \$2.09, per 100 chicks hatched, the percentage hatched being 46.1 and 41.4, respectively.

The following table shows a comparison between the performances of early-hatched and late-hatched pullets:

*Early v. late hatched pullets.*

Breed.	Hatch.	No. of birds in pen.	Period.	Eggs laid.	Weight of eggs per dozen.	Cost of eggs per dozen.	Fertile eggs.	Total eggs hatched.
			<i>Days.</i>		<i>Oz.</i>	<i>Cts.</i>	<i>P. ct.</i>	<i>P. ct.</i>
White Leghorns.....	Early...	49	170	1,618	25.20	21.50	85.8	49.0
Do.....	Late.....	53	151	1,054	23.50	34.99	.....	.....
Barred Plymouth Rocks.....	Early...	46	170	2,242	23.48	23.98	80.3	32.3
Do.....	Late....	45	149	1,617	23.54	25.62	.....	.....

From an egg-producing point of view, with White Leghorns, it would appear that it is better to hatch them early and let them get their full growth on the range before putting them into laying pens. In the case of the Barred Rocks also the early-hatched pullets gave the more profitable returns, but there was not so much difference with this breed as with the Leghorns.

Early-hatched White Leghorns were compared as to performance with their mothers, two years old. The results indicate that pullets only should be relied on for winter egg production. The strong, healthy pullets in this instance gave better fertility and hatchability than did their mothers.

Comparing selected and unselected pullets, the results indicate that it pays to cull a flock and to keep only those of known egg-laying strain. Comparing 5 v. 32 females to 1 cockerel, the former method resulted in a higher fertility and hatchability of eggs.

Comparative costs of operating four incubators are given. The average cost for all machines was 2.88 cts. per chick. The total cost of raising chicks to five weeks of age under a stove heater was estimated to be 14.2 cts. per chick.

In trials to determine the effects of certain well-known feeds when fed exclusively, pen 1 was fed wheat flour, best grade, baked in cakes. After 31

days the birds all became weak in the legs, ate sparingly, and gradually became comatose. They were all dead on the forty-sixth day. Pen 2 was fed wheat flour, best grade, baked, and inorganic phosphorus. The eggs were small and yolks white. Two birds died with the same symptoms as those in pen 1. Another bird recovered and laid eggs, but showed leg weakness. Pen 3 was fed ground wheat, baked in cakes. The eggs were normal, and, aside from one weakling, the birds remained healthy throughout the trial. Pen 4 was fed rice meal, baked in cakes. The eggs were small, the yolk almost white. One of the birds was attacked and eaten by her mates, having become too weak to defend herself. Her bones were very pliable. The others improved after eating their mate. Pen 5 was fed rice meal, baked, and inorganic phosphorus. The eggs were small, the yolks very pale, but the birds stayed in good condition throughout the trial. Pen 6 was fed polished rice, boiled. The eggs were normal. The birds showed alternate periods of normal feeding and sickness. When feeding normally the droppings were very watery. Pen 7 was fed unpolished rice, boiled. The birds kept in good condition throughout, but the droppings were very watery. Pen 8 was fed cracked yellow corn, boiled. The eggs were very small but normal in color. The birds kept in fair condition, but the droppings were watery. Pen 9 was fed yellow corn meal, baked. The eggs were normal in size and color. One bird showed weakness in legs and trembling after 41 days, but twice made a temporary recovery. Pen 10 was fed corn meal, baked, and phosphorus. The eggs were normal and the birds kept in good condition throughout the trial. Pen 11 was fed a starvation allowance of corn, wheat, barley, oats, and peas. The eggs were normal and the birds were very hungry but were the most healthy and active of all the birds. Pen 12 received a normal quantity of corn, wheat, barley, oats, and peas. The eggs were normal and the birds kept in good condition all through the trial. The inorganic phosphorus used in the above trials consisted of equal portions, by weight, of ground phosphate rock and basic slag. This was supplied in very small quantities, but helped to keep the birds in better condition when fed on rations normally low in this element. Even in a ration of corn meal, which is not so deficient in phosphorus as some other feeds, there was a marked difference in the condition of the birds. Boiled rice and boiled corn seemed to have about the same laxative effect on the birds.

A large number of eggs were measured and weighed in order to find out what effect the extreme dimensions had upon the weight. It was found that an increase in length or width above the normal was not always accompanied by an increase in weight. It appears that the degree of tapering either at one or both ends has a greater influence on the comparative weight than either of the extreme dimensions.

From records kept it is estimated that it costs 21.9 cts. to hatch and rear one duckling to three weeks of age.

Studies on the physiology of reproduction in the domestic fowl.—XV. Dwarf eggs, R. PEARL and MAYNIE R. CURTIS (*U. S. Dept. Agr., Jour. Agr. Research*, 6 (1916), No. 25, pp. 977-1042, pls. 2, figs. 4).—This paper discusses (1) the different types of dwarf eggs in respect to shape and also in respect to contents; (2) the variability in respect to size and shape; (3) the interrelations of the variations in dimensions, shape, and size; (4) the frequency of the occurrence of dwarf eggs compared to normal eggs and of dwarf-egg producers compared to birds which do not lay dwarf eggs; (5) seasonal distribution of dwarf eggs; (6) dwarf-egg production by birds with normal and with abnormal oviducts; (7) the relation of dwarf-egg production by normal birds to the age of the bird and to the position of the egg in the clutch and litter; (8) physiological conditions which lead to dwarf-egg production; (9) the relation of the

production of dwarf eggs to other abnormal phenomena of reproduction which either occur in nature or have been experimentally produced; and (10) the contribution which the study of the physiology of dwarf-egg production makes to our knowledge of the normal physiology of egg production. The investigations were made at the Maine Station from February, 1908, to February, 1916, during which time 298 dwarf eggs were known to have been produced at the poultry plant of the station.

During the two years of maximum dwarf-egg production the ratio of dwarf eggs to normal eggs was 1:1,158. It was found that there were two distinct types of dwarf eggs in respect to their shape, the prolate-spheroidal type similar to the normal egg and the cylindrical type which is much longer in proportion to the breadth. Only 4.6 per cent of the eggs examined were of the cylindrical type. About two-thirds of the dwarf eggs examined contained yolk, which in the large majority of cases was not inclosed in a yolk membrane. A comparison of the mean egg size of the several groups of dwarf eggs confirmed the evidence obtained from a study of normal and multiple-yolked eggs (E. S. R., 31, p. 570) that the amount of yolk (or other nucleus) present in the oviduct is an important factor in determining the amount of albumin secreted in a given case. The correlations between yolk weight and egg weight and between yolk weight and albumin weight in dwarf eggs with small yolks were very high. Of the dwarf eggs collected during this investigation 70.8 per cent were laid during the five months from March 1 to July 31. The dwarf-egg production was also highest in proportion to the normal-egg production during the spring and early summer.

It was found that the production of a dwarf egg is usually an isolated phenomenon; that is, a bird usually produces only one such egg. The 251 dwarf eggs of known origin in these studies were laid by 200 birds. Of these 200 birds 178 produced 1 dwarf egg each, 15 produced 2 dwarf eggs each, 3 produced 3 dwarf eggs each, and 4 produced 4, 5, 8, and 17 dwarf eggs each, respectively. Most of these birds had a normal egg record, and the dwarf egg was preceded and followed by normal eggs.

A study of all the egg records and the available autopsy records for birds which produced one or more dwarf eggs showed that in most cases the disturbance which caused the production of the dwarf eggs was of temporary character and was not correlated with a morphological disturbance of the sex organs. The records of only 11 of the 200 birds showed evidence of a permanent disturbance of the egg-forming processes, and these 11 included all the cases where the bird produced more than three dwarf eggs, two that produced three, one that produced two, and four that produced only one dwarf egg. In these 11 cases few or no normal eggs were produced after the dwarf egg or eggs, although nesting records indicate that the ovary passed through normal reproductive cycles. Autopsies were made on five of these cases, and all of them showed some pathological condition of the oviduct which interfered with the passage of the egg, but did not entirely close the duct. Dwarf-egg production was found not to be associated with immaturity.

Data on the position of the dwarf egg in the clutch and litter show that the dwarf eggs may be produced at any time during the laying period. Of 183 dwarf eggs produced by normal birds which completed the period of production during which the dwarf egg was laid, 8 were first and 11 were last eggs in their respective litters. "A dwarf egg may be overtaken by a normal egg and form one of the components of a compound egg similar to a double-yolked egg, except that one part is a dwarf egg. A dwarf egg, after it has received its membrane or its membrane and shell, may be returned up the duct and be included in the succeeding normal egg, or it may act as the stimulus for the

formation of a larger inclosing dwarf egg. Dwarf eggs are produced only when the ovary is in the absolutely active condition associated with the maturing of yolks. This is true whether the bird has a normal or pathological oviduct. When the sex organs are in this condition, a mechanical stimulation of the oviduct by an artificial yolk may result in the formation of a complete set of egg envelopes."

The Shoup oat sprouter, MR. and MRS. G. R. SHOUP (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 6, pp. 12-20, fig. 1*).—In addition to notes on feeding sprouted oats and on oat sprouting devices for small flocks, directions are given for the construction and operation of an oat sprouter suitable for large flocks of laying hens.

### DAIRY FARMING—DAIRYING.

Dairy cattle, E. S. ARCHIBALD ET AL. (*Canada Expt. Farms Rpts. 1915, pp. 393-418, 426-473, pls. 8*).—From experiments in feeding elevator screenings to dairy cattle it appears that this material has a fair feeding value. The attitude of the individual cows to the screenings meal rations differed widely. Some showed little preference one for the other; others ate only portions for a few days; others refused it altogether, carefully cleaning up all the roughage with which the meal was fed and leaving practically all of the meal in the manger; others, again, refused throughout the entire period all feed containing screenings. With the exception, however, of certain animals that consistently refused the meal ration, the herd during the second week of the period, as a rule, consumed it cleanly. It would appear from these short tests that the value of screenings lies not in any palatability that it may add to a ration, and not conclusively in its power to produce, but rather in its cheapness.

In experiments comparing turnips and molasses for dairy cattle it was found that while the amount of roughage necessary to produce a pound of fat or milk is much lower where molasses is fed, the cost to produce, as figured on the values given, is increased when compared with the average results of the root-feeding periods, while the actual production of milk during the molasses-feeding period is slightly lower. In this experiment 254 lbs. of molasses, 5 lbs. of meal, and 6 lbs. of hay were equivalent to 1,890 lbs. of roots. It is concluded that while molasses may replace a part of the succulent ration, it can not wholly replace roots either from the standpoint of increased production or lessened cost.

In an experiment comparing corn silage and molasses for dairy cattle it was found that 252 lbs. of molasses was equivalent to 31 lbs. of meal, 20 lbs. of hay, and 1,039 lbs. of silage. It appeared that the replacing of 15 lbs. of silage with 4 lbs. of molasses resulted in an increase in milk production sufficient to offset the greater cost of the ration.

Five lots of calves were fed with the following results: Lot 1, fed on whole milk, clover hay, and roots, made good gains at a cost of 14.15 cts. per pound of gain; lot 2, fed on a home-mixed calf meal composed of ground oats, ground corn, and ground flax, 2:4:1, plus skim milk, clover hay, and roots, made gains costing 3.04 cts. per pound; lot 3, fed a commercial calf meal as a water slop, plus clover hay and roots, but with no skim milk, made satisfactory gains at a cost of 2.36 cts. per pound; lot 4, fed the same calf meal, skim milk, clover hay, and roots, made very satisfactory gains at a cost of 4.48 cts. per pound; and lot 5, fed another commercial meal, skim milk, clover hay, and roots, made very satisfactory gains at a cost of 3.01 cts. per pound.

Experiments with the milking machine showed that the cows did not materially decrease in their milk flow. The quantity of strippings produced after

the milking machine was quite variable, averaging from 0.125 to 1 lb. per cow per milking. The hand-produced milk contained, as a rule, less than one-third the bacterial content of the machine-produced milk. No ill effects whatever on the cows' teats resulted from the use of the milking machine.

Data are given on the cost of second-class Ayrshire heifers and first-class Guernsey heifers from birth to one year of age, also of Holstein heifers from the time they were yearlings until they dropped their first calf.

Four lots of calves were fed daily per head as follows: Lot 1, from 6 to 20 lbs. of whole milk, as needed; lot 2, from 10 to 20 lbs. of skim milk and a meal ration of oats, corn, and flax (all ground), 2:4:1; lot 3, a calf meal and water; lot 4, from 10 to 20 lbs. of skim milk and the calf meal. All the lots received hay and silage as required. They made average daily gains per calf of 1.91, 1.61, 0.87, and 1.6 lbs., at a cost per pound of gain of 9.32, 2.84, 12.33, and 5.42 cts., consuming per pound of gain 1.47, 1.47, 2.97, and 1.78 lbs. digestible matter for the respective lots.

Experiments were conducted to determine the best quantities of grain to be fed. All of the cows received the same quantity of roughage, hay, silage, and swedes. Two of them ate as much grain as they could clean up, which was about 1 lb. per 2.5 lbs. of milk; two others received 1 lb. of meal to 4 lbs. of milk; and the last two received 1 lb. of meal per 8 lbs. of milk. The results indicated that the cows which had the unlimited quantities of meal gave the most profit.

An experiment was tried in ensiling green alfalfa with corn. The two were not mixed, but were put in by the wagonload, in the proportion of one load of alfalfa to two of corn. The weight of the corn packed the alfalfa thoroughly, and its juices permeated it so that the alfalfa kept as well as the corn. It came out in excellent condition and was eaten with great relish by the cattle.

Ten lots of cows were fed as follows: Lots 1 and 3, peas and oats as silage; lots 2, 4, 6, and 8, peas and oats as green feed; lot 5, timothy hay; lot 7, turnips and straw; lot 9, prairie hay; and lot 10, corn silage. All the lots receiving in addition the ordinary grain ration. Judged from the standpoint of the cost to produce 1 lb. of butter the various fodders tested rated as follows: Peas and oats as silage; peas and oats as green feed; corn silage; turnips and straw; wild hay; and timothy hay. Peas and oats kept well as silage.

Fifteen head of cows were fed during four periods of 10 weeks each a ration composed of wheat bran, brewers' grains and oil cake, 5:5:2, and during two other periods, the same ration except that soy bean cake replaced the oil cake. They produced per cow per day 21.21 and 20.49 lbs. of milk having an average fat content of 3.17 and 3.09 per cent, consuming per pound of fat produced 10.95 and 11.68 lbs. of feed, and costing per pound of fat produced 35 and 36 cts., respectively. It appears that the linseed oil cake gave slightly the better results.

When cacao husks were fed in addition to a grain ration of brewers' grains and wheat bran, in the proportion of 2:5:5, the flow of milk decreased over 2 lbs. per day per cow, and the yield of fat was less. Although the total cost of the feed was less when the husks were fed the cost to produce a pound of milk or fat was increased.

Sixteen cows fed during two periods on corn silage and during another period on clover silage in addition to an ordinary grain ration, produced during the first two periods 19.61 lbs. and during the second period, 18.53 lbs. of milk per cow per day, having a fat content of 3.33 and 3.4 per cent, respectively, and costing to produce a pound of milk 1.12 and 1.14 cts.

From the results of the foregoing experiments it is recommended that linseed oil meal be fed in preference to soy-bean meal, even when combined with nitrog-

enous feeds, such as wheat bran and dried brewers' grains. If cacao-bean husks could be purchased cheaply they could be used to a limited extent to replace higher-priced grains in a succulent ration. If clover is cut when in bloom and properly made into silage it is a valuable form of winter feed for dairy cows.

Three lots of calves were fed as follows, in addition to a grain ration: Lot 1, linseed oil meal; lot 2, a commercial calf meal; and lot 3, skim milk. These calves made average daily gains per calf of 1.325, 1.038, and 1.39 lbs., at a cost per pound of gain of 8.23, 11.6, and 7.13 cts.

Cow records pay (*North Carolina Sta. Circ. 33, folio, figs. 7*).—Methods of keeping dairy records are explained, and a milk and feed record sheet is given.

Studies on the creaming ability of milk, B. W. HAMMER (*Iowa Sta. Research Bul. 31 (1916), pp. 67-91, figs. 5*).—The author found in these studies that wide variations exist in the creaming ability of various lots of milk and accordingly in the cream equivalents of 1 per cent fat. The individuality of the animal is an important factor from the standpoint of the creaming ability of milk as are also the stage of lactation of the animal and the breed.

"The temperature at which milk is held influences very materially the depth of the cream layer thrown up, low temperatures giving deeper cream layers than high temperatures. For the development of a deep cream layer on milk the milk should be held at as low a temperature as possible, although this temperature should be above the freezing point of milk. At ice-water temperature, in general, a deep cream layer is first formed and this gradually contracts as the milk stands. At room temperature, in general, a shallow cream layer is first formed and this increases as the milk stands. Commonly a definite cream layer is evident at room temperature earlier than at ice-water temperature. With the milk from individual animals low temperatures occasionally prevent the development of a definite cream layer. The original temperature ordinarily has little influence on the creaming ability of milk.

"Continued creaming tends to decrease the creaming ability of milk, although occasionally increases are observed. Continued creaming also decreases the distinctness of the cream layer. Agitation at ordinary temperatures does not necessarily decrease the creaming ability of milk and occasionally there is a slight increase. Clarification consistently causes a slight decrease in the creaming ability of milk, but this decrease is too small to be of any practical importance. Running milk through a separator and then mixing the cream and skim milk commonly causes a slight decrease in the depth of the cream layer developing on milk; the rate of the rising of the cream is also decreased. Wide variations are, however, encountered in the effect of separation on milk.

"Viscogen commonly increases the depth of the cream layer on milk and sometimes this increase is an enormous one; wide variations are, however, evident in the effect of a certain amount of viscogen. The use of viscogen to improve the creaming ability of milk can not be considered a legitimate method of increasing the depth of the cream layer. The addition of egg white commonly causes a slight decrease in the depth of the cream layer.

"A change in temperature influences the depth of the cream layer on creamed milk. With bottles a decrease in temperature increases the depth of the cream layer and an increase in temperature decreases it. With tubes a decrease in temperature increases the cream layer but an increase in temperature causes only a slight decrease which may be due simply to continued holding.

"In general, efficient pasteurization decreases the cream layer of milk. This decrease need not be a serious one if the pasteurization is properly carried out and the milk is properly held after pasteurization.

"Homogenized milk does not give a definite cream layer.

"Wide variations in the effect of the various factors on the creaming ability of milk are observed and are undoubtedly due, in part at least, to differences in the milk used."

The creamery and testers' license law. Report of the work for the year ended March 31, 1916, O. F. HUNZIKER and G. L. OGLE (*Indiana Sta. Circ. 55 (1916)*, pp. 36, figs. 4).—This circular gives rules and regulations governing the enforcement of the Indiana creamery and testers' license law, results of inspection under the law during the year, notes on the testing of cream, notes on the location, construction, equipment, and operation of cream stations, and lists of licensed testers and plants for the year.

Effects of binders upon the melting and hardness of ice cream, C. W. HOLDAWAY and R. R. REYNOLDS (*Virginia Sta. Bul. 211 (1916)*, pp. 19, figs. 7).—The experiment reported in this bulletin dealt with the relative value of some of the common binders and fillers from the standpoint of hardness and heat resistance of the ice cream and also the additional effect of varying percentages of fat when used with the same.

Series of samples of ice cream from 8, 19, and 30 per cent creams were frozen in a gallon hand freezer and made into brick 3 by 4.5 by 4 in. The brick were packed in ice and salt and allowed to harden for 12 hours, all the brick containing a given percentage of fat being made from the same cream and packed in the same ice and salt. The formula for the plain or control ice cream in each series was 1 gal. of cream, 53 cc. of vanilla, and 10.5 oz. of sugar. The filler ice creams were made with each kind of cream using this basal formula and 0.4 oz. of gelatin, 1 oz. of gelatin, 0.4 oz. gum tragacanth, and 0.4 oz. of cooked starch, respectively, per gallon. At the end of the hardening period the value of each filler was determined.

The apparatus used for determining the hardness of the brick is illustrated and described. The hardness was ascertained by measuring the penetration of needles of different diameters which were let fall from a constant distance (100 mm.) and upon which a known weight was acting. This work was done in a cold storage room at 0° C.

The brick was then removed to a room having a temperature of 25°. Each brick was taken out of its mold, placed upon wooden blocks, and reduced to a standard weight of 500 gm. Weights were taken each hour for four hours to show the amount of melting.

The hardness of the different kinds of 8 and 19 per cent creams ranked in the following order from hard to soft: (1) Cream containing 1 oz. of gelatin, (2) 0.4 oz. of gelatin, (3) corn starch, (4) gum tragacanth, and (5) the control cream. The different 8 per cent creams ranked the same as the above in melting resistance. The hardness of the 30 per cent creams and the melting resistance of the 19 per cent and 30 per cent creams also ranked the same as the above, except that the control cream ranked fourth, and the gum tragacanth filler cream fifth.

Ice cream without filler from 8 and 19 per cent creams was about equal in hardness, while that from 30 per cent cream was much softer. The melting resistance increased with the percentage of fat, especially between 8 and 19 per cent. With ice cream containing gelatin, the hardest and most heat-resistant cream was that with a medium percentage of fat and a large amount of gelatin. Gum tragacanth was found to produce a smooth, soft cream. As the percentage of fat increased with this filler, the power to resist pressure and heat decreased. Corn starch as a filler compared favorably with gelatin, but the starch cream was more granular than the gelatin cream.

A few recipes are given for making ice cream, together with directions for the preparation of ingredients in ice-cream making and freezing the cream.

### VETERINARY MEDICINE.

Third annual report of the commissioner of animal industry for the year ended November 30, 1914, F. F. WALKER (*Ann. Rpt. Comr. Anim. Indus. [Mass.], 3 (1914), pp. 38*).—This reports upon the occurrence of and control work with diseases of animals during the year.

Fourth annual report of the commissioner of animal industry for the year ended November 30, 1915, L. H. HOWARD (*Ann. Rpt. Comr. Anim. Indus. [Mass.], 4 (1915), pp. 62*).—The usual annual report.

[Report of the] department of veterinary science and bacteriology, W. B. MACK (*Nevada Sta. Rpt. 1915, pp. 14-19*).—In inoculation experiments conducted with equine anemia in an effort to determine whether or not it is transmissible conflicting and inconclusive results were obtained. The therapeutic work also gave negative results.

In a flock of 22 fowls in which an outbreak of chicken cholera occurred the disease was promptly checked through the injection of killed cultures of chicken cholera bacilli. In a flock of 63 birds injected twice, eight days apart, the disease was also checked, 19 having died between the treatments. Reference is made to work with contagious epithelioma in chickens, bulletins on which have been previously noted (*E. S. R., 34, p. 189; 35, p. 885*).

An acute disease of cattle, usually fatal, occurs in certain valleys close to the Sierra Nevada Mountains, extending along these mountains for a distance of about 150 miles. Investigations conducted have led to the conclusion that it is probably hemorrhagic septicemia.

The outbreak of rabies in neighboring States spread into northern Nevada in April, 1915. Brief reference is made to fatty degeneration of the muscles in suckling lambs in a small band of pure-bred Hampshire sheep.

A study of soy bean hay, A. C. WHITTIER (*Delaware Sta. Bul. 112 (1916), pp. 3-18*).—During the course of a feeding period of sheep and cattle in which soy-bean hay was used as a roughage much trouble was experienced in that the young animals were delivered in a weak and feeble condition which made their raising difficult, if at all possible. The trouble was abated by substituting corn fodder, hay, and silage for the soy-bean hay. This condition was deemed probably due to some constituent of the soy-bean hay, and a chemical study of the material was therefore made.

The regular feeding-stuff analysis reported does not differ in any respect from those usually reported, except in the percentage of nitrogen-free extract, which was somewhat higher. On analysis the ash was found to have the following percentage composition: Silica, 2.3; sulphur (from ash), 0.23; sulphur (wet oxidation), 0.25; sulphur soluble in 2 per cent hydrochloric acid, 0.15; phosphorus (total), 0.37; phosphorus (inorganic), 0.08; calcium, 1.21; magnesium, 0.48; potassium, 2.24; iron, 0.14; and aluminum, 0.1. The various forms of carbohydrate and nitrogenous materials present were also determined.

Examination of ligroin, ether, chloroform, and alcohol extracts showed volatile oils, glucosids, and alkaloids to be absent, thus excluding these substances as possible toxic agents of the hay.

Hydrolyses of the hay were made with water, 1, 5, 10, and 25 per cent sulphuric acid, 2 per cent sodium hydroxid, and 20 per cent hydrochloric acid, the last-named being found the best hydrolytic agent. A determination of the nitrogen distribution of the hydrolyzed material according to the Van Slyke

procedure (E. S. R., 26, p. 22) yielded the following figures: Ammonia, 7.61; melanin, 4.95; arginin, 5.81; cystin, 1.17; histidin, 8.29; lysin, 3.46; amino (in filtrate from bases), 37.3; and nonamino (in filtrate from bases), 11.17. It is indicated that the results do not show anything unfavorable in regard to the hydrolytic products of the soy-bean hay.

A substance soluble in 70 to 80 per cent alcohol and water was obtained from an alcoholic extract of the hay by precipitation with basic lead acetate. It was toxic for guinea pigs when fed with the food or injected subcutaneously. An extract obtained from alfalfa hay by a similar procedure had no effect when injected subcutaneously into a medium-sized guinea pig, thus indicating the material to be specific for soy-bean hay. The material obtained from the extract contained 19.35 per cent dry matter and 0.3 per cent nitrogen. A determination of the nitrogen distribution of the material was made, but was only partially successful.

**Studies on antibodies.**—I, **Analyses and nitrogen distribution of a number of antisera**, E. J. BANZHAF, K. SUGIURA, and K. G. FALK (*Collected Studies Bur. Lab. Dept. Health N. Y. City, 8 (1914-15), pp. 213-222*).—Analytical data on the hydrogen-ion concentration, moisture, ash, phosphorus pentoxid, and nitrogen of the following antisera are submitted in tabular form, together with the formol titrations: Anti-diphtheria globulin, anti-tetanus globulin, anti-tetanus serum, anti-streptococcus serum, anti-gonococcus serum, anti-meningococcus serum, and normal serum.

Data obtained from the analysis of normal serum, tetanus globulin, diphtheria globulin, Hartley's whole protein, euglobulin (ammonium sulphate method), and euglobulin (Panum's method) by the Van Slyke procedure (E. S. R., 26, p. 22) are also reported.

No very marked differences in the composition of the different preparations were found. The only points to which attention is called are the higher values for cystin of the tetanus and diphtheria globulins.

The intrapalpebral mallein test, GOODALL (*Jour. Compar. Path. and Ther., 28 (1915), No. 4, pp. 281-297, figs. 4*).—The results of the tests of a large number of military horses in Southwest Africa, together with the post-mortem findings of a number of the animals, are reported.

The intrapalpebral test is deemed a safe and reliable method in the diagnosis of glanders and far superior to the ordinary subcutaneous procedure. The advantages claimed for it over the classical subcutaneous method are summarized as follows:

Clinical cases give constant reactions to this method. Animals which had given double reactions to the subcutaneous test reacted to this method even during the height of the subcutaneous temperature curve. Doubtful reactors to the subcutaneous test can be retested by this method, and give reactions immediately afterward. Certain animals which have failed to react to the subcutaneous test, or which could not be tested by it on account of other diseases and high temperatures, can be tested by this method, and react if glandered. A safe diagnosis can be made on the local reaction alone. The local reaction is more delicate, and doubtful reactions are extremely rare. In ordinary cases temperature, local, and ophthalmic reactions can be obtained by one injection. Mules react to this test as readily as horses.

The reliability of cell proliferative changes in the diagnosis of rabies, J. B. HARDENBERGH and B. M. UNDERHILL (*Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 5, pp. 663-668, pls. 3*).—Investigations made of a large number of cases of suspected rabies have led to the conclusion that Negri-like bodies may occur in smear and section preparations from brains of animals dead from other causes than rabies and also in association with Negri bodies in

such preparations from rabid brains, but that true Negri bodies are only present in the central nervous tissue of animals which were suffering from rabies at the time of their death.

**Experimental epidemiology in tuberculosis, A. DISTASO** (*Jour. Infect. Diseases, 19 (1916), No. 4, pp. 628-637*).—Experiments are reported from which the author concludes that guinea pigs can become infected through contact. The infectivity follows a curve which is nil at the beginning of the infection, increases gradually to the highest point, and is afterward no longer dangerous.

“It seems that at the beginning of the process few tubercle bacilli are excreted, with which the new contact can easily deal and acquire a kind of resistance which preserves the animal when the excretion is at its acme; but, as soon as the infection goes on and the microbes swarm in the body, then massive doses are excreted. By this time the new contact is powerless to cope at once with this large quantity, and therefore the pathogenic process establishes itself, and this is made worse by the daily absorption of great quantities of virus.” This condition arose between the ninth and the thirty-third day after the infection.

“After this period a puzzling condition was observed. The guinea pigs no longer contracted the disease. It was assumed that at about this time the process of the encapsulation of the lesions began. Up to this time the virus had been wandering in the organism; after that period the organism had the power to form around the virus a wall which only let through the toxin, and perhaps a few microbes, or none, were excreted. Then the contacts could no longer be infected.”

Some experimental data to substantiate the fact that the channel of infection in tuberculosis in guinea pigs is chiefly through the nose are submitted.

The relation of the results of the experimental study to the epidemiology of human tuberculosis is indicated.

**A method of producing antigen for complement fixation in tuberculosis, H. R. MILLER and H. ZINSSER** (*Proc. N. Y. Path. Soc., n. ser., 16 (1916), No. 1-2, pp. 28-30*).—The authors have prepared an antigen for complement fixation in tuberculosis by grinding a weighed amount of bacillary substance with salt and subsequent suspension in distilled water until isotonicity is obtained. The antigen so prepared is not anticomplementary in quantities as high as 1 cc., and has given positive fixation in quantities as low as 0.02 cc.

**The fate of the mammalian tuberculosis bacillus in sparrows and chickens, L. VAN ES and A. F. SCHALK** (*Jour. Infect. Diseases, 19 (1916), No. 4, pp. 614-627*).—The authors at the North Dakota Experiment Station have observed that birds (common sparrows and chickens) into which mammalian tuberculosis bacilli are introduced, either by ingestion or by inoculation, die in a highly emaciated state, but are almost entirely free from any gross lesions characteristic of the disease. The birds were found to retain the organisms for long periods with their pathogenic characteristics fully preserved.

It is indicated from the results that it is possible that birds may serve as intermediary carriers and transmitters of mammalian tuberculosis. The results confirm in part similar observations made by Auclair<sup>1</sup> in pigeons.

**Bovine tuberculosis, C. M. HARING** (*California Sta. Circ. 155 (1916), pp. 19*).—This circular discusses the subject under the general topics of susceptibility, symptoms, etiology, modes of infection, methods of detection (intra-dermal, ophthalmic, and subcutaneous tuberculin reactions), indications for use and limitations of the various methods, and control and suppression of the disease.

<sup>1</sup>Arch. Méd. Expt. et Anat. Path. [Paris], 1. sec., 9 (1897), No. 3, pp. 277-281.

Quasi-continuous temperature records in healthy and tuberculosis bovine animals, especially in relation to the tuberculin test, P. C. V. JONES and G. S. WOODHEAD (*Jour. Compar. Path. and Ther.*, 28 (1915), No. 4, pp. 337-357, figs. 16).—The authors describe in detail a specially constructed apparatus for obtaining continuous temperature records in bovines. The apparatus consists essentially of a modified platinum electrical resistance thermometer encased in a silver tube with the coil connected by means of comparatively heavy flexible leads composed of a series of strands of copper wire to the Wheatstone bridge, on which the resistance (and temperature) is measured by means of the deflection of a galvanometer.

A special harness for holding the thermometer in place so that the animal is free to assume any position has also been devised and is described.

Normal (winter and summer), pre-tuberculin period, post-tuberculin period, and late post-tuberculin period temperatures taken in the vagina by the apparatus described are submitted in graphical form.

The diastase in the saliva of the ox, C. C. PALMER (*Amer. Jour. Physiol.*, 41 (1916), No. 4, pp. 483-491).—From experiments conducted at the veterinary research laboratories at the Minnesota Experiment Station it is concluded that the saliva of the ox contains a starch-splitting enzyme or enzymes, the amount varying in individuals and at different times in the same individual. This enzyme (or enzymes) is not a specific constituent of the saliva, but comes from the blood, which contains the same or similar enzymes in much higher concentration. The enzymes are destroyed when subjected to a temperature of about 65° C. for 1 minute. The enzyme (or enzymes) is deemed to be unimportant so far as digestive ability is concerned.

An attempt to use pilocarpin hypodermically to stimulate salivary secretion was unsuccessful on account of the diastatic power of the pilocarpin on the starch. The procedure used in the experiments described was to irrigate the mouth with water or a dilute solution of acetic acid followed by inhalations of strong acetic acid.

The blood serum used was obtained by bleeding from the jugular vein in the usual manner.

A simple method of obtaining serum for the agglutination test from cattle suspected to be suffering from contagious abortion, L. E. W. BEVAN (*Jour. Compar. Path. and Ther.*, 28 (1915), No. 4, pp. 277-280, figs. 2).—A tube for collecting blood for serological work which has been found to be superior to the usual pipettes used is described.

For preserving blood samples which are to be sent some distance for examination a preservative containing 3 gm. of boric acid and 0.9 gm. of sodium chlorid in 100 cc. of distilled water was found to yield satisfactory results. If it was desired to prevent coagulation the preservative solution described, but containing in addition 3 gm. of sodium citrate, was used.

The death and expulsion of the immature fetus as a standard for measuring the prevalence of cattle abortion, W. L. WILLIAMS (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 1, pp. 29-40).—A paper presented at the annual meeting of the American Veterinary Medical Association at Detroit, Mich., August 22, 1916.

The outlook for the control of cattle abortion, W. L. WILLIAMS (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 2, pp. 199-217).—A further discussion of this subject (E. S. R., 34, p. 336).

Case reports of lymphangitis in cattle caused by an acid-alcoholic-fast organism, J. TRAUM (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 2, pp. 254-257, pl. 1).—Reports are given of cases of lymphangitis of cattle which showed the

presence of acid-fast organisms that are more closely related to the streptothrix than are the mammalian tubercle bacilli.

The liver fluke disease, its treatment and control, J. MAREK (*Berlin. Tierärztl. Wehnschr.*, 32 (1916), Nos. 7, pp. 73-77; 8, pp. 85-90, figs. 4; 9, pp. 97-101, figs. 3; abs. in *Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 4, pp. 534, 535).—Tests were made of a number of bactericidal and parasitocidal substances thought to be taken up by the intestine and returned in the bile, but in all cases (steers and sheep) the flukes remained alive. Successful results, however, were obtained from the use of kamala and its preparations, either kamala depuratum or kamala venale being satisfactory. Fifteen gm. administered in two doses at 12 to 24 hour intervals to yearlings and older sheep, or divided into five doses for weak ones, were found to destroy the flukes in from three to eight days. The treatment of cattle with kamala was beneficial but not so satisfactory as in sheep.

The abstract is by M. C. Hall.

Investigation into "louping-ill" or "trembling," J. P. M'GOWAN (*Edinburgh: William Blackwood & Sons, 1915, pp. 51*).—"Louping-ill or trembling, according to the view propounded here, is divisible into two groups, true louping-ill and pseudolouping-ill. True louping-ill (which includes staggers or stomach staggers of hill farms and arable farms) is divisible into several varieties, as mentioned in the text. Specially, according to the view expressed here, does it include braxy or sickness and grass sickness, which are held to be the very acute forms of the disease. The disease milk sickness in lambs is considered also to be a variety of this same disease. . . .

"These diseases are considered to be essentially of the same nature, in that they are held to be caused by the same organism, *Bacillus bipolaris septicus ovium*. Epidemiologically they are considered to be different, in that while braxy is usually produced by eating rapidly large quantities of succulent material covered with hoar frost, true louping-ill in most of its varieties is considered to be caused chiefly by exposure to extreme degrees of temperature within a short interval. Milk sickness is considered to be in a restricted degree caused by contagion. The grass tick is held to be responsible for the production of the bulk of the cases of pseudolouping-ill. Navel-ill, with its attendant joint-ill, contributes some cases, while aggravated wool-ball, injuries, etc., add a few to the sum total included in this term. A discussion on possible means of prevention and treatment is embodied in the text."

Additional notes on pathological lesions of pigs fed rice meal, S. HADWEN (*Canada Expt. Farms Rpts. 1915, pp. 573, 574*).—This is an amplification of the findings reported the previous year (*E. S. R.*, 33, p. 775). The author's view that toxins are responsible for the lesions encountered, expressed in the previous report, is said to have been supported by subsequent examinations, although incomplete nutrition is the primary cause of the disease. He finds that as a result of malnutrition the alimentary tract does not function normally and toxic products are absorbed into the system. Four pigs which received phosphorus in addition to rice meal and grew well furnished a striking contrast to others which received no phosphorus, the latter having developed a neuritis and lost the use of their limbs.

Notes on the occurrence of petechial hemorrhages in the larynx and kidneys in hog cholera, H. P. HOSKINS (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 4, pp. 478-483, fig. 1).—"If we are to continue classifying hog cholera in the group of septicemic diseases, and accept the hemorrhagic lesions found in the kidneys, lymph nodes, intestines, bladder, lungs, etc., as a part of the pathological picture of this disease, the hemorrhages found in the mucous

membrane of the larynx should also be considered along with the other lesions mentioned.

"Hemorrhagic laryngitis has been found in about three-fourths of a series of 500 pigs, killed subsequent to inoculation with hog-cholera virus, these hemorrhagic lesions being in evidence most regularly in those animals killed and autopsied eight to eleven days after inoculation. In view of the fact that petechial hemorrhages in the kidneys occur in a number of different pathological conditions, veterinarians should be cautious about basing a diagnosis on this lesion alone, even though this lesion does appear in a very large percentage of cases of hog cholera due to the filterable virus."

Observations on 2,800 pigs inoculated with hog-cholera virus, H. P. Hoskins (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 6, pp. 817-829, fig. 1).—Observations and experiments on 2,800 pigs inoculated for the production of hog-cholera virus at the Minnesota state serum plant over a period of approximately two years are reported.

Of the pigs inoculated 390 (13.9 per cent) failed to succumb to the infection, and their reactions varied between wide limits, indicating all grades of susceptibility and immunity to hog cholera. No pig survived a temperature higher than 107.4° F. Only 8 per cent of the pigs weighing between 40 and 50 lbs. survived the inoculation, thus indicating the greatest susceptibility at this weight. Pigs weighing between 50 and 60 lbs. at the time of inoculation showed the greatest resistance. The resistance was found to slowly decrease, however, as the pigs became heavier. Pigs which failed to succumb reached the height of their reaction most frequently on the sixth day. Animals which died or were killed when moribund reached the height of their reaction most frequently on the seventh day.

A virus was obtained ("fixed virus") which could be depended upon to bring pigs down on the eighth day with a fair degree of regularity by frequent passages of a strain of virus through susceptible pigs and by carefully selecting the seed virus pig from each group. Pigs inoculated with virus of different ages up to 162 days succumbed quite regularly within a few days of the time necessary for the same virus to bring the pigs down when comparatively fresh. Virus 216 days old had lost its infectivity. Pigs inoculated with various amounts of the virus (1 to 10 cc.) came down in the regular time, regardless of the exact amount injected or the manner of introduction.

Failure to succumb is considered by the author to mean that the pigs either did not die of the disease or did not at any time become sick enough to warrant slaughter for the purpose of obtaining virus.

The attenuation of hog-cholera virus, D. J. HEALY and E. J. GOTT (*Jour. Infect. Diseases*, 19 (1916), No. 4, pp. 569-571).—The authors at the Kentucky Experiment Station, continuing the work on the etiology of hog cholera, report experiments in which the virus of the disease was so modified by incubation for 48 hours at 37° C. with hyperimmune blood that when injected it no longer rendered normal hogs sick but even protected them when they were later exposed to infection. The cholera virus incubated with normal rabbit serum for 48 hours at 37° was modified to the extent that one of three animals was protected against the disease.

It is indicated that "it is quite possible that the mixture of hog-cholera virus and hyperimmune blood which had been modified by incubation for 48 hours at 37° and then rapidly dried over sulphuric acid at a low temperature would indefinitely retain its power to protect hogs against cholera, and yet not sicken them."

Some points in connection with the pathology and epidemiology of swine fever, J. P. M'GOWAN (*Edinburgh: William Blackwood & Sons, 1915, pp. 40*).—“From investigations conducted on material obtained from three epidemics of swine fever, the view is enunciated here that *Bacillus suispestifer* may vary considerably in its biological reactions, and may even be considered to be a variant of *B. suisepiticus*.”

Paralysis of pigs, H. WEHRBEIN (*Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 2, pp. 238-244, pls. 2*).—A disease, commonly known as paralysis, which has proved to be a polyneuritis parenchymatosa, is endemic in Iowa, where it causes quite considerable losses. “Because of the course and the nature of the disease therapeutic measures are not advised, but prophylactically the elimination from breeding of all animals the offspring of which repeatedly incline to the disease, and of all diseased animals, even when recovered, and the eventual change to dry quarters and proper feed will most likely be successful.”

Parasites of hogs, K. W. STOUDEUR and W. E. SIMONSEN (*Iowa State Col. Agr. Ext. Bul. 43 (1916), pp. 8, figs. 2*).—A brief popular account of the more important parasites affecting swine.

Shipping fever of horses, J. R. MOHLER (*Jour. Amer. Med. Vet. Assoc., 49 (1916), No. 2, pp. 169-178*).—A review of the present status of knowledge of this disease, including reference to work by the Bureau of Animal Industry of the U. S. Department of Agriculture.

Experiments by this bureau are said to give support to the view that the *Streptococcus equi* of Shütz is the cause of strangles, the filterable virus of Poels the agent of influenza, and the cellular inclusions of Gaffky and Lührs the causal factors of contagious pneumonia. The bureau's experiments have demonstrated clearly that the filtered blood of influenza cases is capable of reproducing the disease in susceptible horses, while the inoculations of various bacteria recovered from such cases have thus far proved negative.

“The preponderance of evidence appears to be in favor of an ultravisible micro-organism as the cause of influenza, the lowered vitality occasioned by this virus paving the way to infection with the colon bacillus, coccobacillus, *Bacillus necrophorus*, *B. pyocyaneus*, staphylococcus, pneumococcus, and most important of all the various species of *Streptococcus*. . . . The action of the bacterial vaccines as used at the present time is chiefly to assist in preventing or controlling the secondary infections which are invariably associated with influenza, and this opinion is substantiated by the fact that the influenza vaccines when injected in the early stages of the disease frequently result in a mild type of an attack with shorter duration.”

A new disease in ducklings, F. C. ELFORD (*Canada Expt. Farms Rpts. 1915, pp. 1119, 1120*).—Numerous complaints were received during the summer of 1914 of a disease of ducklings from widely separated districts. One newly established commercial plant lost large numbers of ducklings that had been procured in the United States for foundation stock. The age at which they were shipped did not seem to make any difference, as apparently all were affected in the same manner.

Investigations showed that the trouble was not confined to ducklings, as growing ducks about six weeks of age were sometimes affected, though in the more mature ducks the symptoms were more pronounced and were often noticeable for some time before death. The disease is characterized by a discharge from the eyes and sometimes from the nostrils, and there appears to be an affection of the brain, as the head is thrown back until it touches the shoulders, the duckling often staggering backward until it falls over. In some cases the ducklings seemed to recover, although it was noticeable that under

excitement some of the symptoms were liable to recur and the ducklings would be taken with spasms while swimming and drown. In examinations made Wickware detected the presence in the blood of all affected cases of a parasite, which gradually disappeared as recovery took place. Further studies are necessary before the cause of the disease can be fully determined. See also a previous note (E. S. R., 33, p. 483).

The transmission of filaria by Chrysops, F. K. KLEINE (*Zschr. Hyg. u. Infektionskrank.*, 80 (1915), No. 3, pp. 345-349).—This paper relates to studies made in West Africa, where tabanids of the genus Chrysops, namely, *Chrysops dimidiata* and *C. silacea*, were proved to be capable of transmitting *Filaria loa*.

A new host for *Fasciola magna*, together with observations on the distribution of *F. hepatica* in Canada, S. HADWEN (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 4, pp. 511-515, figs. 5).—The coast deer (*Odocoileus columbianus*) is said to be a new host for *F. magna*. The liver taken from a host on Texado Island in the Straits of Georgia contained 18 large flukes. *F. hepatica* has long been a source of loss of coast sheep in British Columbia but is not known to occur elsewhere in Canada.

The occurrence of the giant nematode, *Diectothyme renale* (*Eustrongylus*) in the United States and Canada, W. A. RILEY (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 6, pp. 801-809).—Twenty-three definite cases of the occurrence of the giant nematode *D. renale* (*gigas*) in the United States and Canada are reported, of which 19 are here recorded for the first time.

## RURAL ENGINEERING.

Rural engineering and the war of 1914-1916, M. RINGELMANN (*Ann. Sci. Agron.*, 4. ser., 4 (1915), No. 10-12, pp. 296-381, figs. 44).—This is an extensive report on the influence of the European war on rural structures, rural hydraulics, and agricultural machinery in France.

Surface water supply of south Atlantic and eastern Gulf of Mexico basins, 1914 (*U. S. Geol. Survey, Water-Supply Paper 382* (1916), pp. 66+XXX, pls. 2).—This report presents the results of measurements of flow made during 1914 on the James, Roanoke, Pedee, Savannah, Altamaha, Apalachicola, Escambia, and Mobile rivers.

Surface water supply of Snake River basin, 1914 (*U. S. Geol. Survey, Water-Supply Paper 393* (1916), pp. 248, pls. 2).—This report, prepared in cooperation with the States of Idaho, Oregon, Nevada, and Washington, presents the results of measurements of flow made on the Snake River and its tributaries during 1914.

Well waters from farm homesteads, F. T. SHUTT (*Canada Expt. Farms Rpts.* 1915, pp. 163-169).—Analyses of 195 samples of Canada farm water supplies are reported, showing that 49 were pure and wholesome, 54 suspicious and probably dangerous, 36 very seriously polluted, while 56 samples were too saline for potable use.

"The cause of pollution in the larger number of instances is the access to the well of drainage of an excretal character from the stable, barn, or privy. The polluted wells, for the most part, are shallow, merely collectors of soakage water from the surrounding soil. When these wells are, for the sake of convenience, located near the farm buildings or in the barnyard, as is too frequently the case, contamination is practically inevitable.

"The bored or drilled well, tapping a deep-seated source, is undoubtedly safer and more reliable than the shallow, ground-water well. Where the latter must be relied on, the surroundings for a radius of, say, 50 yds. should be kept free from manure and filth. Preferably this area should be sodded. As a further

precautionary measure the shallow well may be lined to a depth of 10 or 12 ft. and to a thickness of, say, 4 to 6 in. with cement or puddled clay, the lining projecting, say, 6 to 12 in. above the mouth of the well, which should be protected with a well-fitting cover to keep out frogs, mice, etc."

Boiling of water and treatment with hypochlorite are discussed.

Flow of water into wells: **Approximate theory**, N. WERENSKIOLD (*Engin. News*, 76 (1916), No. 6, pp. 256, 257, figs. 2).—A formula is derived from mathematical analysis for finding the rate of flow of water into open wells.

Experience with wood pipes in New Hampshire, A. W. DUDLEY (*Jour. New England Water Works Assoc.*, 30 (1916), No. 3, pp. 318-323, pls. 2).—Summarizing experience with wood pipe for water supply, the author states that it possesses the following advantages:

"(1) It is preserved and not rusted or corroded by water. (2) It is not corroded by any substance or destroyed by acids or salts. (3) Its carrying capacity is 20 per cent greater than cast-iron pipe and remains constant, while that of metal pipe decreases with age. (4) It does not taint or affect fluids going through it. (5) It does not burst if frozen, the elasticity of the wood preventing it. (6) It requires less labor and experience to lay in place than metal pipe. (7) It can, when service pipes are not taken off, be laid in shallower ditches than metal pipe, for it is not easily affected by frost. (8) While more or less joints show slight leakage when the pipe is first filled, they soon swell up and give less trouble in the end than cast-iron pipe."

Influence of the algæ of submerged sand filters in water purification, F. DIÉNET and L. GIZOLME (*Compt. Rend. Acad. Sci. [Paris]*, 163 (1916), No. 5, pp. 127-130).—Experiments are reported, the results of which are taken to indicate that the purifying action of a submerged sand filter on water is a function of the development and vitality of the biological covering of algæ. This activity is thought to be measured by the reduction of the alkalinity of the water, especially with reference to the coli bacteria.

**Waterworks handbook**, compiled by A. D. FLINN, R. S. WESTON, and C. L. BOGERT (*New York: McGraw-Hill Book Co.*, 1916, pp. IX+824, figs. 411; rev., in *Engin. and Contract.*, 46 (1916), No. 6, pp. 123, 124).—This book gives an extensive and usable compilation of information, old and new, for the waterworks engineer and superintendent, the designer, constructor, operator, and inspector. It is divided into five parts.

Part 1, sources of water supply, deals with rainfall or precipitation, evaporation, run-off and stream flow, and ground water. Part 2, collection of water, deals with intakes, watershed development by reservoirs, masonry dams, rock-fill dams, earth dams, wells, infiltration galleries, and notes on some equipment for treating water. Part 3, transportation and delivery of water, deals with open channels, aqueducts, plate metal pipes, wooden pipes, and reinforced concrete pipes. Part 4, distribution of water, deals with cast-iron pipe and specials; distribution systems; valves, sluice gates, and hydrants; service meters; pumps, pumping stations, and equipment; distribution reservoirs, standpipes, and tanks; water consumption; hydraulic computations; masonry and puddle; non-ferrous metals (also corrosion of iron and steel); capacity and conversion tables; and miscellany. Part 5, character and treatment of water, deals with character of water; inspection of sources of supply, storage of water and improvement of reservoirs, sedimentation, aeration and chemical treatment, water softening, preliminary filtration and deferrization, filtration, and examination of water.

**Methods and cost of making a snow survey for irrigation system**, F. T. CUMMINGS (*Engin. and Contract.*, 46 (1916), No. 9, pp. 189-192, figs. 3).—This

article describes the methods and cost of making a snow survey, made in cooperation with the Weather Bureau of the U. S. Department of Agriculture, and reports the data obtained.

Subirrigation, A. P. SPENCER and C. M. BERRY (*Univ. Fla. Div. Agr. Ext. Bul. 5 (1916), pp. 12, figs. 8*).—This circular describes and illustrates methods of subirrigation employed in Florida in artesian areas.

The essentials for successful subirrigation are enumerated as (1) an abundant supply of water, (2) a subsoil or floor composed of clay, marl, or hardpan located at a depth of from 3 to 5 ft. below the surface to hold the water and prevent its escape downward; (3) a foot or more of coarse sand on top of the subsoil or bottom of the irrigated depth that will readily absorb and distribute evenly the water to be used in grading the artificial water table; (4) a topsoil of sandy loam that is neither too porous nor too compact and which will convey the water freely by capillary attraction; (5) land that admits perfect drainage [and has] a fall of about 1 in. to 100 ft.; and (6) land that is level without depressions or raised places.

"Wherever the foregoing conditions obtain and wherever the crops to be grown justify it, subirrigation should give satisfactory results, but with any one of these essentials lacking it is not likely to give satisfaction. The system also supplies drainage and aeration."

In the construction of a system a water main with supply pockets is located on the high side of a field. The supply pockets feed the irrigation tile which drain into stop pockets at the low side of the field which are connected with a drain.

Cost of pumping for irrigation, O. L. WALLER (*Washington Sta. Popular Bul. 104 (1916), pp. 11*).—This bulletin gives brief directions for the designing of an irrigation pumping plant and estimating the cost of plant and of pumping water, together with experimental data on the use of fuel or electricity in pumping.

The following table shows the number of gallons of gasoline, distillate, or crude oil and the kilowatt hours of electrical energy used under average farm conditions and practice to lift 1 acre-foot of water 1 ft. high.

*Fuel and electricity used for irrigation pumping.*

Horsepower required.	Gallons of gasoline, distillate, or crude oil used.				Kilowatt hours of electric current used.		
	Engine belted to a centrifugal pump.		Engine belted to a deep-well pump.		Horsepower required.	Kilowatt hours used.	Efficiency.
	Fuel used.	Efficiency of plant.	Fuel used.	Efficiency of plant.			
	Gallons.	Per cent.	Gallons.	Per cent.			Per cent.
2	1.14	0.15	1.80	0.10	2.5	3.25	0.31

35	.42	.41	.29	.60			

A list of 10 references to literature bearing on the subject is appended.

Cost of structures of the second unit of the Dodson north canal, Milk River Irrigation Project, Malta, Montana, A. E. BECHTEL (*Engin. and Contract.*, 46 (1916), No. 6, pp. 126-129, figs. 16).—Tables of cost data are given, together with descriptions and illustrations of the structures.

Irrigation of Thanh-Hoa, PEYTAVIN (*Bul. Écon. Indochine, n. ser.*, 19 (1916), No. 117, pp. 13-55, pl. 1).—The important features of an irrigation system in the residency of Anam in French Indo China are described.

The district covers 105,000 hectares (259,350 acres), of which 70,000 hectares are actually irrigable. The amount of water necessary is estimated at about 0.64 to 0.8 liters per second per hectare, making a total quantity of water, including rainfall, of 0.77 to 1.65 liters per second per hectare. The cost of the system is estimated at 12,000,000 francs (about \$2,316,000).

Irrigation practice in growing small fruits in California, W. A. HUTCHINS (*California Sta. Circ. 154* (1916), pp. 35, figs. 17).—This circular describes and analyzes irrigation practices in the important berry centers of the State, and is based on work done under cooperative agreements between the Office of Public Roads and Rural Engineering of the U. S. Department of Agriculture and the California State Department of Engineering and between the Office of Public Roads and Rural Engineering and the station.

Utilization of small waterfalls for drainage and irrigation, V. N. ROSTOVTSEV (ROSTOVTSEFF) (*Selsk. Khoz. i Lâsov.*, 250 (1916), Feb., pp. 179-223, figs. 25).—Several different types of hydraulic ram are described and illustrated.

Tile drainage, A. H. LEIDIGH and E. C. GEE (*Texas Sta. Bul. 188* (1916), pp. 26, figs. 18).—This bulletin, written from the viewpoints of both the engineer and the agronomist, gives general information on methods, requirements, and results of tile drainage in Texas.

Ditching and digging pole holes with dynamite, T. M. KNIGHT (*Engin. and Contract.*, 46 (1916), No. 3, pp. 66-68, figs. 7).—Descriptions of methods employed, together with diagrammatic illustrations and tabular data, are given.

Land clearing, P. H. MOORE (*Canada Expt. Farms Rpts.*, 1915, pp. 351-354, pls. 2).—The average cost per acre for clearing ready to plow 14 acres of Douglas fir, birch, maple, alder, and vine maple with thick undergrowth, was \$145.39. Pulling of stumps by cable and blocks after light blasting was found to be more economical than direct hauling. Burning was less expensive for felling trees than sawing, although the stump was frequently removed at greater expense. Splitting with explosives and burning was found to be the best method of handling a big tree after it is down.

Major results of stump removal investigation conducted by the University of Wisconsin, C. D. LIVINGSTON (*Engin. and Contract.*, 46 (1916), No. 3, pp. 53, 54).—Work conducted by the agricultural engineering department of the University of Wisconsin established the following points as good practice in stump clearing:

“Where the stumps are large it was found that from one-third to one-fourth the amount of dynamite necessary to entirely remove the stumps from the ground would crack them into several pieces so that one or more of them could be pulled. Stumps may be pulled easier and quicker when cracked. The hole left is not nearly so large as when either pulled whole or blown out entirely. The roots are cleaner, are easier to handle, dry quicker, and are more easily burned. On the loams and clays it was found that 20 per cent dynamite would do the same work as 40 per cent at a saving of 25 per cent on the dynamite bill. On the lighter soils the 30 per cent grades did as good work as the high kinds and cost about 10 per cent less. Forty per cent grades or higher are only needed on dry sands.

"Electrical blasting was found to be quicker to operate and far more safe than the old cap and fuse method. By the use of a blasting machine many charges may be detonated at the same time, either under the same or different stumps. This method enables the charges to be placed where they are most needed. The holes left are usually smaller and the cost is not greater when the results are taken into consideration. Stump pilers are necessary to efficient land clearing where mechanical pullers are used. When they are equipped with automatic tripping devices piling may be done at the same time as the stumps are being burned. When stumps are dropped on a burning pile a more complete burn is secured; some dirt may be left on the roots and they may be much greener and still burn. The jar of falling stumps is like continually poking a grate fire. . . .

"Explosives are extremely valuable in certain kinds of ditching work. No matter how wet, brushy, or stony the ditch line may be, if sticks of 60 per cent straight nitroglycerin dynamite can be located within 18 in. of each other in wet ground a serviceable open ditch can be made by the detonation of only one cartridge."

State highway mileage and expenditures for the calendar year 1915 (*U. S. Dept. Agr., Office Sec. Circ. 63 (1916), pp. 8, fig. 1*).—Considerable tabular data are reported on road expenditures and highway mileage during 1915, and a review of such matters for the past 12 years is given.

"During 1915 the total road and bridge expenditures in the United States amounted to about \$282,000,000, of which probably not over \$15,000,000 represented the value of the statute and convict labor performed on the roads. Of the cash expenditures of \$266,976,399, about \$40,000,000 was secured from local bond issues and \$53,491,651 from State funds. . . . A total of \$80,514,699 was expended under the supervision of the State highway departments in the construction of 12,437 miles and the maintenance of 51,769 miles of public roads.

"In 1904 the actual cash road and bridge expenditure in the United States averaged slightly less than \$28 per mile of rural roads. In 1915 the cash road and bridge expenditure had increased to an average of \$109 per mile of road, and while in 1904 New Jersey led the States with an average road expenditure of \$221 per mile, and Nevada was last with \$3.72 per mile, in 1915 New Jersey again had the highest expenditure of \$475 per mile of rural road and Nevada was last with approximately \$17 per mlie.

"While the total road and bridge expenditures have increased about three and one-third times during the last 12 years—the portion secured from local bond issues about eleven times and that from State funds twenty times—on the other hand, the portion of this expenditure secured from statute labor has decreased about one-half. Furthermore, in 1904 practically all of the State funds were applied to road construction, not to exceed 3 per cent being devoted to maintenance, while in 1915 about \$16,000,000, or 30 per cent, of the State funds were applied to maintenance and reconstruction. . . .

"During 1915 those States having State highway departments surfaced under such supervision about 8,000 miles, and also improved, by grading and otherwise, an additional 4,000 miles. Thus, of the really constructive road work in the United States last year about one-half was more or less directly under competent State supervision. In addition to this work of construction, the several state highway departments also supervised the maintenance of 51,769 miles of main and trunk line roads."

Proceedings of the thirteenth annual convention of the American Road Builders' Association (*Proc. Amer. Road Builders' Assoc., 13 (1916), pp. X+264*).—The following special articles are included in these proceedings: Recent Development in the Building of Concrete Roads, by W. D. Uhler; A Con-

tractor's Suggestion to Engineers and Inspectors, by J. H. Gordon; Different Conditions and Localities, by F. C. Pillsbury; Roads at Low Cost for Moderate Traffic, by F. E. Everett; Foundations for Road and Street Pavements, by J. W. Hunter; Brick Streets and Roads, by H. E. Breed; Recent Tendencies in Stone Block Pavements, by C. F. Knowlton; and The Functions Performed by Stone in the Bituminous Concrete Pavement, by R. B. Gage.

**Unit stresses for timber: Manufacturers' table** (*Engin. News*, 76 (1916), No. 6, p. 273).—Working unit stresses for structural timbers used in dry locations are given in the following table:

*Working unit stresses for structural timbers used in dry locations.*

Species of timber.	Bending.		Compression.	
	Stress in extreme fiber, per square inch.	Horizontal shear per square inch.	Parallel to grain "short columns," per square inch.	Perpendicular to grain, per square inch.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>

New dairy cattle barns, E. S. ARCHIBALD (*Canada Expt. Farms Rpts.* 1915, pp. 418-424, pls. 9).—Plans, photographs, and brief specifications for the dairy barns recently constructed at the Central Experimental Farm at Ottawa, Ontario, Canada, are given.

The homemade stave silo, J. N. PRICE (*Wash. State Col. Ext. Dept., Ser. 1, No. 24* (1916), pp. 16, figs. 18).—It is the purpose of this publication to give bills of material, illustrations and full instructions for building the stave silo with either plain or tongued and grooved staves and with either of the two types of doors.

Pit silos and how to make them, A. L. PASCHALL (*Ariz. Col. Agr. Ext. Serv. Circ. 8* (1916), pp. 28, figs. 22).—This circular contains a compilation of the experiences of farmers in Cochise and Santa Cruz counties, Ariz., with pit silos, together with information on the subject from several of the state agricultural experiment stations.

## RURAL ECONOMICS.

Can the farmer realize higher prices for his crops by holding them? J. E. POPE (*Quart. Jour. Econ.*, 30 (1916), No. 4, pp. 805-831).—The author, after studying the variation in the monthly prices of important agricultural products, the cost of storage, interest, and other expenses of holding crops, concludes that in the long run it will not pay the farmer to follow this practice.

Marketing farm produce by parcel post and express, B. H. HIBBARD and A. HOBSON (*Amer. Econ. Rev.*, 6 (1916), No. 3, pp. 589-608, figs. 8).—The authors point out that it is feasible to market only a small portion of the farm products

by these methods and compare parcel-post and express rates and the limitations in their service.

**The intrinsic values of grain, cotton-seed, flour, and similar products, based on the dry-matter content, E. G. BOERNER** (*U. S. Dept. Agr. Bul. 374 (1916), pp. 32, figs. 3*).—In this report is pointed out the fact that the water contained in grain, cotton seed, and similar products adds nothing to their intrinsic value, while in many ways the excess of moisture is detrimental. The methods of determining the comparative value of dry matter and the advantages of buying and selling on a dry-matter basis are discussed. A series of statistical tables are included, showing the comparative values, on a dry-matter basis, with varying moisture contents.

**Monthly crop report** (*U. S. Dept. Agr., Mo. Crop Rpt., 2 (1916), No. 9, pp. 85-96, figs. 4*).—This report contains the usual data regarding crop conditions, estimated farm values of important farm products, and range of prices of agricultural products at important markets, and special reports and data on hogs, honey bees and honey plants, cotton, pecans, rice, cranberries, and beans, onions, cabbage, and other truck crops. It also shows the estimated apple crop by varieties, and the wheat production in some of the principal wheat-producing countries of the world. There is also shown a diagram giving the variation in prices of hogs and corn over a series of years.

**Statistical tables relating to wheat, G. F. SHIRRAS** (*Dept. Statis. India, Statis. Tables Wheat, 1916, pp. II+32, pls. 4*).—In this report are given the area and yield of wheat in India by Provinces and in selected countries, the imports and exports, and the monthly movement and prices, together with the trade of the United Kingdom.

**Farmers' cooperative corporations, A. E. CANCE and L. J. JEFFERSON** (*Bul. Vt. Dept. Agr., No. 24 (1915), pp. 48*).—The authors have discussed the essentials of successful cooperation, the fundamentals of a cooperative corporation, possible fields for cooperation among farmers, standardization, federation of cooperative societies, and how to form farmers' exchanges. There are also included forms for incorporating and for organizing cooperative organizations. A brief bibliography is appended.

**Eugenics and agriculture, O. F. COOK** (*Jour. Heredity, 7 (1916), No. 6, pp. 249-254*).—The author maintains that city life sterilizes the best lines of descent on a large scale, and therefore that population must be held on the farm if the race is to improve.

The article concludes with the statement that "to recognize the relation of eugenics to agriculture does not solve the problems of our race, but it indicates the basis on which the problems need to be solved, and the danger of wasting too much time and effort in attempting to salvage the derelict population of the cities. However important the problems of urban society may be, they do not have fundamental significance from the standpoint of eugenics, because urban populations are essentially transient. The city performs the function of elimination, while agriculture represents the constructive eugenic condition which must be maintained and improved if the development of the race is to continue."

**Community centers, R. V. PHELAN** (*Bul. Univ. Minn. No. 25 (1915), Gen. Ser., pp. 15, figs. 6*).—This pamphlet contains a proposed model constitution, suggestions as to the purpose of organization, methods of organization, and topics for discussion and study.

**The church and country life**, edited by P. L. VOET (*New York: Missionary Ed. Movement U. S. and Canada, 1916, pp. XI+273*).—This is a report of a conference held by the Commission on Church and Country Life under the authority of the Federal Council of Churches of Christ in America, at Columbus,

Ohio, in December, 1915, and contains the reports of the different committees appointed by the commission. See also a previous note (E. S. R., 34, p. 297).

**Country life questions and answers** (*Missouri Bd. Agr. Mo. Bul.*, 14 (1916), No. 4, pp. 89, fig. 1).—This bulletin contains a number of papers dealing with the problems of the rural school, the country church, and various other phases of country life.

**Bibliography on country life, the farm, and the small town** (*Ind. State Libr. Bul.*, 10 (1915), No. 4, pp. 11).—This bibliography contains a list of publications dealing with these three topics in general and with special phases, such as the rural church, the rural school, roads, health and recreation, cooperation, buildings, grounds, machinery, the home, town planning and beautifying, sanitation, fire protection, business, and organizations.

**Rural progress in Missouri**, W. L. NELSON (*Missouri Bd. Agr. Mo. Bul.*, 14 (1916), No. 3, pp. 29, figs. 2).—This bulletin discusses the relative efficiency of farmers in Missouri as compared with other States, using the Census data as a basis.

**Statistical report of the California State Board of Agriculture, 1915** (*Statis. Rpt. Cal. Bd. Agr.*, 1915, pp. XXII+435).—This report contains a brief description of the physical and agricultural conditions in California by counties, with detailed statistics relative to agricultural production.

[**Agricultural resources of Rhode Island**] (*Prelim. Rpt. Com. Inquiry Agr. Resources R. I.*, 1916, pp. 30).—This is a preliminary report of the Commission of Inquiry into the Agricultural Resources of the State, made to the General Assembly, and indicates how the agricultural conditions in the State may be improved through cooperation among the farmers and between the various organizations already existing. The principal production and marketing problems in connection with the present systems of agriculture are described, especially as they relate to the dairy industry.

**The agricultural situation in the Philippine Islands**, H. T. EDWARDS (*Philippine Agr. Rev. [English Ed.]*, 9 (1916), No. 2, pp. 60-73).—The author calls attention to the changes in the area devoted to the production of rice, corn, coconuts, sugar, tobacco, and Manila hemp, and to the changes in the number of live stock. He also discusses the relationship of the government work to the development of the agriculture of the islands.

**The farm prize competitions**, C. S. ORWIN (*Jour. Roy. Agr. Soc. England*, 76 (1915), pp. 201-237, figs. 7).—This article contains a brief description of the agriculture of the counties of Derbyshire, Leicestershire, and Nottinghamshire, and of the systems of management on farms awarded the prizes. The farms were divided according to the systems of management into two classes—the arable and the grazing or dairy farms.

**Agricultural statistics of Galicia and Bukowina, 1914** (*Anbauflächen und Ernteergebnisse der landwirtschaftlichen Bodenprodukte in den im Reichsrate vertretenen Königreichen und Ländern mit Ausnahme Galiziens und der Bukowina, 1914*. Vienna: Govt., 1915, pp. 49).—This report contains statistical data concerning the acreage and production of the principal agricultural crops of Galicia and Bukowina for 1914, with comparisons for earlier years.

[**Agriculture in the Commonwealth of Australia**], G. H. KNIBBS (*Off. Year-book Aust.*, 8 (1901-1914), pp. 221-386, figs. 5).—These pages contain the information previously noted, with data for a later year (E. S. R., 33, p. 193).

## AGRICULTURAL EDUCATION.

**A state system of agricultural education**, K. L. BUTTERFIELD (*Mass. Agr. Col. Bul.*, 8 (1916), No. 2, pp. 29-47).—A brief review of the history of agricultural education in Massachusetts, beginning with the incorporation by the legislature

in 1792 of the Massachusetts Society for the Promotion of Agriculture, which still exists, is followed by a discussion of some characteristics of a state system of agricultural education, the types of work to be recognized, the groups of persons to be reached, and the scope and administration of and necessary machinery for agricultural education.

**County training schools in Alabama, J. L. SIBLEY** (*South. Workman*, 45 (1916), No. 7, pp. 407-412, figs. 6).—This article describes a new type of school for negro youth, known as the county training school, which is being developed in the South in cooperation with a number of educational agencies.

The schools cover from 8 to 10 grades of work and offer three courses, viz. agriculture for boys, household arts for girls, and teacher training during the last year for those who desire to teach in the rural schools of the county. In Alabama three schools are already in operation.

As soon as funds permit each school is to have a teacher's home so that the school can be made the center of community life. The aim has been to secure some 10 acres of land for the school site and small demonstration plot. Extensive agricultural work is not to be done on the school grounds, as it is thought that club work with boys and girls at their homes and demonstration work with their parents will prove more effective.

The principals and industrial teachers are employed by the year, the purpose being to have them work in the community during the summer vacation months. During the past two years annual farmers' conferences, annual county teachers' institutes, and community fairs have been held at the schools. Two of the schools will give short summer courses for teachers now at work in the county. A supervising industrial teacher makes her nominal headquarters at the school, but works mainly out in the rural communities. One or two days of each month she devotes to the training school, helping the teachers in their industrial classes, and addressing the students on the needs of the rural schools.

**Decline and fall of a state system of boys' and girls' agricultural clubs, J. MAIN** (*School and Soc.*, 3 (1916), No. 67, pp. 514-520, fig. 1).—The author describes the system of boys' and girls' agricultural clubs in operation at the Oklahoma Agricultural and Mechanical College until the fall of 1914, when the Federal system of clubs was substituted for it. He considers the following peculiarities of this state system as contributing to the decline of the club movement: The unfortunate conception of a "club"; overemphasis of prizes to the exclusion of the educational purposes of the organization; disproportionate prizes or a lack of careful supervision in the application of prizes to avoid over-emphasizing some things to the exclusion of others equally important; misfit projects and failure to induce local initiative; propriety of scholarships based on projects; inflation of membership; and political connections. The author finds that the system "as a propaganda did a great deal of good to the college and to its membership by making a place for the club idea, as well as in the lessons to be learned from its shortcomings. But the time always comes to a propaganda when it should give place to more conservative and constructive organization. And that time has arrived for all phases of agricultural education."

**School gardening a fundamental factor in education, L. H. HARVEY** (*Nature-Study Rev.*, 12 (1916), No. 4, pp. 178-183).—The author, in analyzing the influences of soil contact as it reacts upon the child, holds that garden work is auto-educative to an extent unequaled by any influence which the graded school can bring to bear upon the child; creates producers, instills civic interest, and engenders the esthetic; develops the faculty of cooperation; fosters adaptability, resourcefulness, and self-reliance; and forms the missing link between the home and the school.

**Report on the work of the Direction of Agriculture for 1913** (*Dept. Landb., Nijv. en Handel [Netherlands], Verslag Dir. Landb., 1913, pp. VII+71*).—This is a report on the activities of the Direction of Agriculture of the Netherlands in agricultural instruction, investigation, and extension work in 1913.

**Illustrated lecture on the production of alfalfa east of the ninety-fifth meridian**, H. L. WESTOVER and H. B. HENDRICK (*U. S. Dept. Agr., States Relations Service Syllabus 20 (1916), pp. 17*).—This lecture, which is intended for farmers' institute and other extension lecturers, gives a brief history and description of alfalfa, directions for growing and harvesting, and a discussion of its feeding value. The syllabus is illustrated with 51 lantern slides.

**Illustrated lecture on corn production**, C. P. HARTLEY and H. B. HENDRICK (*U. S. Dept. Agr., States Relations Service Syllabus 21 (1916), pp. 24*).—The authors briefly discuss the corn yield of the United States and give instructions for growing, harvesting, and storing corn. The syllabus is designed to aid farmers' institute and other extension lecturers in presenting this subject before popular audiences, and is illustrated by 52 lantern slides.

**The North Carolina corn bulletin**, E. E. BALCOMB (*N. C. State Supt. Pub. Instr., Teachers' Bul. 24 (1915), pp. 80, figs. 28*).—This publication has been prepared to help teachers of North Carolina in giving instruction on corn to their classes. It treats of the celebration of Corn Day, the importance of corn and its products, the history of the corn plant, corn growing, judging, testing, selection, improvement, and harvesting, and corn pests and diseases, and suggests a field exercise, the systematic preservation of information by means of agricultural booklets, with directions for making them, and industrial work connected with corn, arranged by months.

**Illustrated lecture on orchard management**, H. M. CONOLLY and E. J. GLASSON (*U. S. Dept. Agr., States Relations Service Syllabus 23 (1916), pp. 15*).—Directions are given for selecting the site for and planting the orchard, soil management, pruning, thinning, rejuvenation, spraying, protection from rodents, injurious insects, and diseases. The syllabus is illustrated by 50 lantern slides, and has been prepared for the use of farmers' institute and other extension lecturers in presenting this subject to popular audiences.

**Illustrated lecture on how to make good farm butter**, J. H. McCLAIN (*U. S. Dept. Agr., States Relations Service Syllabus 19 (1916), pp. 10*).—This lecture compares the old and new methods of butter making. The syllabus is illustrated with 51 lantern slides, and has been prepared to aid farmers' institute and other extension lecturers in presenting the subject before popular audiences in the Southern States.

**Dairying project**, C. A. NORCROSS and V. E. SCOTT (*Agr. Ext. Univ. Nev. Bul. 2 (1916), pp. 20, figs. 11*).—The dairy project work outlined in this bulletin for the members of the boys' and girls' animal husbandry club includes a 4-months' practical course in the study of milk, its composition, care, handling, and sanitation, herd management, feeds and feeding, etc., the use of the Babcock test, and keeping herd records. Members satisfactorily completing the course are awarded a certificate which authorizes them to contract with farmers to test a limited number of dairy cows once a month during one year under the supervision of the State leader in dairying and to charge at the rate of \$1 a head therefor.

**Illustrated lecture on cattle-tick eradication** (*U. S. Dept. Agr., States Relations Service Syllabus 22 (1916), pp. 14*).—This lecture deals with the life history of the cattle tick, the beginning of tick eradication and reasons therefor, cause of the disease, other kinds of ticks, losses occasioned by cattle ticks, methods of eradication, areas freed of ticks, cooperation between the Bureau

of Animal Industry of this Department and state authorities, live stock development following tick eradication, and what this Department will do to assist in eradicating the tick. The syllabus is designed to aid farmers' institute and other extension lecturers and is illustrated with 50 lantern slides.

**Manual training for the rural schools, L. M. ROEHL (Milwaukee, Wis.: Bruce Publishing Co., 1916, pp. 45, figs. 48).**—This text for rural schools consists of a set of farm and farm home woodworking problems. Each problem gives lists of the material and tools required, together with a stock bill and directions for making the article.

**Correspondence courses for teachers. Course III. Home economics (Corresp. Courses Teachers [Iowa Agr. Col.], Agr. Ext. Dept., Course III, Assigns. 1, pp. 28, figs. 5; 2, pp. 30, figs. 2; 3, pp. 26; 4, pp. 31; 5, pp. 27; 6, pp. 32, fig. 1; 7, pp. 35; 8, pp. 29, fig. 1).**—Lessons are outlined for the use of teachers in rural and graded schools on the location, ventilation, and lighting of the home, the disposal of wastes, control of dust, care of milk and butter and other food supplies, dish washing, prevention of contagious diseases, care of the sick, food principles and their uses in the body, composition and uses of various food-stuffs and their value in the diet, together with recipes, preservation of food, hot and cold beverages, home management, personal hygiene, serving meals, and digestion.

**Home economics: Its opportunities and obligations, ISABEL BEVIER (School and Soc., 3 (1916), No. 73, pp. 737-740).**—This article treats of home economics as one of the agencies in the education of women. After briefly indicating the meaning and content of home economics and its possible points of contact with the training of individuals, the author considers the following as the opportunities and obligations: (1) To teach the technique of household processes, to restate what was best in the old forms of family life in new terms; (2) to teach the meaning of economy and the principles which underlie it; (3) to bringing once again into honorable repute the business of housekeeping, to apply it to the usages which obtain in other business enterprises; (4) to supplement the training of the nurse in technique and the diagnosis of the doctor by showing the value of adapting the diet to the needs of the individual; (5) to teach a new definition for art; (6) through the Smith-Lever Act, to better the life in the farm home; and (7) to teach the unity of life and knowledge through schools and clubs and homes so that all will cooperate to the common welfare.

**The interdependence of forest conservation and forestry education, J. W. TOUMEY (Science, n. ser., 44 (1916), No. 1132, pp. 327-337).**—The author discusses the progress made in this country (1) toward forest conservation, (2) in the educational propaganda, begun more than a century ago, which made possible the public ownership of approximately one-fifth of the total area of forests in the United States, and (3) in the technical training in the science and art of forestry, which had its beginnings within the past two decades.

It is shown that in a space of 15 years, or prior to December, 1915, 1,185 men had been granted degrees in forestry in the 22 institutions in the United States offering technical courses in forestry leading to a degree. About one-half of the degrees have been undergraduate degrees given for four years of collegiate work. Advanced degrees in forestry are offered by 10 institutions. In April, 1915, out of 1,037 men who had then received degrees, 803 were reported as actually engaged in forestry. In June, 1915, these institutions offered degrees in forestry to 147 men.

Attention is called to the overstimulation of professional training and the underdevelopment of vocational instruction, even though in forestry scores of foremen, guards, and rangers are necessary for every professionally trained

forester, and to the rapidly decreasing demand in the past four years for professionally trained men. While more than 50 institutions have within the past 15 years developed more or less work in forestry education below the grade of full professional training, it is stated that it has largely been without definite aim and poorly suited to the real needs of the country, very little of it even approaching the requirements of the ideal vocational school. In order to best conserve the purposes of forestry education in the United States the author thinks at least two-thirds of the money now expended on professional training could be better spent in the instruction of the public through the organization of institutes, field demonstrations, and similar methods that have been found so effective in agriculture, and in the organization of vocational schools for the training of young men in the art of forestry practice. It is his opinion that the progress made in the actual conduct of forestry operations in the woods must center in a large number with some training rather than full professional training, whose knowledge of forestry is chiefly confined to the art of forestry so far as it concerns their own locality, and who do not look for and should not expect a wage beyond which the operations justify.

A bibliography of forestry education is appended.

### MISCELLANEOUS.

**Thirty-ninth Annual Report of Connecticut State Station, 1915** (*Connecticut State Sta. Rpt. 1915, pt. 6, pp. XVI*).—This contains the organization list, a report of the board of control, and a financial statement for the fiscal year ended September 30, 1915.

**Annual Report of Nevada Station, 1915** (*Nevada Sta. Rpt. 1915, pp. 56, figs. 5*).—This contains the organization list, a report of the director on the work of the station, departmental reports, the experimental work in which is for the most part abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1915.

**Report of the Canada Experimental Farms, 1915** (*Canada Expt. Farms Rpts. 1915, pp. 1229, pls. 97*).—Volume 1 of this report contains the report of the director, including general notes, meteorological data, and synopses of the work of the various divisions, branch farms, stations and substations, and reports of the divisions of chemistry, field husbandry, and animal husbandry. Volume 2 contains reports from the divisions of horticulture, cereals, botany, bees, forage plants, poultry, and tobacco. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Monthly Bulletin of the Ohio Experiment Station** (*Mo. Bul. Ohio Sta., 1 (1916), No. 9, pp. 257-288, figs. 19*).—This contains several articles abstracted elsewhere in this issue; Three Important Internal Parasites of Sheep, by D. C. Mote, an abridgment of Bulletin 280 (E. S. R., 33, p. 279); and the following special articles: The use of the Score Card in Potato Judging, by S. N. Green; and Identification of Clover Teaf Tyer, by H. A. Gossard.

**Monthly bulletin of the Western Washington Substation** (*Washington Sta., West. Wash. Sta., Mo. Bul., 4 (1916), No. 6, pp. 20, figs. 2*).—This number contains brief articles on the following subjects: Canning Vegetables by the Cold-pack Process, by T. J. Newbill; Strawberries in Western Washington, by J. L. Stahl; Seeding and Management of Grass Land, by E. B. Stookey; and The Shoup Oat Sprouter, by Mr. and Mrs. G. R. Shoup (see p. 75).

**A handy field and laboratory binocular magnifier**, R. S. WOGLUM (*Jour. Econ. Ent., 9 (1916), No. 3, pp. 370, 371, fig. 1*).

## NOTES.

---

**Florida University and Station.**—O. W. Weaver has been appointed agricultural editor.

**Indiana Station.**—D. F. Mattson has resigned as assistant in creamery inspection to become inspector in market milk work at the University of Wisconsin, vice A. C. Baer, whose resignation has been previously noted.

**Maine Station.**—William R. Rich and Walter W. Webber, assistant chemists, have resigned to accept commercial positions. Elmer R. Tobey, formerly assistant chemist, has been reappointed to that position.

**Maryland College.**—Plans have been approved by the building committee for the new agricultural building, for which \$175,000 was appropriated by the last legislature. A three-story and basement structure, with a front wing 200 by 68 feet, connected by an enclosed bridge with an auditorium seating about 1,000 people, and this in turn connected with a rear wing of the same dimensions as the front, is contemplated. The front wing is to be used for offices and classrooms and the rear wing for stock judging and exhibitions and experimental work. It is hoped that the structure will be ready for use next fall.

Evening courses in various branches of agriculture are being offered, including special work in bee keeping, poultry raising, and fruit growing for suburban residents of Washington, D. C. College credit is to be given for these courses so far as practicable, with a system of certificates showing all work completed.

**Massachusetts College and Station.**—Rudolph W. Ruprecht, Ph. D., resigned as assistant chemist in the station December 1, 1916, to engage in commercial work. Arnold P. Sturtevant, Ph. D., assistant in veterinary science, resigned on the same date to accept a position in the U. S. Department of Agriculture, and has been succeeded by Dr. A. C. Edwards, whose time will be divided equally between the college and station. John B. Smith has been appointed assistant chemist in the section of foods and feeding, beginning October 1, 1916, and Miss Grace B. Nutting, curator in the department of botany, beginning January 1.

**Minnesota University.**—Dr. George E. Vincent has resigned as president to become head of the Rockefeller Foundation, beginning May 15.

Harvey M. Bush, farmers' club specialist in the extension department, died December 15, 1916, at the age of 33 years.

The school of agriculture at Crookston is offering two scholarships at \$100 each and 10 at \$125 each, four of the latter scholarships being awarded as prizes to prospective students in contests in corn and potato growing, bread making, and pig raising. A special loan fund for students is also provided by a committee of citizens of Crookston.

**Missouri University and Station.**—E. R. Spence, extension assistant in veterinary science, has resigned to become superintendent of live-stock experiments at the Texas Station, and has been succeeded by Dr. John S. McDaniel, previously assistant professor of veterinary science in the Michigan College.

Other recent appointments include F. C. Fenton, previously extension assistant in agricultural engineering in the Iowa College, as extension assistant professor of agricultural engineering, and Mark J. Smith, previously assistant animal husbandman in the Kentucky Station, as extension instructor in animal husbandry.

**Montana Station.**—R. A. Studhalter, research fellow in the Missouri Botanical Garden, has been appointed assistant in botany and bacteriology.

**Nebraska University and Station.**—H. D. Landis, of Seward, has been elected to the board of regents, succeeding W. G. Whitmore. P. L. Hall has been reelected to the board.

C. B. Lee has resigned as professor of animal husbandry and animal husbandman to accept a commercial position, this taking effect December 1, 1916.

**New Hampshire College and Station.**—W. L. Doran, graduate assistant in botany at the Massachusetts College, has been appointed instructor of botany and assistant botanist.

**New Mexico College and Station.**—F. W. Christensen has resigned as nutrition chemist to become professor of animal nutrition at the North Dakota College, and has been succeeded by J. D. Hungerford. C. I. Depuy, of the Forest Service of the U. S. Department of Agriculture, has been appointed extension secretary, vice C. P. Wilson resigned November 15, 1916, to become secretary and editor for the station.

**North Carolina College.**—The division of home economics reports that 3,731 girls and 2,864 women, engaged in canning work in 44 counties, have filled a total of 680,551 containers at a profit of \$88,383.96. Twenty-seven scholarships have also been awarded in schools and colleges and 105 girls are paying their way either wholly or in part through their canning club work. The girls have also been active in making caps and dresses during the winter months and in starting winter gardens, which are a new thing for the South.

Twenty-five dairy schools have recently been held in the western part of North Carolina by members of the college staff and others are being arranged for.

**Ohio State University.**—P. B. Potter has been appointed instructor in agricultural engineering.

**Oregon College and Station.**—At the Third Annual Horticultural Show, held November 3 and 4, 1916, a 40 by 60 foot floor map of the United States, laid in green moss with the State boundaries marked in gray moss, was used to give a graphic representation of the pomological products of each State. Apples from 30 States were exhibited in variety groups, showing variations due to the soil and climatic conditions where grown. Competitive exhibits of fruits, grown by graduates of the college and by students now in attendance, were also shown. In the vegetable garden section, broccoli, Oregon's new \$25,000 winter crop, was given special prominence, while chrysanthemums formed the main feature of the floral display. The entire show was staged in a replica of the Tudor Gardens of England.

The annual winter short course began January 8 and closed February 2. One of its unique features was an apple packing school to instruct orchardists who will make their first commercial shipments of apples this year. A considerable number of new commercial orchards will come into bearing this season for which no expert packing help may be available.

The First Annual Northwest Grain Convention was held at the college January 3 to 5 in connection with the farmers' and homemakers' week. The bulk handling of grain was the special subject considered, farmers, dealers, shippers, and transportation men participating in the discussion.

A farm engine exhibit and demonstration was held by the farm mechanics department during the first two weeks of January.

A. L. Lovett, acting entomologist and associate professor of entomology, has been appointed entomologist with the rank of professor. G. R. Hyslop has been appointed collaborator in charge of the seed-testing laboratory, conducted jointly by the college and the U. S. Department of Agriculture, with Miss Norma Waddell as the official seed tester.

**Pennsylvania College and Station.**—I. D. Wilson, D. V. M., has been appointed instructor and assistant in animal husbandry, G. A. Meckstroth assistant in botany, L. P. McCann assistant in animal husbandry, and A. L. Beam instructor and assistant in dairy husbandry.

**Pennsylvania Institute of Animal Nutrition.**—W. H. Matthews, a 1916 graduate in agriculture of the college, has been appointed assistant.

**Porto Rico College.**—A revised course of study has been authorized by the chancellor of the university. This consists of a four years' subcollegiate course which provides sufficient technical work so that the collegiate work can be completed in three years. It is thus modeled on the general plan of polytechnic institutes that admit students to the sophomore classes of colleges. It is stated that the full course now ranks with that offered by the stronger American agricultural colleges. The enrollment has reached 225, a decided increase over previous years. Special opportunity is being offered students desiring to prepare themselves for work in tropical countries. The classes are conducted in English, but Spanish is usually quickly acquired as it is spoken by the students. Short courses are also being offered to rural teachers.

A new science building of 10 rooms has been completed and occupied. The new dairy laboratory is also completed.

Recent appointments include H. T. Cowles in horticulture, Dr. Jaime Bagué in animal husbandry, and Dr. R. I. Garton in zoology and entomology.

**Utah College and Station.**—Dr. E. G. Titus, professor of entomology and entomologist, has resigned to accept a position with the U. S. Department of Agriculture in connection with its sugar-beet investigations in Utah and Idaho.

**National Congress of Horticulture.**—Following a meeting called by the American Pomological Society, a National Congress of Horticulture was organized at Washington, D. C., in November, 1916, to serve as a central clearing house of horticultural interests. Active membership is to consist of delegates appointed by affiliated horticultural organizations on the basis of membership, and it is hoped thus to enroll representatives of from 50,000 to 60,000 members.

E. R. Lake, of the Bureau of Plant Industry of this Department, has been chosen secretary of the new organization.

**Necrology.**—J. Wrightson, president of the college of agriculture at Downton from 1880 to 1906, honorary professor of agriculture in the Royal Agricultural College at Cirencester, and professor of agriculture and agricultural chemistry at the Royal College of Science at South Kensington from 1882 to 1898, died November 30, 1916.

Captain R. W. Nichols, assistant in milling and baking at the central station of the Canadian Experimental Farms, was killed in the European War October 23, 1916, at the age of 31 years.

George G. White, professor of farm management and rural economics at the Manitoba Agricultural College, was killed October 10, 1916, while operating a farm tractor.

Agar agar for bacteriological use, Noyes.....	131

## FIELD CROPS.

[Field crop experiments].....	131
[Work with field crops at the Belle Fourche Farm in 1915], Aune.....	131
[Work with field crops on the Huntley Farm in 1915], Hansen.....	132
[Work with field crops on the Scottsbluff Farm in 1915], Knorr.....	132
[Work with field crops on the Truckee-Carson Farm in 1915], Headley.....	133
[Work with field crops on the Yuma Farm in 1915], Blair.....	133
Cereal experiments on the Cheyenne Experiment Farm, Jones.....	133
Effect of different nitrogenous fertilizers on oats and mustard, Hiltner.....	134
Anomalous endosperm development in maize and bud sports, Emerson.....	134
Yields of different varieties of corn in Illinois, Burlison and Allyn.....	135
Variety tests of corn, Hutchison, Evans, Hackleman, and McDonald.....	135
Study of the root system of flax, Modestov.....	135
[The effect of freezing on flax seed], Shulov and Morozov.....	136
Changes in specific gravity of potato tubers during the rest period, Széll.....	136
[Variety tests with potatoes], Gaskill.....	136
Commercial handling, grading, and marketing of potatoes, More and Dorland..	136
The possibilities of sugar beet culture in Washington, Cardiff.....	137
Experiments with Marquis wheat, Ball and Clark.....	137

## HORTICULTURE.

Encyclopedia of horticulture, compiled by Pucci.....	137
[Horticultural investigations on Yuma Reclamation Project in 1915], Blair...]	137
[Experiments with vegetables on the Truckee-Carson Project], Headley.....]	137
Manual for the raising of garden seed, Dæhnefeldt.....	137
[Report of] the asparagus substation, Concord, Brooks.....	137
De Vriesian mutation in the garden bean, <i>Phaseolus vulgaris</i> , Harris.....	138
Marketing and distribution of western muskmelons, Schleussner and Kitchen.....	138
The melons on the market in Paris, Buisson.....	138
[Some results of horticultural investigations].....	138
[Orchard trees and small fruits on Huntley Reclamation Project], Hansen.....]	140
Modern propagation of tree fruits, Brown.....	140
Some figures on the cost of bringing orchards into bearing.....	140
Some improvements in the packing and transport of fruit in India, Howard.....	140
Notes on Pomaceæ of upper South Carolina, Ashe.....	140
The pollination of the pomaceous fruits, III, Kraus and Ralston.....	140
The fruiting of trees in consecutive seasons, Pickering.....	140
Peach growing in Ontario, Clement and Harris.....	140
The persimmon in California, Fujii.....	141
State bog report, Franklin.....	141
Is the hybrid origin of the loganberry a myth?.....	141
Methods of reproducing grapes by long cuttings and short cuttings, Ricome.....	141
Some recent operations and experiments with bud variations, Shamel.....	141
Pruning the Washington naval orange, Hodgson.....	141
Report on manurial experiments.....	141
[Cacao experiments, 1914-15], De Vertuil.....	141
Cacao, van der Laat.....	141
[Experiments with coffee in Surinam], Van Drent.....	141
The cultivation and preparation of coffee for the market, Ugarte.....	142
New and successful method of rooting date palm offshoots, Coit.....	142
Colonial plants.—Perfume, tincture, and tannin plants, and tobacco, Jumelle.....	142
Colonial plants.—Industrial plants, Jumelle.....	142
Sources of supply of hazelnuts.....	142

	Page.
Iris breeding .....	142
My garden, Wilder .....	142
My garden in spring, Bowles.....	142
My garden in summer, Bowles.....	143
My garden in autumn and winter, Bowles.....	143
Beautifying the rural home, Keyser and Welch.....	143

## FORESTRY.

British forestry, Stebbing.....	143
Forest problems and economic development in South America, Zon.....	143
South American forests, Curran.....	143
[Trees and shrubs on the Belle Fourche Reclamation Project], Aune.....	143
Tree distribution under the Kinkaid Act, 1911.....	143
Forest Service silviculture plans, Woolsey, jr.....	143
Notes on forest cover and snow retention in Colorado, Betts.....	143
Evaporation and soil moisture in relation to plant succession, Korstian.....	144
Silvical notes on western larch, Larsen.....	144
Slash pine, an important second-growth tree, Mattoon.....	144
The natural root grafting of conifers, Newins.....	144
Chemistry as an aid in the identification of species, Schorger.....	144
Comparative test of Klausner and Forest Service standard hypsometers, Noyes.....	144
Utilization and round-edge lumber, Fisher.....	145
The utilization of a tropical forest, Ahern.....	145

## DISEASES OF PLANTS.

Department of botany, Osmun.....	145
Five undescribed species of <i>Ravenelia</i> , Long.....	145
<i>Rhizoctonia solani</i> in relation to "Mopopilz" and "Vermehrungspilz," Duggar.....	145
Cereal disease resistance.....	145
Rye smut, Stakman and Levine.....	146
Determination of ustilaginous spores in flour, bran, and cereals, Bredemann.....	146
The quantitative determination of smut spores in bran, Bredemann.....	146
The Texas root rot fungus and its conidial stage, Duggar.....	146
Spongospora on roots of potato and 7 other new hosts, Melhus and Rosenbaum.....	146
Meteorology and late blight of potatoes, Orton.....	146
A <i>Fusarium</i> tuber and stem rot of potato, Haskell.....	146
Crop yield, tuber color, and leaf roll of potato, Ahr et al.....	147
Field studies on the <i>Rhizoctonia</i> of the potato, Cook and Lint.....	147
The effect of Bordeaux mixture on the potato plant, Lutman.....	147
Biochemical study of root rot in sugar beets, Bodnar.....	147
Fruit tree diseases of southern Ontario, McCubbin.....	147
Temperature relations of apple rot fungi, Brooks and Cooley.....	147
Black root rot of apple, Fulton and Cromwell.....	147
Effects of <i>Sphxropsis malorum</i> on composition of the apple, Culpepper et al.....	148
Blister spot of apples, Rose.....	148
Flower wilt and young fruit rot of apple by <i>Sclerotinia mali</i> n. sp., Takahashi.....	148
Apple scald, Brooks and Cooley.....	148
Brown blotch of the pear, Martin.....	149
The parasitism of <i>Valsa leucostoma</i> , Walton and Babcock.....	149
Investigations of leaf spot of cherries and plums in Wisconsin, Keitt.....	149
The Surinam witch-broom disease of cacao, Rorer.....	149
Chestnut tree disease in Ardèche, Trabut.....	149
Influence of tannin content of host on <i>Endothia parasitica</i> , Cook and Wilson.....	149
The chestnut blight and the white pine blister rust, Brooks.....	150
Eelworm parasite of plants, Frandsen.....	150
Injuries to plants kept in rooms, Sorauer.....	150

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

Zoological record, Sharp.....	151
Game laws for 1916, Palmer et al.....	151
Second annual report of bird counts in the United States, Cooke.....	151
A field ornithology of the birds of eastern North America, Maynard.....	151
Common birds of southeastern United States and agriculture, Beal et al.....	151
How to attract birds in northwestern United States, McAtee.....	151
Birds in their relations to man, Weed and Dearborn.....	151

	Page.
A new air-conditioning apparatus, Dean and Nabours.....	152
Effects of nicotin as an insecticide, McIndoo.....	152
Insects injurious to alfalfa, Dean.....	152
Insects attacking onions, Ballou.....	152
The more important greenhouse insects, Weiss.....	152
The animal parasites of man, Fantham, Stephens, and Theobald.....	152
New Jersey's insects, Weiss.....	152
Reports of the government entomologist, 1915 and 1916, Mason.....	153
Some new entomogenous fungi in St. Vincent, Nowell.....	153
The lesser migratory locust ( <i>Melanoplus atlantis</i> ), Herrick and Hadley, jr.....	153
The sugar-beet thrips, White.....	153
The bedbug, Marlatt.....	153
The chinch bug outbreak of 1910 to 1915, Forbes.....	153
The false chinch bug and measures for controlling it, Milliken.....	154
Are scales becoming resistant to fumigation? Quayle.....	154
Root louse control, Hansen.....	154
The grape leaf-folder, Strauss.....	155
<i>Tinea cloacella</i> as a mushroom pest, Krause.....	156
The destruction of fly larvæ in horse manure, Cook and Hutchison.....	156
Response of the house fly to ammonia and other substances, Richardson.....	156
Flies and their relation to diarrhea and dysentery, Morison and Keyworth.....	156
[Report of the] department of entomology, Fernald.....	156
The soy bean stem borer, Dutt.....	157
Rhynchophora or weevils of northeastern America, Blatchley and Leng.....	157
The cottonwood borer, Milliken.....	157
The southern corn billbug, Metcalf.....	157
The banana weevil, Ballou.....	158
Productive bee keeping, Pellett.....	158
Bees and how to keep them, Sladen.....	158
Fifteenth report of Illinois State Beekeepers' Association, compiled by Stone..	158
Rocky Mountain spotted fever.—Laboratory investigations of the virus, Fricks.	158

## FOODS—HUMAN NUTRITION.

The nutritive properties of corn, Hogan.....	158
The nutritive value of yeast, polished rice, and white bread, Funk et al.....	158
Rye flour and rye bread, Braun.....	159
Some tests of flour made from Egyptian wheats, Hughes.....	159
[Inspection of shellfish].....	159
Studies on growth.—III, Lard and butter fat in growth, Funk and Macallum..	160
Studies on growth.—IV, Action of yeast fractions, Funk and Macallum.....	160
Isolation of a growth-producing substance from sheep pancreas, Eddy.....	160
Study of dietary conditions bearing on growth in rats, Funk and Poklop.....	161
Dietetic deficiency, Green.....	161
Studies in creatin metabolism, I-IV, Underhill and Baumann.....	161
Output of urinary constituents as determined by diet, Underhill and Bogert..	162
Volume of urine in young healthy adults on constant diet, Addis and Watanabe.	163
The rate of urea excretion, I, Addis and Watanabe.....	163
The rate of urea excretion, II, Addis and Watanabe.....	163
Blood fat and sugar content of dogs given hydrazin, Underhill and Baumann..	164
The toxicity of carotin, Wells and Hedenburg.....	164
Clinical calorimetry, XVIII, Gephart et al.....	164

## ANIMAL PRODUCTION.

Meat situation in United States.—V, Methods and cost of marketing, Hall et al.	164
The marketing of live stock, Gaumnitz.....	166
On the general theory of multiple contingency, Pearson.....	166
Multiple frequency distributions with skew regression, Isserlis.....	166
Probable error of coefficient of contingency Young and Pearson.....	166
Novel properties of partial and multiple correlation coefficients, Pearson.....	166
Application of "goodness of fit" tables, Pearson.....	166
The "best" values of the constants in frequency distributions, Smith.....	167
Berseem as a forage plant, Piot.....	167
Silos and silage, Sheets.....	167
Pea-cannery refuse, Rosby.....	167

	Page.
Commercial feeding stuffs and registrations for 1916, Cathcart et al.....	167
[Animal husbandry work].....	167
Inheritance of color and horns in blue-gray cattle, Lloyd-Jones and Evvard...	168
Feeding range steers, Foster and Simpson.....	168
Pasturing sheep on alfalfa, Aune.....	169
Sheep feeding experiment.....	169
[Feeding experiments with lambs].....	170
The use of hogs in disposing of crops, Knorr.....	170
[Pasturing alfalfa and corn with hogs], Aune.....	171
[Pasturing alfalfa and corn with hogs], Hansen.....	171
[Feeding experiments with pigs], Thompson.....	171
Effect upon work horses of alfalfa hay cut at different stages of growth.....	171
Growing draft colts, McCampbell.....	172
Philippine horses, Mackie.....	172
[Poultry investigations], Dougherty.....	172
[Poultry investigations].....	173

## DAIRY FARMING—DAIRYING.

[Dairy husbandry studies], Woll.....	173
Carrying capacity [of irrigated pastures], Hansen.....	173
The cost of producing goat milk, Voorhies.....	173
The relation of the quality of proteins to milk production, Hart et al.....	174
Cooling hot-bottled pasteurized milk by forced air, Ayers et al.....	174
Grading and labeling of milk and cream.....	176
Butter making, Davis.....	176
Cheese making, Baird.....	176
Manufacture of cheeses with definite fat content in dry substance, Windisch...	176
The milking machine a source of bacterial contamination of milk, Ruediger...	177
Ice cream, Davis.....	177

## VETERINARY MEDICINE.

Veterinary bacteriology, Buchanan and Murray.....	177
Bacteriology.—General, pathological, and intestinal, Kendall.....	177
A text-book upon the pathogenic bacteria and protozoa, McFarland.....	177
Comparative resistance of bacteria and tissues to germicides, Lambert.....	177
The use of sugar as a dressing in veterinary surgery, Bussano.....	178
Colloidal chemistry and immunology, von Krogh.....	178
An improved method for the concentration of antitoxic sera, Homer.....	178
The refinement and concentration of antitoxins, Heinemann.....	179
Another poisonous Claviceps, Norton.....	179
Report of the veterinary director general for 1914, Torrance.....	179
Annual report of the veterinary service for the year 1914, Littlewood.....	180
Disinfection of tannery effluent containing anthrax spores, Wintersberger.....	180
The strength and composition of blackleg vaccines, Franklin and Haslam.....	180
The ophthalmic test for glanders, with a simplified procedure, Ferry.....	180
An atypical case of rinderpest in a carabao, Boynton.....	181
The prophylaxis of tetanus by antitoxic serum, Vaillard.....	181
Researches in trichinosis, Lintz.....	181
Complement fixation in tuberculosis, Corper.....	181
Studies in immunization against tuberculosis, von Ruck.....	182
Tuberculosis in Normandy, Fréger.....	182
Sheep diseases, Baker.....	182
Shoeing and balancing the light harness horse, Clark.....	182
The epidemiology of pectoral influenza of the horse, Mack.....	182
A tri-radial tapeworm ( <i>Anoplocephala perfoliata</i> ) from the horse, Meggitt.....	183
Diseases of the dog and their treatment, Müller and Class.....	183
Parasitological investigations.....	183

## RURAL ENGINEERING.

Annual report of the state engineer and surveyor of New York, 1914.....	183
The action of copper sulphate on the algae in drinking water, Bado.....	183
Chlorin treatment of water, Hilscher.....	183
Successful sewage disposal by broad irrigation, Bartlett.....	183

	Page.
Disposal of sewage from country houses, institutions, and clubs, Hansen.....	184
Double tank proposed for residential sewage plants, Coulter.....	184
Conveyance of water in open channels on the farm .....	184
Surface water supply of North Atlantic slope drainage basins, 1914.....	184
Supplement to report of state engineer and surveyor of New York, 1914.....	184
Oregon's opportunity in national preparedness, Lewis et al.....	184
Rainfall and agricultural power use, Shaw.....	184
Description of water wheel at Kudarangan Agricultural School, Haley .....	185
A complete method for the classification of irrigable lands, Peters.....	185
Official proceedings of sixth National Drainage Congress at Cairo, Illinois.....	186
Flood control and reclamation in California, McClatchy.....	186
Reclamation of the Worden tract, Hansen.....	186
The experiment farm drainage system, Headley.....	186
Suggestions for organization and financing of drainage projects, McCrory.....	187
Proceedings of second Good Roads Institute, compiled by Pratt and Berry....	187
[Road laws of the State of Kentucky].....	187
Economic surveys of county highway improvement, Pennybacker and Eldridge.	187
Bituminous macadam and bituminous concrete pavements, Blanchard.....	188
Brick laid directly on concrete base, Edwards.....	188
Distribution of traffic on a rectangular system of roads analyzed, James.....	188
Progress of experiments in dust prevention and road preservation, 1915.....	188
Road dust preventives: References to books and magazine articles.....	188
Concrete construction for rural communities, Seaton.....	188
Official tests of mechanical cultivation.....	189
Official tests of mechanical cultivation.....	189
Dairy barn construction, Higgins and Scoates.....	190
Building instructions for homemade silos, Oliver.....	190
Poultry houses, Peterson.....	190
A farmer's poultry house, Halpin and Schindler.....	190
A dual-purpose poultry house, Hadlington.....	190

## RURAL ECONOMICS.

Successful farm organization, Johnson.....	190
Farming on the cut-over lands of Michigan, Wisconsin, and Minnesota, McDowell and Walker.....	190
Management of muck-land farms in Indiana and Michigan, Smalley.....	191
Cost accounts on some New York farms, Ladd.....	191
Cotton ginning information for farmers, Taylor et al.....	191
Community organization for promoting the production of swine, Starr.....	192
[Studies in agricultural economics], Cance.....	192
A survey of typical cooperative stores in the United States, Bexell et al.....	192
Rural clubs in Wisconsin, Galpin and Sawtelle.....	192
Monthly crop report.....	193

## AGRICULTURAL EDUCATION.

Agricultural education, Waters.....	193
Progress of elementary agricultural education in Nova Scotia, De Wolfe.....	193
The efficient country school, Johnson.....	194
Applied science as the basis of the girl's education, Severy.....	194
Special science for girls in the rural schools, Twiss.....	194
Home economics applied to life, Van Rensselaer.....	194
Project teaching, Randall.....	194
Judging the dairy cow in secondary schools, Barrows and Davis.....	195
Proceedings of Association of Farmers' Institute Workers, edited by Taft.....	195

## MISCELLANEOUS.

Annual Report of California Station, 1916.....	195
Report of Kansas Station, 1915.....	195
Twenty-eighth Annual Report of Massachusetts Station, 1915.....	195
Thirty-fifth Annual Report of Ohio Station, 1916.....	195
Monthly bulletin of the Western Washington Substation.....	195

## LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	<i>U. S. Department of Agriculture.</i>
California Station:	Jour. Agr. Research, vol. 7:
An. Rpt. 1916.....	No. 1, Oct. 2, 1916.....
138, 170, 171, 172, 173, 176, 177, 195	No. 2, Oct. 9, 1916.....
Illinois Station:	No. 3, Oct. 16, 1916.....
Bul. 191, Aug., 1916.....	Bul. 393, Economic Surveys of
Circ. 189, Aug., 1916.....	County Highway Improvement,
Indiana Station:	J. E. Pennybacker and M. O.
Circ. 54, May, 1916.....	Eldridge.....
Iowa Station:	Bul. 394, A Survey of Typical Co-
Research Bul. 30, Feb., 1916.	operative Stores in the United
Kansas Station:	States, J. A. Bexell, H. Mac-
Bul. 211, Jan., 1916.....	Pherson, and W. H. Kerr.....
An. Rpt. 1915.....	Bul. 396, Second Annual Report of
145, 152, 167, 169, 171, 172, 183, 195	Bird Counts in the United States,
Louisiana Stations:	with Discussion of Results, W.
Bul. 157, Aug., 1916.....	W. Cooke.....
Maine Station:	Bul. 400, Experiments with Mar-
Off. Insp. 78, June, 1916.....	quis Wheat, C. R. Ball and J. A.
Massachusetts Station:	Clark.....
An. Rpt. 1915, pts. 1 and 2....	Bul. 401, Marketing and Distribu-
136, 137, 145, 156, 173, 192, 195	tion of Western Muskmelons
Minnesota Station:	in 1915, O. W. Schleussner and
Bul. 160, Aug., 1916.....	C. W. Kitchen.....
Missouri Station:	Bul. 407, Progress Reports of Ex-
Bul. 142, June, 1916.....	periments in Dust Prevention
Bul. 143, July, 1916.....	and Road Preservation, 1915....
New Jersey Stations:	Bul. 408, Experiments During 1915
Bul. 291, Feb. 1, 1916.....	in the Destruction of Fly Larvæ
Bul. 292, Feb. 1, 1916.....	in Horse Manure, F. C. Cook and
Bul. 295, May 27, 1916.....	R. H. Hutchison.....
Bul. 296, May 31, 1916.....	Bul. 419, The Grape Leaf-folder,
New Mexico Station:	J. F. Strauss.....
Bul. 101, Mar., 1916.....	Bul. 420, Cooling Hot-bottled Pas-
New York Cornell Station:	teurized Milk by Forced Air,
Bul. 377, June, 1916.....	S. H. Ayers, J. T. Bowen, and
Bul. 378, July, 1916.....	W. T. Johnson, jr.....
Mem. 9, July, 1916.....	Bul. 421, The Sugar-beet Thrips,
North Dakota Station:	W. H. White.....
Circ. 14, Aug., 1916.....	Bul. 424, The Cottonwood Borer,
Ohio Station:	F. B. Milliken.....
Bul. 300 (Thirty-fifth An. Rpt.	Bul. 425, Farming on the Cut-over
1916), June, 1916.....	Lands of Michigan, Wisconsin,
Oregon Station:	and Minnesota. J. C. McDowell
Bul. 138, May, 1916.....	and W. B. Walker.....
South Carolina Station:	Bul. 430, Cereal Experiments on
Bul. 187, Sept., 1916.....	the Cheyenne Experiment Farm,
Utah Station:	Archer, Wyo., J. W. Jones.....
Bul. 145, Sept., 1916.....	Bul. 434, Judging the Dairy Cow
Washington Station:	as a Subject of Instruction in
Popular Bul. 105, Aug., 1916..	Secondary Schools, H. P. Bar-
West. Wash. Sta. Mo. Bul.,	rows and H. P. Davis.....
vol. 4, No. 7, Oct., 1916....	Bul. 441, The Action of Manganese
West Virginia Station:	Under Acid and Neutral Soil
Bul. 157, July, 1916.....	Conditions, J. J. Skinner and
Wisconsin Station:	F. R. Reid.....
Bul. 271, Aug., 1916.....

# EXPERIMENT STATION RECORD.

VOL. 36.

FEBRUARY, 1917.

No. 2.

The need of special training for the men who conduct the experimental and research work of the experiment stations has been felt almost from the first. The early work of the stations was relatively simple and fewer lines of investigation were maintained. The agricultural colleges were looked to mainly to supply the necessary men and the requisite training. It soon became apparent, however, that the courses of study in agricultural colleges did not at that time supply the whole need. These courses were necessarily quite general and were intended more especially to make farmers rather than investigators. They supplied a general knowledge of the theory and principles but rarely gave opportunity for contact or experience with research.

From the first the stations themselves have been a large factor in training men for the special work of agricultural investigation. They have furnished not only a stimulus to special preparation, but an opportunity for acquiring experience through a sort of apprenticeship. To some extent they have trained their own men. But as time has passed this too has been found inadequate to the needs in many lines. The work of the stations has become more technical and serious, and they need for it men already well equipped and with a broad outlook.

The making of an effective research man or a constructive and original experimenter is a longer and far more difficult process than making a bachelor of arts or of science. The requirements start with the man himself, his temperament, his capacity for right thinking, his ability to receive the impression of high ideals and acquire lofty standards, and his love of truth. There must be a foundation to build upon. If a sifting process could start at this point it would save some time, expense, and disappointment, but such a sifting is only partially possible; largely the result must be worked out by experience.

Whether a man is preparing for an experimental or research career he needs some hard, rigid training that will bring him up against the real meaning of science. He must learn the elements that go to make up a fact, and how to attest its value. He must get not only a broad

foundation of information but he must acquire an attitude and a method. This is often much harder than learning facts and principles, and it is where some men prove lacking.

The graduate student often feels that he needs especially a larger fund of information to make him efficient and resourceful, and sets out to get knowledge. He needs not only this but to get understanding, to develop an inquiring attitude, a vision, a discriminating criticism. He needs to come directly and intimately into contact with research in its higher restricted sense, as an active participant. This teaches him its real responsibilities and its exact nature. For this purpose graduate study in some of the older exact sciences is especially advantageous, because the methods are better worked out and the requirements usually more severe. Graduate work in some of the divisions of agriculture may not necessarily convey a deep impression of the spirit and feeling of science. Whether it does or not depends somewhat upon the teacher. The tasks and problems set are often comparatively simple in their scientific aspects, although they may be laborious and difficult in other respects.

The means of training and of securing competent persons for the work of the stations continues to be a live question. It was one of the topics before the last convention of the Association of American Agricultural Colleges and Experiment Stations, and was discussed in two important papers in a joint meeting of the sections of college work and experiment station work. The discussion related specifically to the encouragement of advanced training by offering employment to a limited number of graduate students as part-time research assistants in the station. Such an arrangement has been put into effect at a number of the stations, and especially at the New Jersey Station it has constituted a definite policy and a means of providing assistance.

In discussing this plan from the standpoint of advantage to the station, Dr. J. G. Lipman described its operation at his institution. The station was led into the plan partly from considerations of economy, feeling that it offered a means of securing cheap assistance without lessening the effectiveness and value of the research, and at the same time would stimulate advanced study.

The present tendency to organize station work on the project basis has been found to favor the use of graduate students as research assistants. Thus research problems of considerable magnitude may be divided so as to assign different parts to assistants working under close supervision; and "an experienced investigator may so arrange his research problems as to permit the utilization of the services of beginners in research, provided they possess the right temperament and training." While it is not the practice to place

untrained graduate assistants directly in charge of important phases, it is found that they may be satisfactorily assigned to many duties in connection with such projects, often of a more or less routine nature at the outset, and as they develop in ability and initiative more responsible and technical parts of the work may be turned over to them. Ultimately a phase of a project may serve as the subject of a master's or doctor's thesis.

Dr. Lipman recognized that the system might break down if the research problem were not carefully analyzed and so subdivided as to make portions of it safe to entrust to research students. Success also depends on securing young men who possess not alone adequate technical training but temperamental and other qualities fundamental to the making of good investigators.

The New Jersey Station at present regularly employs nine research assistants on a half-time basis, the remainder of the time being devoted to study. Naturally a longer time is required to secure a degree than if full time were devoted to study, but the salary paid such assistants is found to offset the time element with a considerable number of men. The problems assigned these assistants by the station are as far as possible correlated with their major studies as graduate students in the college.

Since the adoption of this plan it is felt at the station that its research work has improved in quality and to some extent increased in amount, and at the same time there has been a gain to a number of young men who are preparing themselves for service in agricultural investigation.

An interesting turn to the discussion was given by Dr. L. R. Jones of Wisconsin, who considered the matter from the standpoint of the teacher and the student. He held the two most important functions of the teacher in relation to graduate students to be "aiding men wisely to choose their own profession, and properly placing within reach of the men the means of their education." He felt there were certain dangers in the research fellowship plan, owing to the effect which financial help might have on the student in reaching a choice.

"We may all agree that any such help that makes possible the high training of our best types of research students is desirable. But do we not need to recognize that in this or any other financial offering which influences immature students to start upon research as a profession lurks the danger of attracting the weaker more than the stronger?" While zealously searching for the right man, therefore, equal care should be exercised "not to tempt or bribe the unfit."

Considering further the best interests of the student, Dr. Jones pointed to the advantage of a change of location from his Alma Mater to another institution for his graduate study, especially after

the first year or so of advanced work. Among the benefits of such a migration were mentioned "a completely changed environment, a fresh library, a different laboratory, a new set of scientific associations, another departmental leader and adviser."

Professor Jones recognized the very marked advance in facilities for graduate study at many of our American institutions, and expressed the belief that "hereafter no American student, at least in the sciences fundamental to agriculture, need leave America in order to find the best in graduate opportunity as represented in library, laboratory, or personal leadership." But he referred to a certain provincialism in this country as compared with European institutions, which tends to accentuate the advantage of migration to another institution. Loyalty to Alma Mater is often responsible for a feeling that it affords advantages at least equal if not superior to those to be had elsewhere; and this, together with the rapid growth of the agricultural colleges, has frequently resulted in a kind of "inbreeding" which is not advantageous to a broad outlook and proper perspective.

These things have affected the easy and natural migration of graduate students, which the aid of teachers is needed to overcome. Dr. Jones felt that "practically every candidate for the doctor's degree who is being held by an institution for three or more years of resident work should be expected to spend at least one semester at another institution, and perhaps two would be better." Until such interchange becomes as much a custom here as it is among European students, he urged that teachers and administrative officers should stimulate it by advice and requirement.

While these views are not necessarily in conflict with the plan of employing research assistants in the station with opportunity for graduate study, it was suggested that in practice the best local men would often be selected for such employment, which in the end would be disadvantageous to the student if continued throughout the period of graduate study. "Our agricultural professions need recruits trained in the broadest and best way, and such a method fails to meet these standards."

The advantages from such intermigration of research students between different institutions are manifest—the coming into a new environment with somewhat different standards or points of view, a new laboratory routine or method of presentation, an association with men from other institutions in different parts of the country, all have a tendency to stimulate, to arouse, to develop, and to liberalize the student in his attitude toward science. So far from being an evidence of lack of application and diletantism, it is an evidence of a desire to get not only the best that is to be had in science

but a broader understanding of teaching and research and a wider horizon.

Perhaps it may transpire that the plan of employing graduate students as part-time research assistants may tend to promote migration rather than otherwise, by affording the means which will enable it. The added expense of going to another institution might often deter students of limited means from following that course, and result either in their remaining at their home college or having to be content with a shorter period of study. With proper helpful guidance on the part of the teacher, therefore, the advantage which Dr. Lipman claims, to the student as well as to the institution, may be realized and the dangers which Dr. Jones has so pertinently pointed out be avoided.

Evidently the stations can not depend too extensively on assistants of this type, and provision will still need to be made which will meet the special requirements of the work they have in hand. The graduate students will therefore in a measure supplement the regular forces of the stations, providing relatively cheap assistance in the technical features.

Many of the stations have, of late especially, felt the necessity of giving attention to simulating advanced study on the part of their assistants and making some form of provision or requirement for it. It has become a well established practice at several stations to require young men entering the work to take advanced study from time to time as a prerequisite to advancement. Others, while exacting this requirement, have gone so far as to prohibit the taking up of graduate work at the local institution while retaining their position in the station. This may be due to a disinclination to combine station service and graduate study, or to a belief that the student should go away for such study.

The plan has worked out somewhat differently at different stations, but in general the present tendency is to recognize the necessity for occasional furlough to take advanced work, in order that the enthusiasm and mental alertness of the investigator may not suffer from monotony and a stereotyped activity.

Most of the endowed universities and other institutions of higher learning now give credit for research work done on recognized projects at the experiment stations, some requiring only a single year's residence at the institution for a doctor's degree. Many of the younger station men are availing themselves of this opportunity, and the number is increasing from year to year. The plan has been found to work to the mutual advantage of both the station and the research workers. Several of the colleges have an arrangement for sabbatical leave, with part pay, for purposes of study. This is not

always recognized as a right but rather as a privilege, to be granted to workers in recognition of special merit or accomplishment.

An interesting modification of this plan has been recently put into operation at the Minnesota Station. It is announced that hereafter station workers will be on the same basis as teachers in the college with respect to vacation. Of the three months' vacation thus provided, it is required that one month be taken for rest and recuperation, while in the other two months the station men are expected to go to other institutions for advanced lectures, to observe new laboratory methods and practices, and in general to gain information and suggestion which will bear particularly on their own special lines of work. This liberal plan gives all men on the station staff, without regard to age, an annual opportunity of renewing their enthusiasm and acquiring the inspiration of new ideas which come with sojourn at another institution and intimate association with other workers.

At one of the New York meetings during the holidays reference was made to the relatively small part which physics has yet played in the study of problems in agricultural science. The laws of physics are of course applied by agricultural investigators as all science may be employed so far as it comes within the range of the investigator. In this way physics is borrowed to some extent by the workers in soils, in biology, and in other branches of science, who make limited excursions into the domain of that science for such aid and suggestion as they may be able to appropriate. But consciously physics as a science has done far less through its exponents to serve farming or influence investigation in it than many other branches of science.

Physicists have been busily engaged in working out the laws and problems of dead matter, the physical forces, the heavenly bodies, etc., but it is rare to find one who has brought his science to bear on the activities of the living organism. His special point of view and his intimate knowledge of the laws of matter have not been directed toward the problems met in agricultural science. There has been little attempt to relate research in physics to agricultural problems, and almost as little to employ it in agricultural inquiry, which has evidently escaped the physicist's notice.

Rarely also has the embryo agricultural investigator been led to select physics as a subject for graduate study, or one in which to perfect himself as an aid in his search for causes and explanations. This is probably due to the fact that the subject has not been opened up in its full agricultural importance, and physicists absorbed in other lines of interest have given little attention to elaborating and pointing out its fundamental bearing at many points. The field of the physicist with a distinct agricultural outlook and interest remains, therefore, an undeveloped one.

Apropos of these thoughts it is interesting to mention an instructive lecture on *The Living Plant as a Physical System*, recently delivered by Dr. Lyman J. Briggs of this Department. This was a remarkable address on account of the novelty of the subject and the new outlook it presented. It was highly suggestive of the advantage of the physicist's viewpoint in approaching and in attempting to explain phenomena in plant life connected with its physiological activity and its relations to its environment.

Dr. Briggs dealt especially with such functions as plant transpiration, efficiency in the use of water by different groups of plants, drought resistance, the rise of water in the plant, the assimilation of carbon dioxid, and other processes of growth. He illustrated some of these phenomena by experiments with physical apparatus, notably the theory upon which the rise of sap in trees depends, the action of the mechanism to prevent interference through air bubbles, etc. He discussed the mechanics of these processes, and the physical measurement of the plant's response to differences in environment. He showed how in many cases the vital activities of the plant follow quite closely established laws and principles in physics, and made it clear in how large degree the explanation of manifestations which are observed in practice and in scientific inquiry may with advantage be sought through that science.

Already the quantitative methods of physics and physical chemistry have begun to invade biological research, as Dr. Loeb recently explained. This marks a step in advance for it shows that zoologists and botanists have come to "grasp the fact that the progress of science depends upon the invention or application of such methods." So many of the processes of living as well as of dead matter rest upon physical laws and principles that there is reason to believe a much larger field is open to physics in agricultural investigation than is at present occupied. The employment of the science by specialists in it who are acquainted with agriculture and its problems would contribute a viewpoint and a method highly important and helpful. An intimate knowledge of it may supply a very material element of strength in the agricultural investigator.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

The physical properties of colloidal solutions, E. F. BURTON (*London and New York: Longmans, Green & Co., 1916, pp. VII+200, figs. 18*).—This volume discusses the physics of colloidal solutions under the following topics: Preparation and classification of colloidal solutions; the ultramicroscope; the Brownian movement; the optical properties of colloidal solutions; measurement of the sizes of ultramicroscopic particles; motion of colloidal particles in an electric field, cataphoresis; the coagulation of colloids; theory of the stability of colloids; and practical applications of the study of colloidal solutions. A bibliography of the literature cited is appended to each chapter.

The influence of ethyl alcohol and glycerol upon the rate of solution of casein by sodium hydroxid, T. B. ROBERTSON and K. MIYAKE (*Jour. Biol. Chem., 26 (1916), No. 1, pp. 129-142, figs. 4*).—The work reported has shown that both alcohol and glycerol retard the penetration of casein particles by 16/1,000-normal sodium hydroxid. The penetration formula (E. S. R., 35, p. 712) expresses the relationship between the quantity of casein dissolved and the time of stirring in all the glycerol-water mixtures studied, and in alcohol-water mixtures containing less than 4.5 or more than 7 molecules of alcohol.

Further considerations on the effect of the concentration of alcohol and glycerol are also set forth.

A comparative study of the behavior of purified proteins towards proteolytic enzymes, E. M. FRANKEL (*Jour. Biol. Chem., 26 (1916), No. 1, pp. 31-59, figs. 4*).—The experiments reported demonstrate that in pepsin-hydrochloric acid digestion pepsin is the effective agent, since hydrochloric acid, in the concentrations ordinarily employed, has very little proteolytic effect.

It is concluded that comparable results in proteolysis studies are to be obtained only when the substrates are in solution; otherwise deviations of from 10 to 15 per cent may be encountered in duplicate experiments. A parallelism in the cleavage curves of 13 proteins examined was observed, the cleavage being calculated as the ratio of amino nitrogen liberated at any one time to that obtained on total hydrolysis of the protein with strong acid. Pepsin-hydrochloric acid was found to liberate about 20 per cent of the total amino nitrogen of a protein in less than 100 hours. Trypsin acting on such partially digested proteins effects a cleavage of about 70 per cent, while its action on native proteins causes a cleavage of only about 50 per cent of the peptid linkages. Erepsin following the action of pepsin was found to be a very effective agent in causing the disruption of the protein molecule, about 85 per cent of the protein being cleaved in the experiments reported. By the successive action of pepsin, trypsin, and erepsin from about 85 to 90 per cent of the total amino nitrogen was found to be liberated in the protein studied.

The origin of the humin formed by the acid hydrolysis of proteins.—II, Hydrolysis in the presence of carbohydrates and of aldehydes, R. A. GORTNER (*Jour. Biol. Chem., 26 (1916), No. 1, pp. 177-204*).—Continuing the work

of Gortner and Blish, previously noted (E. S. R., 35, p. 311), the author at the Minnesota Experiment Station has found that the amount of ammonia nitrogen in a protein hydrolyzate is not significantly altered when hydrolysis is carried out in the presence of a quantity of carbohydrate equal to three times the weight of the protein material.

If the weight of carbohydrate material present greatly exceeds the amount of protein an accurate nitrogen distribution by Van Slyke's method can not be obtained. The amount of humin nitrogen is greatly increased by the presence of carbohydrate, probably because of both chemical and physical causes. Tryptophan can not be accurately estimated by hydrolyzing proteins in the presence of carbohydrates. When fibrin is hydrolyzed in the presence of furfural the humin nitrogen is greatly increased. This increase is deemed due not only to a chemical reaction in which certain amino acids combined with furfural, but also to adsorption or occlusion of other amino-acid nitrogen by the humin. When furfural is boiled with strong hydrochloric acid approximately 75 per cent by weight is converted into a black insoluble mass. It is suggested that perhaps the humin, "formed from carbohydrates by boiling with hydrochloric acid, is actually formed from furfural, which is in turn formed from the carbohydrate."

When fibrin is hydrolyzed in the presence of benzaldehyde the humin nitrogen rises rapidly to a maximum of approximately double the amount produced in an ordinary hydrolysis. "The reaction here appears to be wholly chemical. The ammonia nitrogen is not significantly altered, although there is evidence that some deamination takes place." When fibrin is hydrolyzed in the presence of formaldehyde an initial gain of humin when small amounts of formaldehyde are used is observed, but a large loss when greater quantities of the aldehyde are present.

"Both tryptophan and tyrosin yield a very considerable proportion of 'acid-insoluble' humin nitrogen when boiled with hydrochloric acid in the presence of benzaldehyde. When tryptophan is boiled with formaldehyde, in the presence of hydrochloric acid, a very considerable part of the nitrogen is retained in the acid-insoluble humin. This is in decided contrast to the behavior of tyrosin, where no acid-insoluble humin is formed, but where a greater or less percentage of the nitrogen is retained in the 'acid-soluble' humin, the amount retained depending upon the quantity of formaldehyde present. Some deamination occurs in both amino acids, when heated with either aldehyde, in the presence of hydrochloric acid."

It is indicated that "when nitrogenous compounds other than proteins are present in a hydrolyzate no reliance can be placed upon the figures obtained in any of the fractions, as representing actual amino acids. Such data should not be compared with those obtained by the analysis of pure proteins."

**Formation of hematoporphyrin in ox muscle during autolysis, R. HOAGLAND** (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 1, pp. 41-45).—Experimental data obtained in the course of a study of autolysis in ox muscles demonstrate that the striated muscular tissue of the ox contains enzymes which, under anaerobic conditions, readily reduce oxyhemoglobin to hematoporphyrin. The probability that hematoporphyrin may be a regular intermediate product in the transformation of hemoglobin into bile pigments is indicated.

The autolyses studied covered periods ranging from 7 to 220 days.

**Biochemical reaction of rancid fats, J. VINTILESCU and A. POPESCU** (*Bul. Chim. [Bucharest]*, 17 (1915), pp. 145-150; *abs. in Chem. Zentbl.*, 1916, I, No. 5, p. 235).—Fats which have become rancid and have been exposed to the air absorb oxygen, which can be liberated through peroxidase. The oxygen ab-

sorbed is detected by the well-known guaiac reaction, and the degree of rancidity thus determined. The following test is described:

To about 10 gm. of the sample in a test tube (solid samples being slightly heated to melt them) from 4 to 5 drops of a 5 per cent aqueous blood or hemoglobin solution, 10 drops of freshly prepared tincture of guaiac, and about 10 cc. of water are added and the mixture thoroughly shaken for a few minutes. Rancid fats give a blue color reaction with this test, the strength of which increases with the degree of rancidity. A more decided reaction is obtained if, after shaking the mixture, an equal volume of 96 per cent alcohol is added.

The guaiac tincture is made by dissolving 5 gm. of gum guaiac in 100 cc. of 70 per cent hot alcohol. The hemoglobin solution is made by dissolving 3 gm. of the solid in 100 cc. of water, and, after thorough agitation, letting the solution stand exposed to the air in a wide-mouthed flask.

The free fatty acids present in the rancid fat on heating to 120° C. do not influence the reaction, while previous heating to 200° hinders the reaction.

On the localization of acids and sugars in fleshy fruits, E. DEMOUSSY (*Compt. Rend. Acad. Sci. [Paris]*, 161 (1915), No. 15, pp. 443-445).—Analytical data as to the juices of purple plums, under- and overripe greengages, apricots, under- and overripe peaches, under- and overripe grapes, strawberries, melons, cherries, and tomatoes are submitted. The juices were obtained by subjecting the fruits to increasing pressure. The data include the number of grams of acid (as malic) and reducing and nonreducing sugars per 100 cc. of juice.

From the data a considerable variation in the acidity of the various fruits was observed. The variations in the sugar content were, however, relatively less.

It is deemed probable that the cells which offer the least mechanical resistance and are the most permeable do not have the same composition as those which furnish the sugars. The difference in their physical structure, probably a variation in the thickness of their walls, is accompanied by a difference in the chemical composition of their contents. There is localization, but it is not the same for all the fruits. Sometimes the most resistant cells contain the least amount of acid and reducing sugars and are rich in saccharose. Sometimes the reverse is true. The composition of the fruit thus varies in different parts in spite of its apparent homogeneity and uniform distribution of water. The semipermeability of the protoplasm prevents the diffusion of soluble material.

This localization of soluble material explains the peculiar fact observed in certain fruits, especially plums and apricots, of an increased acidity in the cooked fruit. By crushing the fruit cold, as acid a juice is obtained as by cooking. It is thought that this increased acidity can not be attributed to any diastatic action, fermentation, or oxidation, but to a dissociation of those cells in which the acid is localized.

Studies in the chemistry and physiology of the leaves of the betel vine (*Piper betle*) and of the commercial bleaching of betel-vine leaves, II, H. H. MANN and V. G. PATWARDHAN (*Mém. Dept. Agr. India, Chem. Ser.*, 4 (1916), No. 7, pp. 281-322).—Continuing the work previously noted (*E. S. R.*, 31, p. 108), the authors report and discuss analytical data on the moisture, reducing and nonreducing sugars, starch, tannin, ether extract and essential oil, nitrate, and acid content of leaves picked in the morning, at noon, and at night; the varieties of betel-vine leaves, their qualities, and the essential oil in them; and the chemistry of the essential oil of the leaves. The commercial bleaching of the betel-vine leaf is also discussed in some detail.

The use of the centrifuge in analytical chemistry, O. NOLTE (*Landw. Vers. Stat.*, 87 (1915), No. 6, pp. 449-457, pl. 1).—The use of the centrifuge for separating precipitates in the determination of sodium, potassium, calcium, and phosphorus is discussed and the procedures used are described. The ease of manipulation and the economy of time are indicated as making its use of practical importance.

Note on the applicability of the paper pulp filter to the separation of solids from liquids, S. L. JODIT (*Jour. Franklin Inst.*, 182 (1916), No. 1, pp. 61-67; *Chem. Engin. and Manfr.*, 24 (1916), No. 2, pp. 79-81).—This is a short review of the material previously noted (E. S. R., 34, p. 712; 35, pp. 204, 314).

"Plate" forms of ultrafiltration apparatus, G. S. WALPOLE (*Biochem. Jour.*, 10 (1916), No. 2, pp. 254-262, figs. 3).—The construction and use of two patterns of an ultrafiltration apparatus, using the collodion film as previously noted (E. S. R., 35, p. 612), is described in detail.

A note on the sulphone-phthaleins as indicators for the colorimetric determination of hydrogen-ion concentration, H. A. LUBS and W. M. CLARK (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 14, pp. 481-483).—This article outlines certain modifications in the methods of preparation of a number of sulphone-phthaleins which were previously described by the authors.<sup>1</sup> The color changes and the approximate ranges of the various sulphone-phthaleins are given in tabular form.

The colorimetric determination of the hydrogen-ion concentration of bacteriological culture media, W. M. CLARK and H. A. LUBS (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 14, pp. 483-489).—This is a short review of the results of the work previously reported by the authors (E. S. R., 34, pp. 136, 804; 35, p. 801).

The determination of potassium in potassium salts by the perchlorate method, G. HAGER and J. KERN (*Landw. Vers. Stat.*, 87 (1915), No. 4-5, pp. 365-380).—From an investigation of the method, using pure potassium salts, the authors found that the solubility of the potassium perchlorate in alcohol-containing perchloric acid increases with decreasing strength of the acid in the alcohol. With an increased amount of perchloric acid the solubility markedly decreases. The presence of contaminating salts has the same influence on the solubility. The smaller the amount of contaminating salts the more necessary does the use of alcohol of not less than 96 per cent by volume strength become. Potassium salts which contain considerable amounts of sulphate always yield low results, as the precipitated barium sulphate carries down potassium salts. This error is not only inherent in the perchlorate method but in any procedure in which the sulphates are precipitated by barium chlorid.

The estimation of potassium in presence of other substances, A. H. BENNETT (*Analyst*, 41 (1916), No. 483, pp. 165-168).—The author describes a procedure in which the potassium is first precipitated as potassium cobaltinitrite, the precipitate dissolved in a small amount of hot dilute hydrochloric acid, filtered into an evaporating dish and evaporated to dryness, the residue dissolved in hot water, and the potassium then precipitated as perchlorate with perchloric acid.

The method is deemed applicable for the estimation of potassium in wine lees, argols, and tartars, and in liquors of tartaric acid works, where it occurs in the presence of free tartaric acid, sulphuric acid, phosphoric acid, iron, aluminum, and organic matter. When the solution contains rather large amounts of iron and aluminum phosphates they will be precipitated with the

<sup>1</sup> *Jour. Wash. Acad. Sci.*, 5 (1915), No. 18, pp. 609-617.

cobaltinitrite and so interfere with the results. This can be avoided, however, by the addition of sodium citrate, which will keep the phosphates in solution during the cobaltinitrite precipitation.

The estimation of calcium, E. CAHEN and W. H. HURTLEY (*Biochem. Jour.*, 10 (1916), No. 2, pp. 308-312).—The residue after the destruction of the organic matter in certain biological materials was found to be completely soluble in sulphuric acid only after prolonged heating. By using phosphoric acid the authors succeeded in effecting complete solution after only a few minutes of heating. The method is described as follows:

The organ or tissue is dried at 100° C. and incinerated in the usual way. Liquid samples are first evaporated on the water bath, dried at 120°, and then incinerated as usual. To the residue 20 cc. of phosphoric acid of specific gravity 1.2 (one volume sirupy phosphoric acid to three volumes water) are added if much calcium is present; if only a little is present 10 cc. or even less is used. On warming the calcium dissolves completely. This liquid is diluted with 50 or 100 cc. of water, according to the amount of calcium present, and the calcium then precipitated by a solution of oxalic acid of proper strength, about five times the theoretical amount of acid being added. Precipitation is rapid and the precipitate is crystalline, but a little calcium remains in solution. To effect complete precipitation ammonia equal in strength and volume to the oxalic acid used is added. If magnesium is present the ammonia must be added slowly and with shaking. The precipitated solution is allowed to stand for one hour, after which it filters quickly and perfectly clear. The calcium is then determined either by a slightly modified volumetric procedure, or by the usual gravimetric procedure.

Comparative experimental data indicate the accuracy of the procedure.

A new color reaction for "oxycholesterol," MARY C. ROSENHEIM (*Biochem. Jour.*, 10 (1916), No. 2, pp. 176-182, pl. 1).—A color reaction of cholesterol with technical dimethyl sulphate is described, the spectrum of which shows two absorption bands. The reaction is not given by pure dimethyl sulphate and is deemed due to the presence of monomethyl sulphate in the technical product. "Oxycholesterol" was found to give a purple color reaction with technical dimethyl sulphate which showed an absorption band in the yellow. A typical green reaction was obtained with oxycholesterol and pure or technical dimethyl sulphate after the addition of ferric chlorid showing a well-defined absorption band in the red.

Note on the detection of crude beet sugar in cane products, H. PELLET (*Bul. Assoc. Chim. Sucri. et Distill.*, 33 (1916), No. 7-9, pp. 169-171).—The presence of even small amounts of crude beet sugar in cane products is undesirable on account of the disagreeable taste and odor it imparts to the product. The taste, however, is not always a satisfactory indication of the presence of the beet products. Analytical data of the nitrogenous content of crude cane and beet sugars show a decidedly greater quantity in the beet product. It is indicated that the observations reported may serve as a means of detecting the presence of the crude beet sugar in the cane products.

A simple and rapid method for the estimation of volatile acid in wine, W. V. CRUESS and R. W. BETTOLI (*Off. Rpt. Sess. Internat. Cong. Vit.*, 1915, pp. 263-267).—A simple method for the determination of volatile acids in wine, suitable for the ordinary wine maker, is described. It consists essentially of estimating the total acid in the untreated wine, then in the wine after driving off the acetic acid, and thus calculating the volatile acid by difference.

The improved procedure, briefly described, consists of decolorizing about a 75-cc. sample with bone black free from carbonates. The completely decolorized wine is then filtered and a 20-cc. sample titrated with tenth-normal alkali

(a), using phenolphthalein as an indicator. Another 20-cc. portion of the decolorized wine is then mixed with approximately 2 gm. of sodium chlorid in a 200-cc. Erlenmeyer flask, and the liquid is rapidly evaporated until a copious separation of sodium chlorid takes place and the wine begins to spatter. Twenty cc. of distilled water is now added and the evaporation repeated until sodium chlorid again separates. The liquid is diluted with distilled water and then titrated with tenth-normal alkali (b), using phenolphthalein as indicator. The amount of volatile acid in grams per 100 cc. is calculated from the formula  $(a-b) \times 0.03$ . The use of the factor 0.03 is described in detail. Comparative analytical data submitted indicate the accuracy of the method.

The effect of the number of evaporations and of the sodium chlorid concentration is also discussed.

The composition of some lime-sulphur sprays made according to recognized formulas, A. A. RAMSAY (*Jour. and Proc. Roy. Soc. N. S. Wales*, 48 (1914), pt. 2, pp. 242-252).—This article reports analytical data of a number of lime-sulphur solutions prepared according to various formulas. From these data certain deductions as to the proper method of preparation of the solutions for use under various conditions are indicated.

Canning and preserving with 4-H recipes, JANE S. MCKIMMON (*N. C. Agr. Ext. Serv. Circ. 11* (1916), pp. 3-38, figs. 9).—This circular contains the regulations and standards to which members of the North Carolina canning clubs are expected to conform. Some things to be observed when canning, instructions to agents, and canning directions, etc., are included.

How can vegetables be best conserved? THEKLA FRIEDLAENDER AND ELISABETH DAMMER (*Zent. Einkaufsgesell. Beschränkt. Haftung, Flugschr. No. 4* [1915], *Orig.*, pp. 24, fig. 1).—This pamphlet discusses methods for conserving vegetables by natural drying, forced drying, salting, pickling, and various processes of canning. Recipes and detailed procedures for the various processes are described.

The laboratory kitchen recipes for putting up fruits, with directions, THEODORA M. CARRELL (*Poughkeepsie, N. Y.: Author, 1916*, pp. 27).—This pamphlet briefly describes the utensils necessary for putting up fruit and discusses the usual methods of canning and subsequent sterilization. Recipes and directions, which have been tested in the laboratory kitchen at Vassar College, for preparing jellies, jams, preserves and conserves, fruit juices, pickles, marmalades of citrus fruits, preserved fresh fruits, mincemeat, and tutti frutti are given.

The canning of fruits without sugar, HEDWIG HEYL (*Zent. Einkaufsgesell, Beschränkt. Haftung, Flugschr. No. 24* (1916), *Orig.*, pp. 16).—This pamphlet outlines procedures for the canning of fruits without sugar. Recipes for preparing marmalades, fruit juices, pickled fruits, relishes, and products canned in vinegar are included. A note on the drying of fruits is also given.

Some results of the practical application of sulphurous acid and selected yeast in the fermentation of California Wines, 1913 and 1914, W. V. CRUESS (*Off. Rpt. Sess. Internat. Cong. Vit., 1915*, pp. 254-263).—Extended analytical data are submitted from which the following conclusions are drawn:

"The quality and soundness of wines made in the ordinary commercial cellars can be raised very materially by the use of sulphur dioxide and pure yeast. Special technical knowledge is not necessary for their use and they can be applied by the average wine maker."

Influence of composition on effervescence of champagne. Preliminary investigations, R. W. BETTOLI and J. LA BELE (*Off. Rpt. Sess. Internat. Cong. Vit., 1915*, pp. 267-275, figs. 7).—The authors have studied the influence of sugar, tartaric acid, citric acid, tannin, glycerin, and extract (solids) on the

"sparkle" of champagne. For determining the rate of the liberation of gas a Lunge gas volumeter was used. Chemical analysis of the wines examined included the determination of alcohol, acidity (free as tartaric, volatile as acetic, and fixed as tartaric), reducing sugars, solids, sugar-free solids, and tannin. The analytical results obtained are expressed in graphical and tabular form.

While the experiments described are of a preliminary nature and no definite conclusions are drawn, it is indicated that "sugar, tannin, and glycerin exert a marked retardative action on the effervescence, while with the tartaric and citric acids the effervescence seems to be prolonged and not hastened. The fixed acidity of the wines used in the experiments was already exceptionally high so that any effect due to acidity may not have been so noticeable as it would have otherwise been."

**The coloring matter of cane juices.**—A preliminary report, M. A. SCHNELLER (*Louisiana Stas. Bul. 157 (1916), pp. 16*).—The material from which the conclusions previously noted (*E. S. R., 35, p. 312*) have been drawn is discussed in detail.

In addition it is concluded that "the polyphenol content of juices could be reduced by topping cane low, using tops for planting. This would result in a distinct improvement of the color of juices."

**Secrets of meat curing and sausage making** (*Chicago: B. Heller & Co., 1916, 3. ed., pp. 247, figs. 48*).—This booklet describes the slaughtering and dressing of hogs for the market; the curing of hams, shoulders, and bacon; the rendering of lard; and the slaughtering of animals on the farm; and outlines many recipes for the preparation of sausages, etc.

## SOILS—FERTILIZERS.

**Principles of plant nutrition and manuring**, W. KLEBERGER (*Grundzüge der Pflanzenernährungslehre und Düngerlehre. Hannover: M. and H. Schaper, 1914, pt. 1, pp. XII+35½; 1915, pt. 2, pp. IX+291, pls. 11*).—The first part of this work deals mainly with soils as regards their constitution, structure, and conditions, also modifications thereof. The second part deals with soils as a factor in plant nutrition and as modified by plant life, the concluding chapter dealing with the classification and relative values of soils.

Each of the two parts contains a bibliography.

**The making of the soil**, E. J. RUSSELL (*Trans. Highland and Agr. Soc. Scot., 5. ser., 28 (1916), pp. 1-32, figs. 13*).—This article deals with the natural processes and artificial processes such as tillage, drainage, and fertilization involved in the formation of arable soil.

**Agricultural soils and their composition**, J. PUIG Y NATTINO (*Rev. Min. Indus. Uruguay, 4 (1916), No. 20, pp. 58-111, pls. 5, figs. 3*).—This article discusses and compares French, Italian, and German methods of mechanical analyses of soil and reports the results of physical analyses of 74 samples of Uruguay soils.

**Soil survey of Franklin County, Florida**, C. N. MOONEY and A. L. PATRICK (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 31, fig. 1, map 1*).—This survey issued September 30, 1916, deals with the soils of an area of 346,240 acres in the Gulf coast region of central western Florida, the surface of which "is a flat, featureless plain, and only along the coastal borders and up the main streams is there any topographic relief. These borders apparently are higher and are well drained, while the interior of the county is flatwoods country comprising a large number of almost impenetrable bays or swamps. . . ."

"The soils of the county are of marine sedimentary origin and are predominantly sandy. There are two general groups, the light-colored, well-drained soils and the poorly drained, or dark-colored, soils."

Including shell mounds, muck, coastal beach, tidal marsh, and swamp, 13 soil types of 6 series are mapped, of which the Hyde fine sand, the Plummer fine sand, and swamp cover, respectively, 34.3, 22.6, and 10.9 per cent of the area.

Soil survey of Jewell County, Kansas, L. E. CALL, R. I. THROCKMORTON, C. O. SWANSON, ET AL. (*Kansas Sta. Bul. 211 (1916), pp. 36, map 1*).—This report of a survey made in cooperation with the Bureau of Soils of the U. S. Department of Agriculture deals with the general characteristics and chemical composition of the soils of an area of 578,840 acres in northern Kansas.

"The soils of Jewell County fall naturally into four general groups: (1) Residual soils, or those derived from the underlying rocks; (2) loessial soils, or those formed from the weathering of wind-blown deposits; (3) soils of mixed loessial and residual origin; and (4) alluvial soils, or those laid down by streams." Nineteen soil types of 7 series are mapped, of which the Colby silt loam and silty clay loam cover 52.3 and 16.9 per cent, respectively. Average chemical analyses of the different soil types are also reported, which are taken to indicate that the potassium, phosphorus, and lime contents are relatively high, although the phosphorus is more available in the soil than in the subsoil. It is pointed out that the cultivated soils have lost from one-fourth to two-fifths of the nitrogen originally present in the virgin soil.

Some soils from the Kuala Pilah and Jelebu districts, J. GRANTHAM (*Agr. Bul. Fed. Malay States, 4 (1916), No. 8, pp. 243-247*).—Mechanical and chemical analyses of five samples of padi soils, three samples of rubber soils, two samples of jungle soils, and one sample of white soil are reported and discussed.

Critical contribution on the origin of the Mediterranean red soils, E. BLANCK (*Landw. Vers. Stat. 87 (1915), No. 4-5, pp. 251-314*).—This is a critical review and analysis of work bearing on the subject conducted by the author and others.

The results are taken to indicate that generally, where the presence of dolomite has caused the absence of humus, conditions are favorable to the formation of red soil, depending on the action of climatic factors which partially or wholly prevent humus accumulation. The part played in the formation of red soil by insoluble residues of limestone origin is considered of minor importance, since such residue forms only a small part of the red soil and can not account for iron accumulations. The latter are attributed to the metasomatic displacement of lime and to the powers of diffusion of iron solutions added from without.

Humification of compounds contained in vegetable organic matter, A. TRUSOV (TRUSSOFF) (*Selsk. Khoz. i L'vov., 250 (1916), Mar., pp. 339-361*).—Experiments, especially with dry maple leaves, to determine the amount of humus formed during the decomposition of vegetable residues in surface soil are reported.

It was found that the content of water-soluble humus in decomposing organic matter varied, amounting to 1.93 per cent in maple leaves gathered soon after their fall. The plant residues contributed more actively to humus formation and the content of humus soluble in ammonia was larger during the earlier stages of decomposition. The relations between the amounts of humus soluble in water and in ammonia varied with different vegetable materials and periods of decomposition. Frequent drying of the leaves during decomposition decreased the humus content. During decomposition there was no increase in humus content after eight days, and after 156 days no water-soluble humus was found.

Measuring biological actions by the freezing-point method directly in the soil, G. J. BOUYOUKOS (*Science, n. ser., 44 (1916), No. 1124, pp. 65, 66*).—Experiments conducted at the Michigan Experiment Station on the influence of the decomposition of dried blood, cottonseed meal, and animal tankage in soils on the concentration of the soil solution as indicated by depression in the freezing point are reported. The fertilizers were added at the rates of 0.5 and 1 gm. per 800 gm. of soil.

It was found that "the decomposition of these nitrogenous materials increased the depression, and hence the concentration, of the soil solution markedly, and the magnitude of the increase seems to vary with the nature of the material and quantity employed. In some other experiments the amounts of these nitrogenous materials were used, not in equivalent weight but in equivalent nitrogen content, and the freezing-point depression was measured at various intervals. The results show that dried blood reached its maximum decomposition first, followed by animal tankage and cottonseed meal, respectively. . . .

"It appears that the freezing-point method may be used to great advantage in making comparative studies of the decomposibility of various organic substances in the same kind of soil, or the decomposing power of different classes of soil on the same organic substance, or of the same soil differently treated, etc."

Effect of grinding soil on the number of micro-organisms, E. B. FRED (*Science, n. ser., 44 (1916), No. 1130, pp. 282, 283*).—Tests with silt loam, clay, sand, silt clay loam, sandy loam, medium sand, loam, muck, and garden soils to determine the influence of grinding on the number of micro-organisms showed that "grinding greatly reduced the number of bacteria except in silt loam. Apparently the greatest injury caused by grinding for one hour is noted in the case of sandy soils. When the soils were ground for 8 or 24 hours, there was an enormous decrease in the bacterial flora. . . . After 24 hours of grinding the soil was rendered almost free of bacteria. . . .

"Dilution counts on various culture solutions adapted to protozoa showed that the unground soils contained protozoa in dilutions greater than 1 to 10,000, while in many cases the ground soil failed to show any growth of protozoa. The garden soil contained protozoa in the first dilution, 1 gm. in 10 cc. of the medium. When ground for 24 hours this same soil did not show the presence of protozoa.

"From the results, it seems fair to conclude that grinding soil in a ball mill injures the soil micro-organisms. If this process is continued for several hours, the soil will be partially sterilized."

The gases of swamp rice soils.—III, A hydrogen-oxidizing bacterium from these soils, W. H. HARRISON and P. A. SUBRAMANIA Aiyer (*Mem. Dept. Agr. India, Chem. Ser., 4 (1916), No. 4, pp. 135-148, fig. 1*).—Continuing work previously noted (*E. S. R., 33, p. 216*), further studies were made on the bacteria in the film on the surface of swamp-rice soils, which had previously shown the ability to oxidize hydrogen.

Cultivation of a crude culture in Kaserer's medium (*E. S. R., 18, p. 1028*) under autotrophic conditions and incubation in an atmosphere consisting of a mixture of carbon dioxide, methane, oxygen, and hydrogen yielded a culture composed of a mixture of two species of bacteria, one nonmotile and the other smaller. Further cultivation of the mixed culture in the medium to which organic matter was added led to the conclusion that the particular bacterium which was able to oxidize hydrogen was unable to exist in pure culture under autotrophic conditions. "The mixed culture was plated out on mineral agar, to which 0.1 per cent sodium asparaginate had been added, and incubated in

an atmosphere of oxygen and hydrogen. Colonies developed of which a large number proved to possess the power of oxidizing hydrogen in the presence of soluble nitrogenous organic matter and which were found to consist of the larger nonmotile bacterium previously referred to."

The characteristics of the bacterium are described in detail, together with the experimental details of the work.

**Relations between water and soil.** H. FISCHER (*Internat. Mitt. Bodenk.*, 5 (1915), No. 5-6, pp. 517-576, fig. 1; *abs. in Chem. Abs.*, 10 (1916), No. 10, p. 1391).—Analyses of a number of soils, especially swamp soils, and soil waters which had undergone different natural changes and fertility treatments are reported and discussed with special reference to the judgment of the value of the soils. It is concluded that in judging the productiveness of a soil it is necessary, not only to analyze the soil and soil water and to conduct plat and pot tests and fertilizer experiments, but also to classify the soil with reference to regional and climatic conditions and thereby compare the results of natural and artificial changes.

**Comparative tests of methods for determining cohesion, with special reference to marsh soils.** C. MARQUIS (*Internat. Mitt. Bodenk.*, 5 (1915), No. 5-6, pp. 381-516, figs. 14; *abs. in Chem. Abs.*, 10 (1916), No. 10, p. 1391).—A comparison of methods of measuring cohesion in soils with different moisture and lime contents, including experiments on the draft of plows under varying soil conditions, is reported. It was found that moisture content was the most important factor determining the variation in cohesion values, and minimum cohesion was observed in each soil at a moisture content corresponding to its character.

**Acidity and adsorption in soils as measured by the hydrogen electrode.** L. T. SHARP and D. R. HOAGLAND (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 3, pp. 123-145, fig. 1).—Experiments conducted at the California Experiment Station with silty clay loam, fine sandy loam, sandy loam, gravelly loam, clay adobe, silty loam, and peat soils on the relation between soil reaction and the concentration of the hydrogen ion in soil suspensions and extracts are reported, together with the progress results of experiments on the influence of varying proportions of soil to water, grinding the soil, heating it at various temperatures, and of the addition of salts on the H-ion concentration. "Consideration has also been given to the relation of  $\text{HCO}_3^-$ ,  $\text{CO}_3^{2-}$ , and  $\text{CO}_2$  to soil reaction as measured by the electrometric method. Experimental data have likewise been secured with respect to the lime requirement of soils and the so-called 'adsorption of bases.'" A hydrogen electrode apparatus for determining small differences in potential was used to measure hydrogen-ion concentrations in soil suspensions.

Hydrogen electrode measurements gave direct evidence that soil acidity is due to the presence of an excess of hydrogen ions in the soil solution. "The hydrogen-ion concentration of different soil suspensions was found to vary within wide limits, from a condition of high acidity to one of high alkalinity. Soils containing calcium in equilibrium with  $\text{HCO}_3^-$  and  $\text{CO}_2$  have a very slightly alkaline reaction."

With one exception, grinding did not materially alter the hydrogen-ion concentration of the soil suspensions. Varying the proportion of soil to water produced only slight fluctuations in hydrogen-ion concentration in soil suspensions.

"The intensity of acidity decreases when the soils are heated at high temperatures. The insufficiency of the data concerning heating at  $140^\circ\text{C}$ . does not admit of positive conclusions, though there is indication that the H-ion concentration may be slightly increased by this treatment. . . .

"The addition of sodium chlorid, potassium chlorid, and barium chlorid to certain soil suspensions was found to increase the hydrogen-ion concentration." There was found to be apparently a simultaneous removal of positive and negative ions from solutions of various hydrates by soils.

A list of 35 references to literature bearing on the subject is appended.

**Soil alkali studies: Quantities of alkali salts which prohibit the growth of crops in certain Utah soils,** F. S. HARRIS (*Utah Sta. Bul. 145 (1916), pp. 21, figs. 16*).—In an extension to field conditions of studies previously reported (*E. S. R., 34, p. 125*), determinations of the total soluble salts, including chlorids, carbonates, and sulphates, to a depth of 4 ft. in soils from seven counties in Utah were made. The crops growing on the soils were wheat in five cases and oats and alfalfa one each. "Samples were taken from typical alkali spots, from parts of the same field producing good crops, and from places surrounding the bare spots where only about a half crop was produced." The results are reported graphically.

It was found that the highest concentration and the location of salts varied considerably, occurring in some soils in the surface foot and in others at depths of 2, 3, and 4 ft. The total soluble salts in the parts of the fields producing the best crops varied from 2,440 parts per million in Salt Lake County to 10,852 parts per million in Millard County, with an average of 5,089 for all seven counties. The parts of the field where the yield had been reduced to about half what it was in the better places varied in total soluble salts from 2,956 parts per million in Carbon County to 18,325 parts per million in Millard County, with an average of 9,263 parts per million for all the counties. The total salts varied in the bare places from 6,938 parts per million in Salt Lake County to 30,148 parts per million in Cache County, with an average of 14,397 parts per million. There was considerable variation in the chlorids and carbonates, but very much more in the sulphates, the latter running as low as 543 parts per million in Boxelder County and as high as 23,027 in Cache County.

The toxic limits for total salts were considerably lower in the eastern counties. "No crops grew where there were 14,397 parts per million of salts. . . . As an average of the three counties where sulphates were low, no crops were produced with a concentration of 10,709 parts per million of salts, while there was only half a crop with 6,455 parts per million."

[**Studies on soils**] (*California Sta. Rpt. 1916, pp. 59, 60*).—In studies by W. P. Kelley on the effect of sodium nitrate on soils, it was found that the continued use of this material resulted (1) in a well-defined deterioration in the physical properties of the soils, (2) in a rapid loss of soil calcium, and (3) in an unusually high content of soluble sodium in proportion to other bases in the water extracts from such soils. It was concluded that sodium nitrate reacts with calcium carbonate in soils to form small amounts of sodium carbonate.

Studies of nitrification in California soils are said to show the favorable influence of manure and leguminous cover crops and only a slight effect of inorganic fertilizers on nitrification. Leguminous cover crops are said to undergo much more rapid nitrification than barley or manure. The results of a comparative study of the nitrification of leguminous cover crops are taken to indicate that *Medilotus indica*, purple vetch, common vetch, and bur clover each contain about the same amounts of nitrogen and likewise undergo rapid nitrification. Canada field peas and Windsor beans, on the other hand, were somewhat inferior in this respect.

The results of studies on the movement of nitrates in soils are taken to indicate that nitrates are naturally formed in cultivated zones to the greatest extent and that where cover crops and manure are plowed down the porosity of

the soil permits more uniform diffusion and movement of nitrates into the substrata.

**Comparison of the nitrifying powers of some humid and some arid soils,** C. B. LIPMAN, P. S. BURGESS, and M. A. KLEIN (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 2, pp. 47-82).—Studies conducted at the California Experiment Station on the nitrifying powers under incubator conditions of about 40 humid and 150 arid soils, of which at least one sample was obtained from each State in the Union, are reported. "The soil was used as a medium, and the forms of nitrogen employed were soil nitrogen, sulphate of ammonia plus soil nitrogen, dried blood plus soil nitrogen, and cottonseed meal plus soil nitrogen."

It was found that the nitrifying powers of soils of the arid region are no more intense than those of the humid region. It is considered possible that "the data [for soil nitrogen and dried-blood nitrogen] justify the further conclusion that the nitrifying powers of humid soils are greater than those of arid soils. . . . Arid soils nitrify the nitrogen of sulphate of ammonia and cottonseed meal with much greater vigor than do the humid soils. A reversal of efficiency is manifest between the two groups of soils as regards sulphate of ammonia and cottonseed meal on the one hand and dried blood and soil nitrogen on the other."

**The washing out of nitrate from arable soil during the past winter,** E. J. RUSSELL and A. APPLEYARD (*Jour. Bd. Agr. [London]*, 23 (1916), No. 1, pp. 22-27, figs. 2).—Studies of the soils of several experimental fields after an unusually wet winter showed that the high winter rainfall caused a deflocculation of clay and a depletion of the stock of soil nitrates.

**Experiments on the improvement of peat soils by adding mineral soils and lime,** H. VON FEELITZEN (*Svenska Mosskulturför. Tidskr.*, 29 (1915), No. 6, pp. 462-466).—In experiments at Flahult it was found that the addition of a mixture of sand and loam to swamp soil increased the yield of hay. When sand alone was used better results were obtained with oats, timothy, and pasture grass when the sand was spread on the surface than when it was plowed into the soil. Turnips and flax responded best to liming on these soils and red clover and barley least.

**Manuring for higher crop production,** E. J. RUSSELL (*Cambridge, Eng.: Univ. Press*, 1916, pp. [VI]+69, pls. 2, figs. 14).—This is a popular book for English farmers on manures and soil management, which is intended especially to meet emergency conditions due to the European war. It is divided into five chapters.

Chapter 1, the improvement of the soil, deals with cultivation, liming, green manuring, and catch cropping. Chapter 2, the manure heap, deals with the storage, conservation, use, and time of application of manure and liquid manure. Chapter 3, artificial manures, deals with the composition and use of the well-known nitrogenous, phosphatic, and potassic fertilizers. Chapters 4 and 5 deal in turn with the practical manuring of arable land with reference to different common crops and the manuring of grass land.

**Fertilizers,** E. B. VOORHEES (*New York: The Macmillan Co.*, 1916, rev. ed., pp. XV+365, pls. 16, figs. 6).—This is a revised edition of this book by J. H. Voorhees (E. S. R., 10, p. 942). The revision consists of the rearrangement of certain parts, the incorporation of considerable new matter, and the bringing up to date of old matter. A chapter on manures is included; the subject of lime is more fully treated; and more attention is given to the utilization of various by-products and waste products as fertilizers as well as to recently discovered phosphates and phosphate preparation, air nitrogen compounds, and

American sources of potash. Much new matter regarding the fertilizing of truck and market garden crops and other special crops has been added.

Soil fertility, its economic maintenance and increase, F. T. SHUTT (*Canada Expt. Farms Bul. 27, 2. ser., (1916), pp. 13*).—This is an address to farmers' institute workers in which the fundamental principles in the economic maintenance and increase of soil fertility are enumerated and discussed. Special attention is drawn to the importance of the conservation and use of farm manure and of fertilizers as a supplement to manure. Analyses of various kinds of manure are given as follows:

*Approximate average composition of manure (fresh) from various animals.*

Kind of animal.	Relative proportions of solid excrement, liquid excrement, and bedding in manure.	Pounds per ton.	Nitrogen.	Phosphoric acid.	Potash.
			<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Horse.....	Solid excrement.....	1,200	0.55	0.30	0.40
	Liquid excrement (urine).....	300	1.35	Trace.	1.25
	Bedding material.....	500	.50	.15	.60
	Total mixture.....	2,000	.60	.22	.58
Cow.....	Solid excrement.....	1,260	.40	.20	.10
	Liquid excrement (urine).....	540	1.00	Trace.	1.35
	Bedding material.....	200	.50	.15	.60
	Total mixture.....	2,000	.57	.14	.49
Pig.....	Solid excrement.....	990	.55	.50	.40
	Liquid excrement (urine).....	660	.40	.10	.45
	Bedding material.....	350	.50	.15	.60
	Total mixture.....	2,000	.49	.30	.45
Sheep.....	Solid excrement.....	1,206	.75	.50	.45
	Liquid excrement (urine).....	594	.35	.05	2.10
	Bedding material.....	200	.50	.15	.60
	Total mixture.....	2,000	.90	.33	.95
Poultry.....	Solid and liquid excrement.....	1,900	1.00	.80	.40
	Bedding material.....	100	.50	.15	.60
	Total mixture.....	2,000	.97	.77	.41

Analyses of seaweeds collected on the Atlantic seaboard are also reported as in the following table:

*Analyses of seaweeds collected on the Atlantic seaboard.*

	Water.	Organic matter.	Ash.	Nitrogen.	Phosphoric acid.	Potash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
<i>Fucus furcatus</i> .....	63.49	27.93	8.53	0.468	0.108	2.025
<i>F. vesiculosus</i> .....	88.29	7.61	4.10	.182	.037	.615
<i>Ascophyllum nodosum</i> .....	75.14	19.30	5.56	.273	.070	.619
<i>Porphyra laciniata</i> .....	79.42	15.15	5.43	.928	.068	.619
<i>Laminaria longicuris</i> .....	88.30	7.15	4.55	.251	.134	1.546

Manurial values of concentrated foods in relation to cost of food in the production of milk, J. MACKINTOSH (*Jour. Bd. Agr. [London], 23 (1916), No. 3, pp. 209-224*).—Studies of the values of the manurial residues, conducted as a part of an investigation lasting two years into the cost of feed in the production of milk on 39 farms, are reported.

The total weight of feed used during the two years was 1,795 tons, and included decorticated cotton cake and meal, Egyptian cotton cake, compound

dairy cake and meal, linseed cake, dried grains, soy-bean cake and meal, and oats. The first year the net manurial value for all the farms equaled 0.33d. (0.66 ct.) per gallon of milk produced. In the second year the net manurial value was 0.36d. (0.72 ct.) per gallon of milk produced. The range of net manurial values per gallon of milk was from zero to 0.83d (1.66 cts.).

"A comparison of the results from the groups of farms shows that the methods of management of the liquid and solid manure is one cause of variation in the results from the individual farms, but at least two other factors must be taken into account. These are (1) the quantity of cakes and meals used, and (2) the variation in manurial value of individual cakes and meals."

A plan for testing efficiencies of fertilizers, P. L. GILE and J. O. CARRERO (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 4, pp. 247-255, fig. 1).—In a further contribution to the subject (E. S. R., 31, p. 28), "it is proposed that tests of the efficiencies of different fertilizers furnishing the same element shall include applications of three to five different quantities of the standard fertilizer, and that from the data of the tests so planned the efficiencies be calculated on the basis of the relative quantities of the different fertilizers required to produce the same increased yields. It is pointed out that the usual method of conducting such tests and the usual method of calculating efficiencies may be subject to some error, as they are based on an assumption concerning the law of minimum, namely, that the curve of increased growth with increasing amounts of the fertilizer in minimum will be a straight line. This assumption is sometimes false, as the curve may take a variety of forms. . . .

"[The proposed method] being based on no assumption concerning the law of minimum, an accurate comparison is possible irrespective of how the yield increases with increasing amounts of the fertilizer in minimum. The form of the curve, plotted from the increased yields produced by increasing amounts of the standard fertilizer, shows when a calculation of relative efficiencies is allowable, and gives some idea of the accuracy of the comparison. As the proposed method involves the idea of always comparing yields of approximately equal magnitudes, an analysis of the crop and determination of dry matter are not so important as in the old method. This principle of the proposed method is of particular value for vegetative tests in pots where large and small yields are subject to somewhat different conditions in respect to ratio between soil and root volume and total amount of mineral matter supplied in the water."

[Fertilizer experiments], E. F. GASKILL (*Massachusetts Sta. Rpt. 1915, pt. 1, pp. 37a-44a*).—The results of the twenty-sixth year of an experiment with clover and grass on the relative value of barnyard manure, sodium nitrate, ammonium sulphate, and dried blood as sources of nitrogen are reported, together with a summary of the whole period. "On the basis of 100 for nitrate of soda, the relative standing of the different nitrogen plats and no-nitrogen plats, as measured by total yield during the season, was as follows: Dried blood, 102.46; no nitrogen, 99.61; sulphate of ammonia, 99.48; and manure, 99.1; [and] for the 26 years, nitrate of soda, 100; manure, 76.47; dried blood, 75.83; and sulphate of ammonia, 57.93. Considering the relative standing of the different nitrogen fertilizers on the basis of yields per acre with a mixed crop of clover and grass there is very little difference between the different materials, and the no-nitrogen plats gave yields about as large as those receiving nitrogen."

Experiments with asparagus, blackberries, raspberries, currants, rhubarb, potatoes, mangels, and alfalfa on the relative value of potassium sulphate and chlorid as sources of potash gave, except in the case of asparagus, results in agreement with those of previous years. "Considering the different crops grown during the 23 years of the experiment, the muriate has proved the better

source of potash for the following: Asparagus (11 years), currants (4 years), mangels (2 years), sugar beets (1 year), corn, ensilage (1 year), corn stover (7 years), sweet-corn stover (1 year), squashes (3 years), carrots (2 years), onions (2 years), celery (1 year), oat hay (1 year), and vetch and oats (2 years). The sulphate has proved the better source of potash for the following crops: Asparagus (1 year), blackberries (10 years), raspberries (10 years), strawberries (11 years), rhubarb (12 years), potatoes (12 years), corn, grain (7 years), sweet corn, ears (1 year), cabbages (10 years), soy beans (4 years), alfalfa (4 years), crimson clover (1 year), common red and alsike clover (1 year), and mammoth red clover (1 year)."

The results in the twenty-sixth year of a comparative test of two fertilizer mixtures, one high in potash and low in phosphoric acid and the other high in phosphoric acid and low in potash, showed that for the mixture rich in phosphoric acid the yield of crib-dried corn was 46 bu. and the yield of stover 5,420 lbs. per acre, and for the mixture rich in potash, 35.1 bu. of corn and 5,060 lbs. of stover per acre.

The results of the eighth year of a comparison of ammonium sulphate and sodium nitrate as a top-dressing for permanent mowings were "in favor of the nitrate of soda for the first crop, with very little difference between the two for the second crop, and the no-nitrogen plat producing more rowen than either the nitrate of soda or sulphate of ammonia plats. . . . These results . . . indicate in a striking way that beneficial results are obtained by top-dressing with sulphate of ammonia and nitrate of soda, and that the results are immediate but not lasting."

The results of an experiment to study the relative value of different sources of lime on the basis of equal applications of combined calcium and magnesium oxids are briefly noted, medium green soy beans being grown for seed. The following comparative yields per acre are reported: With hydrated lime, 31.2 bu. of seed and 2,484 lbs. of straw; with marl, 30 bu. of seed and 2,435 lbs. of straw; with ground limestone, 30.02 bu. of seed and 2,359 lbs. of straw; with no lime, 28.86 bu. of seed and 2,273 lbs. of straw; and with limoid, 35.25 bu. of seed and 3,209 lbs. of straw.

Other general data are also included on the effect of the continued use of fertilizers containing single plant food elements and of different combinations of plant food elements on different crops, and the relative value of different fertilizer rotations for top-dressings of grass land.

**Sources of nitrogen compounds in the United States**, C. G. GILBERT (*Smithson. Inst. Pub.* 2421 (1916), pp. 12).—This paper discusses the nitrogen situation in the United States and briefly describes the arc method, the cyanamid and Haber processes, and the by-product ammonia method of obtaining nitrogen compounds. The cyanamid process and the by-product coking operation are thought to offer the greatest possibilities in the United States for meeting the agricultural and other requirements for nitrogen.

**Fixation of air nitrogen and the importance of the resulting fertilizer to agriculture**, L. SEIDLER (*Fühling's Landw. Ztg.*, 64 (1915), No. 21-22, pp. 543-556).—A number of processes for the fixation of air nitrogen are described and discussed.

**The preparation of superphosphate from phosphorites from Saratov and Perme**, N. P. KOBLYKOV (*Trudy Kom. Moskov. Sel'sk. Khoz. Inst. Izsl'ed. Fosforitov.*, Ser. II, 5 (1915), pp. 16-22).—Experiments with the two types of phosphorite are reported which show that the Perme phosphorite yielded a product containing 16.2 per cent water-soluble phosphoric acid and the Saratov phosphorite from 11.7 to 11.8 per cent.

**Citrate solubility as a measure for the effectiveness of different Thomas phosphates**, T. PFEIFFER (*Fühling's Landw. Zig.*, 65 (1916), No. 3-4, pp. 81-92, fig. 1).—The author reviews and analyzes the results of several experiments with a number of different Thomas phosphates, and shows that in the majority of cases a definite relation existed between the citrate solubility of the Thomas phosphates and their effectiveness. In one case this assumed the form of a mathematical expression; that is, the effective value of the different Thomas phosphates represented a logarithmic function of their content of citrate-soluble phosphoric acid.

**Potash in the banana stalk**, R. H. ELLIS (*Jour. Soc. Chem. Indus.*, 35 (1916), No. 8, pp. 456, 457).—Analyses of banana stalks indicated that a ton of banana stalks yielded 188 lbs. of dry matter containing 13.7 per cent potash. It is noted that the dried banana stalks contain about two-thirds as much potash as the dried kelp of the American Pacific coast. Similar results obtained by A. J. Hanley at Leeds University are also noted.

**Note on the presence of potash in banana skins**, R. H. ELLIS (*Jour. Soc. Chem. Indus.*, 35 (1916), No. 9, p. 521).—An examination of banana skins showed a total potash content of 1.05 per cent, the dry matter containing 9.03 per cent of potash. See also the above note.

**A few experiments in the slacking and keeping of lime from east and west Götland**, H. VON FEILTZEN (*Svenska Mosskulturför. Tidskr.*, 30 (1916), No. 2, pp. 170-216, pls. 4, figs. 15).—This is a report of experiments on various methods of slaking lime. It is pointed out that lime must be slaked in small quantities, using known amounts of water. The fineness of slaked lime was found to depend on the manner and degree of slaking, from 70 to 80 per cent of particles of a size less than 0.2 mm. being obtained from well-slaked lime. The finer lime powder was found to contain more hydrate and less carbonate and silicate than the coarser powder.

Instructions on storing burned lime are also included.

**Methods of applying lime**, J. HENDRICK and J. M. SMITH (*Trans. Highland and Agr. Scot.*, 5. ser., 28 (1916), pp. 145-157).—Instructions regarding the application of shell lime, lime compost, ground lime, calcium carbonate, shell sand, and marl are given.

**Official report on agricultural lime licensed, inspected, and analyzed during the year 1915** (*Columbus, Ohio: Bd. Agr.*, 1916, pp. 53, fig. 1).—This bulletin gives general information on the purchasing and use of agricultural lime, and reports the results of actual and guaranteed analyses of 58 samples of agricultural limes collected for inspection in Ohio during 1915. A list of agricultural lime manufacturers and dealers in Ohio and the text of the Ohio agricultural lime law are also given.

**Lime in 1915**, G. F. LOUGHLIN (*U. S. Geol. Survey, Mineral Resources of the United States, Calendar Year 1915, pt. 2, pp. 245-264*).—This report, issued August 19, 1916, deals with the production, use, imports, and exports of lime in the United States during 1915.

"The lime manufactured and sold in the United States in 1915 amounted to 3,589,699 short tons, valued at \$14,336,756. This was an increase of 208,771 tons, or 6 per cent, in quantity, and of \$1,067,818, or about 9 per cent, in value compared with sales in 1914. . . . The five leading States in 1915 were, according to quantity of lime sold, Pennsylvania, Ohio, Virginia, West Virginia, and Wisconsin; according to value, Maine ranked third and Wisconsin sixth. . . .

"The quantity of lime for fertilizer in 1915 decreased about 5 per cent in quantity from the figure of 1914, but was considerably higher than in any other preceding year; the value in 1915, however, was 1 per cent greater than that of 1914, and was the greatest yet attained. The average price per ton increased

18 cts. over that of 1914. . . . Lime for fertilizer was sold in 1915 in 29 of the 43 lime-producing States, and represented about one-sixth of the total quantity and one-seventh of the total value of lime sold. Pennsylvania was the leading State, with sales valued at nearly \$1,000,000. . . . Besides burned lime, there were also sold for fertilizer in 1915 810,399 short tons of pulverized limestone, valued at \$893,530.

**Gypsum in 1915**, R. W. STONE (*U. S. Geol. Survey, Reprint from Mineral Resources of the United States, Calendar Year 1915, pt. 2, pp. 151-159*).—This report deals with the production and use of gypsum in the United States during 1915, and states that "although the output of gypsum mined decreased in 1915, the decrease was only a little more than 1 per cent and the decrease in value of products marketed was only about 4 per cent. . . . The quantity mined exceeded that of all previous years except three, 1912, 1913, and 1914. . . . There was also an unusual increase in the quantity sold as land plaster."

**The action of manganese under acid and neutral soil conditions**, J. J. SKINNER and F. R. REID (*U. S. Dept. Agr. Bul. 441 (1916), pp. 12, figs. 3*).—A six years' field test of manganese sulphate used at the rate of 50 lbs. per acre on an acid silty loam soil is reported.

It was found that the effect of the manganese sulphate each year was not beneficial to wheat, rye, corn, cowpeas, or potatoes. The soil required from 1,780 to about 2,750 lbs. of calcium carbonate per acre to neutralize the first 6 in. It is also deficient in organic matter, of poor physical condition, and has a poor oxidizing power. The processes of oxidation were retarded by manganese in most cases of acid conditions in the soil.

Studies on the same plats kept neutralized with lime for the three years following the experiment with the soil in an acid condition indicated that additions of manganese increased the yields of wheat, rye, timothy, beans, corn, and cowpeas, while no difference was produced in the potato crop. The oxidative power of the neutralized soil was also increased by manganese.

"These results on the behavior of manganese as a so-called catalytic fertilizer when acting under acid or neutral soil conditions show that no profitable return is to be expected in soils of a persistent acid tendency until such soils are limed."

**The American fertilizer handbook** (*Philadelphia: Ware Bros. Co., 1916, 9. ed., pp. [398], figs. 2*).—This handbook contains the usual data and information relating to the fertilizer industry (*E. S. R., 34, p. 29*). Among the more important special articles included are the following: Fertilizers: What They Are—How to Apply Them, by H. G. Bell; The Sulphuric Acid Industry: Conditions in the Trade—New Construction—Brief Review of Recent Literature and Recent Patents—Statistics for the United States, by A. N. Fairlie; Possible Sources of Potash in America, by F. K. Cameron; Potash Salts, 1914, by W. C. Phalen; Preventable Losses in Fertilizer Plants, by S. J. Martenet; Sulphur and Pyrite in 1914, by W. C. Phalen; The Cyanamid Industry—World Status, by E. J. Franke; The Production of Phosphate Rock in 1914, by W. C. Phalen; The Cottonseed Oil Industry; An Interesting and Unusual Year—Conditions Have Necessitated Many Changes in Milling Methods—The Future of the Industry, by T. C. Law; The Products and Composition of Cotton Seed, by T. C. Law; and The Western Animal Ammoniate Market: An Unprecedented Advance of Prices for Blood and Tankage During the Fall of 1915—The Demand for Animal Ammoniates Greater than the Production—Monthly Review from May 1, 1915, to April 30, 1916, by J. H. Schmaltz.

Official report on commercial fertilizers licensed, inspected, and analyzed during the year 1915 (*Columbus, Ohio: Bd. Agr., 1916, pp. 221*).—This bulletin gives general information regarding the manufacture, selection, purchase, and

use of commercial fertilizers in Ohio, and reports the results of actual and guaranteed analyses of 565 samples of fertilizers and fertilizing materials offered for sale in Ohio during 1915.

Analyses of commercial fertilizers, R. N. BRACKETT ET AL. (*South Carolina Sta. Bul. 187 (1916), pp. 68*).—This bulletin contains the results of actual and guaranteed analyses and valuations of 1,593 samples of fertilizers and fertilizing materials collected for inspection in South Carolina during 1915 and 1916 with the usual explanatory notes.

### AGRICULTURAL BOTANY.

Influence of certain carbohydrates on green plants, L. KNUDSON (*New York Cornell Sta. Mem. 9 (1916), pp. 5-75, figs. 11*).—Experiments are described in which a number of plants were cultivated in nutrient media to which various forms of sugar were added, the plants being grown in plugged test tubes, cylinders, or flasks.

Corn (*Zea mays*) was found able to absorb through its roots and to assimilate certain sugars, which resulted in increased growth of the plant. The sugars in the order of their beneficial effect on the plants when grown in the light were glucose and fructose, saccharose, and maltose. In the dark, glucose gave the most beneficial results.

With Canada field peas (*Pisum sativum*), growth was found to respond markedly to the presence of sugars, the order of their beneficial influence being saccharose, glucose, maltose, and lactose. Timothy was found to utilize glucose and saccharose, but not lactose when grown in the light. With this plant grown in the dark, all the sugars seem to be utilized. Experiments with radish confirm earlier investigations, glucose, saccharose, maltose, and lactose being utilized. Vetch (*Vicia villosa*) grown in the dark utilized the various disaccharids. When grown in the light, the order of the favorable influence of the different sugars was saccharose, glucose, maltose, and lactose. Cabbage grown in the presence of maltose showed increased growth, and the same was true for sweet clover with increased concentrations of glucose or saccharose and for crimson clover with maltose.

Vetch plants showed increased growth with increase in concentration of sugars, and these plants were found to absorb glucose from an extremely weak solution. Certain forms of sugars were found toxic in various degrees, and antagonistic actions were observed between different forms of sugars.

In connection with the experiments with vetch, the respiration of the plants was determined. It was found that saccharose and glucose were much alike in their effect, while maltose produced a lessened evolution of carbon dioxide.

An extensive bibliography is given.

Studies on the formation and translocation of carbohydrates in plants (*Jour. Agr. Sci. [England], 7 (1916), No. 3, pp. 255-384, figs. 18; abs. in Gard. Chron., 3. ser., 59 (1916), No. 1526, p. 172*).—This report in three parts, as indicated below, of work done at Rothamsted Experimental Station, had for its object to throw light on the fundamental problems of carbohydrate formation, transfer, storage, transformation, and utilization. Credit for furnishing a complete account of work done as late as 1893 is given to Brown and Morris (E. S. R., 4, p. 984; 5, pp. 127, 344).

I. *The carbohydrates of the mangold leaf*, W. A. Davis, A. J. Daish, and G. C. Sawyer (pp. 255-326).—This section deals with a study of the formation and translocation of the sugars in the mangold under actual conditions of growth. Starch is said to be absent from the leaf after very early stages of growth of the root. During all hours and at all stages, maltose is absent from

leaf, midribs, and stalk. Saccharose exceeds hexoses somewhat in the very young leaves, the reverse being true later in the season. In the midribs and stalk, saccharose remains practically constant throughout the season, being greatly exceeded by the hexoses, which show great diurnal and seasonal variation. During the daytime, the curve of the proportion of saccharose follows the curve of the temperature, while the rise of the curve of hexoses exceeds that of the curve of the temperature.

The facts are thought to support the view that saccharose is the primary sugar formed under the influence of chlorophyll in the leaf mesophyll. Before translocation, it is transformed into hexoses in the veins, midribs, and stalks, the proportion of hexoses increasing as the material approaches the root which it enters as hexose. It is there reconverted into saccharose, in which form it can not leave the root until reconverted for use in the second season's growth. It is considered improbable that the synthesis of hexoses to saccharose is effected by invertase through a process of reversible zymo-hydrolysis, as invertase is entirely absent from the root. Pentoses, which form only a small proportion of the total sugars in the tissues, are thought to be formed from hexoses and to be the precursors of the pentosans.

II. *The dextrose-levulose ratio in the mangold*, W. A. Davis (pp. 327-351).—In this work, it is said to have been found that in the extracts of mangold leaves and stalks optically active impurities are always present which are not precipitated by basic lead acetate and which hence vitiate the estimation of dextrose and levulose. These substances are possibly acid amids or amino-acids which form soluble lead salts, and occur much more abundantly in the midribs and in the stalks than in the leaves. When the ratio of dextrose to levulose is greater than unity (the value to be expected if they are formed into saccharose by inversion), it is thought that the apparent dextrose present is increased by the presence of a dextrorotatory impurity, possibly glutamin. When the ratio is less than unity, as at certain times of day, a levorotatory impurity is thought to predominate. In midribs and stalks, and especially near the bases of the latter, the dextrose appears (probably on account of the impurity above mentioned) to exceed largely the levulose. Apparent fluctuations in the ratio of dextrose to levulose are thought to be due to fluctuations in the optically active impurities rather than in these sugars themselves. These apparent fluctuations show some diurnal regularity. The presence of at least two optically active substances at different hours is thought to be indicated. It is provisionally held that the dextrose and levulose exist in the leaves and stalks as invert sugar, and travel in nearly or exactly equal proportions to the root, where retransformation into saccharose occurs. Which of these sugars is the better adapted to tissue formation or to respiration is not considered as settled by studies thus far reported.

III. *The carbohydrates of the leaf and leaf stalks of the potato. The mechanism of the degradation of starch in the leaf*, W. A. Davis and G. C. Sawyer (pp. 852-884).—It is stated that in potato leaf the increase of saccharose, the principal sugar present when the tubers begin to develop, goes on uniformly from sunrise to 2 p. m., following approximately the temperature curve, but showing a steady decline during the rest of the 24 hours.

Hexoses appear in the leaves in very small amounts, generally less than 1 per cent of their total dry weight. Fluctuations in their amount are explained by their conversion into starch or the reverse change. Hexoses begin to increase in the leaf as soon as saccharose has reached its maximum at 2 p. m., presumably owing to hydrolysis of the saccharose to invert sugar. Dextrin, appearing at the same hour, increases regularly to 6 p. m., when true starch

also reaches a maximum. Both of these then fall rapidly to a minimum of about 0.2 per cent just after midnight, the starch apparently changing directly to dextrose, which shows a corresponding increase in the leaf.

In the stalks, reducing sugars predominate greatly over saccharose. As in the case of the mangold, it is probable that cane sugar is the first sugar formed in the leaf and that it is hydrolyzed by invertase in the veins, midribs, and stalks for the purpose of translocation. As in the mangold, the determination of the true proportions of dextrose and levulose is prevented by the presence of soluble, optically active substances.

Maltose is invariably absent from the leaf of the potato plant and the leaves of other plants which form much starch in the leaf. The degradation of starch in the leaves is thought to be effected by a mixture of enzymes similar to the enzymes of *Aspergillus oryzae*. Maltose is always present in relative excess so that starch is degraded completely to dextrose, the series of changes being starch,  $\rightarrow$  dextrans,  $\rightarrow$  maltose,  $\rightarrow$  dextrose.

Physiological observations on alkaloids, latex, and oxidases in *Papaver somniferum*, R. H. TRUE and W. W. STOCKBERGER (*Amer. Jour. Bot.*, 3 (1916), No. 1, pp. 1-11).—Presenting the results of work done during 1902 to 1905, but afterwards interrupted, the authors state that in the case of *P. somniferum* the oxidase reaction is most active in the upper parts of the plant, especially in the floral structures, capsules, and actively growing parts. In this respect it parallels the distribution of the latex, which in itself is most active. The peroxidase reaction shows less variation in intensity in the different regions. Oxidase seems to be inactivated during the course of its action, as has been noted also in case of Irish potato. This appears to indicate that the oxidase reaction is not caused by a catalyzing agent. Intensity of oxidase reaction roughly paralleled the alkaloid content except in the root, where the latter was relatively the higher. Alkaloids seem not to exist as such in the poppy, but to appear as products of the oxidase action on the constituents present in the latex reacting in the presence of oxygen. Alkaloids of *Atropa belladonna* differ from those of the poppy in that they are found in structures dried out of contact with free oxygen and appear to exist ready formed in the plant.

A substance coagulating inulin and accompanying it in vegetable tissues, J. WOLFF (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 14, pp. 514-516).—The author claims to have found in roots of *Cichorium intybus* and in tubercles of *Dahlia variabilis* a substance which coagulates very actively the juices extracted from these plants and precipitates inulin from the solutions. For this agent the name inulo-coagulase is proposed. After 1 hour of coagulation, the precipitated inulin represented 35 per cent, and after 18 hours 75 per cent of the total quantity.

The constitution of anthocyanins, R. WILLSTÄTTER (*Ber. Deut. Pharm. Gesell.*, 25 (1915), No. 8, pp. 438-449; *abs. in Rev. Gén. Sci.*, 27 (1916), No. 7, p. 199).—Summarizing in this address the results of work recently done by himself and his collaborators, the author states that of about 20 anthocyanins thus far studied, 6 were obtained from fruits, the rest from flowers. The anthocyanins appertain to the oxonium salts. In all cases, these substances were found as glucosids and, by treatment, gave for each case a sugar and a coloring matter. These coloring matters have been termed anthocyanidins. Several are designated as to their origin and are discussed. Chemically, they are said to resemble closely the anthocyanins, which are widely distributed in nature.

Studies on the medium of exchange between roots and soil and among tissues in the plant, P. MAZÉ (*Ann. Inst. Pasteur*, 29 (1915), No. 12, pp. 601-632; 30 (1916), No. 3, pp. 117-140, figs. 3).—Having continued studies previously noted (E. S. R., 31, p. 221), the author states that the mechanism of absorption of nutritive substances from natural or artificial solutions does not include osmosis, the factors apparently operative in the introduction of nutritive substances into circulation being the motility of protoplasm and molecular attraction. The exchanges are possible when the nutritive medium contains all the material necessary to the plant in definite concentration. Incomplete solutions and distilled water introduced directly into the vascular bundles behave as toxic agents. Plasmolysis should be regarded as a phenomenon of coagulation. Osmotic action does not occur between living cells and external media. Absorption of sap is regulated by the chemical activity of the plant. Such phenomena as sap pressure, bleeding, and loss of turgescence are expressions of variation in the pressure within the plant, resulting from want of equilibrium between absorption and transpiration. Phototropic orientation in the stems is due to inequalities of pressure caused by unilateral illumination. Circulation of elaborated sap is assured by the turgescence in assimilating cells, which is periodic, as is sap movement.

It is claimed, in brief, that exchanges between plant and medium and among plant tissues are brought about by the play of mechanical factors, among which the motility of protoplasm predominates by reason of the part it plays in the control of permeability.

The exchange of ions between the roots of *Lupinus albus* and culture solutions containing three nutrient salts, R. H. TRUE and H. H. BARTLETT (*Amer. Jour. Bot.*, 3 (1916), No. 2, pp. 47-57, figs. 3).—In continuance of previous accounts of work with *L. albus* (E. S. R., 34, p. 224), the authors report studies dealing primarily with mixtures of three salts. Two groups of experiments are reported, one employing the nitrates of potassium, calcium, and magnesium, the other employing monopotassium phosphate, calcium nitrate, and magnesium sulphate, each experiment including 36 cultures, each with a concentration of  $140 \text{ N} \times 10^{-6}$ .

It is stated that in general seedlings of *L. albus* absorb more salts from mixtures of potassium, calcium, and magnesium nitrates than from equally concentrated solutions containing one or two of these salts. The solutions of the three nitrates found most favorable to absorption were much inferior to corresponding solutions in which the three anions,  $\text{H}_2\text{PO}_4^-$ ,  $\text{NO}_3^-$ , and  $\text{SO}_4^-$ , were present. The roots absorbed about 50 per cent of the salts from the best solutions of the mixed nitrates and 85 per cent from those of the three anions. In solutions of the mixed nitrates, as in those of the other compounds named, the best absorption occurs when no single ion is greatly in excess, although within a very wide range of variation in proportion the roots absorb with almost equal efficiency.

The antagonistic action of salts in plants, J. G. MASCHHAUPT (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat.* [Netherlands], No. 19 (1916), pp. 1-60, pls. 5, fig. 1).—This is largely a critical discussion of findings and views on the antagonism of salts in nutritive media, listing over 60 contributions on the subject.

Immobility of iron in the plant, P. L. GILE and J. O. CARRERO (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 2, pp. 83-87).—As a result of experiments at the Porto Rico Experiment Station with rice grown in nutrient solutions, the authors have concluded that iron is not transferred from leaf to leaf under conditions where the plant is insufficiently supplied with iron. It is

not claimed that the nontranslocation of iron is a general rule, but the authors' observations on rice and pineapples indicate that iron, after once being transported to the leaves, becomes immobile.

**The poisonous influence of lithium salts on plants,** H. FRERKING (*Flora [Jena]*, n. ser., 8 (1915), No. 4, pp. 449-453).—It is stated that lithium, like magnesium, is poisonous to organisms requiring calcium, but not to calcium-free algæ and fungi. The poisonous influence of lithium is more pronounced than that of magnesium. While the influence of magnesium can be annulled by the employment of calcium salts, that of lithium is only retarded in this way.

**The orientation of primary terrestrial roots with particular reference to the medium in which they are grown,** R. M. HOLMAN (*Amer. Jour. Bot.*, 3 (1916), No. 6, pp. 274-318, figs. 7).—An account is given of a study, principally as relating to the vetch, lupine, and pea, which gave concordant results as regards the behavior of the root tip in relation to the media employed.

It is stated that differences in the amount of water in the media did not affect the behavior of the roots in this regard. Changes of geotonus due to their stay in air were not shown to affect root direction. The failure of the roots in air to reach the vertical appears to be due to the absence of mechanical resistance to the advance of the root tip in this medium. Secondary curvature of the roots in earth, sand, sawdust, sphagnum, or other such media, is complete, because resistance in these media causes passive depression of the root and prevents complete flattening of the tip curvature. Thigmotropism is not a factor in the difference in the behavior of roots in air and in earth or other nonfluid media. Resistance in the medium influences not only secondary but primary curvature, that is, curvature directly following the placing of the root in a position of stimulation.

**The thermometric movements of tree branches at freezing temperatures,** C. C. TROWBRIDGE (*Bul. Torrey Bot. Club*, 43 (1916), No. 1, pp. 29-56, figs. 19).—Summarizing observations which are considered to have made some advance in the study of the influence of temperature on branch movement, the author states that depression of the branches of *Tilia europæa* begins at or just above 32° F. and continues at least as far as 0°, the lowest point at which observations were made. The atmospheric humidity has a negligible influence in this respect. Below 32° there is a stiffening of the branch, offering resistance to the depression. The width of longitudinal frost cracks, after they become established, corresponds somewhat to the temperature below 32°. There are indications that the bending is closely related to the process that produces the frost cracks.

*Platanus orientalis* and *Paulownia tomentosa* show scarcely a trace of the thermometric movement exhibited by the linden.

**The mechanism of movement and the duration of the effect of stimulation in the leaves of Dionæa,** W. H. BROWN (*Amer. Jour. Bot.*, 3 (1916), No. 2, pp. 68-90, fig. 1).—It is stated that leaf closure in *Dionæa* is due largely to an increase on the ventral or convex side of the leaf in cell size, corresponding to a stretching of the cell walls which is soon rendered permanent by growth, and that leaf opening is due to the slow enlargement, likewise corresponding to growth, of cells on the dorsal or concave surface. Stimulation of the leaf is followed by a great acceleration of growth, and apparently immediately by a decrease in osmotic pressure of the dorsal cells resulting in the passage of water from these to those of the ventral region. Starch is deposited abundantly in the dorsal cells soon after closure occurs. Leaves killed in boiling water just after closure open again if transferred through alcohol to xylene and close again when returned to water.

The mechanism of movement in *Dionæa* leaves shows many points of apparent similarity to that of geotropic curvatures. At 21° C., two mechanical stimuli are usually necessary to produce closure, an increase in the time interval requiring increase in the repetitions of the stimuli.

**Sexual variations of the inflorescences and flowers in cultivated *Codium*,** J. CHIFFLOT (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 14, pp. 508-511).—Summing up the results of his observations, the author cites that *Codium*, which is normally monœcious under cultivation, has shown the formation of female flowers from the second generation on male inflorescences, the formation of male flowers from the second generation on female inflorescences, and the formation of inflorescences which were bisexual from the first and of flowers which were hermaphrodite from the first.

**Hybridization between a wild crucifer and a cultivated crucifer with tuberous roots,** Mlle. TROUARD-RIOLE (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 14, pp. 511-513).—It is stated that crossing the wild plant, *Raphanus raphanistrum*, with the cultivated species, *R. sativus*, gave in the first and in the second generation the same product which was obtained from the reciprocal cross. The plants of the first generation were more or less intermediate between the parents. Those of the second generation segregated, about two-thirds or more being tuberous-rooted, while some reverted to the wild type and some showed a mixture of characters. In some cases seeds of the same pod differed greatly. Crossing the wild plant with a hybrid obtained from varieties of cultivated plants gave in the second generation the wild parent, the original hybrid, and intermediate forms suggesting the ancestry of the hybrid parent.

It is thought that hybridization may prove to be an excellent means of accomplishing the tuberization of the wild forms.

**Recolonization of cultivated land allowed to revert to natural conditions,** WINIFRED E. BRENCHLEY and HELEN ADAM (*Jour. Ecology*, 3 (1915), No. 4, pp. 193-210, figs. 2).—This is a study carried on for several years of two wilderness areas left in 1882 with a standing wheat crop, which was permitted to seed itself but which had almost completely died out after four years. The changes which took place during each year and during successive years are discussed in connection with drainage and other factors.

**A text-book of general bacteriology,** E. O. JORDAN (*Philadelphia and London: W. B. Saunders Co., 1916, 5. ed., rev., pp. 669, pl. 1, figs. 177*).—This is the fifth edition of the general text-book by this author, previous editions of which have been noted (E. S. R., 32, p. 371). The present edition has been revised and considerable additions made to certain chapters, particularly those relating to disinfection and the testing of disinfectants, and a new chapter on typhus fever has been inserted.

***Aspergillus niger* group,** C. THOM and J. N. CURRIE (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 1, pp. 1-15).—The recent discovery by the writers that certain species of *Penicillium* are able to form oxalic acid led to a study of the black form species of *Aspergillus*. About 20 strains or species were examined, and all were found to possess in some degree the ability to form oxalic acid when grown in Czapek's solution. Culture experiments with 10 strains led the authors to the conclusion that there are many strains or varieties of black *Aspergillus* which differ markedly in the production of oxalic acid. Comparative studies of the colonies did not correlate the differences in acid production with the morphology of the organisms. The members of this group were found to grow under a wide range of cultural conditions and to exhibit distinct differences, this fact being considered to harmonize with the conclusion of Schiemann that *A. niger* is an unstable or mutating group comparable with *Oenothera* (E. S. R., 28, p. 430).

The colony characters and the morphology of this group are described, after which alphabetical lists of the species, with citations of publications, are given of all the forms which have been described as black or brown.

**Agar agar for bacteriological use, H. A. NOYES** (*Science, n. ser., 44* (1916), No. 1144, pp. 797, 798).—The author claims that the increased acidity due to autoclaving and to titration made in hot solutions can be made the basis of selecting agar agar for laboratory use.

## FIELD CROPS.

[Field crop experiments] (*Kansas Sta. Rpt. 1915, pp. 13, 14, 22, 23, 43, 44*).—Experiments on the effect of seed bed preparation on the yields of wheat (E. S. R., 34, p. 632) showed that the highest yield in 1914 was obtained where the seed bed was double disked in July and plowed deep in August.

Over 940 tests of varieties and head selections of small grain were made, together with rate- and date-of-seeding tests. An improved strain of wheat developed at the station outyielded both Turkey and all local varieties of wheat. Sweet sorghums produced 11.67 tons more silage and 4.57 tons more dry stover than Kafir corn. Sudan grass planted in 7- and 10-inch drills produced three cuttings, with a total of 8.25 tons of field-cured hay per acre.

The development of drought-resistant strains of corn has been continued with 32 third-generation strains segregated from Hybrid 58. The ratio of the weight of leaves and stems to the weight of the root system of milo maize, Kafir corn, and corn was found to be 9.6, 10.9, and 9.6, respectively.

At the Colby substation, 11 varieties of sorghums and 10 varieties of corn were tested. Honey sorghums gave the best returns in forage. The home-grown varieties of corn proved superior to varieties adapted to eastern Kansas.

At the Tribune substation variety tests with sorghums indicate that Dwarf Milo is the highest producer for that section. Experiments with planting corn 84 in. apart instead of 42 in., with the idea of approaching summer fallow conditions but still procuring some return from the soil, gave uniformly higher yields of corn than the closer planting. The home-grown and western-grown varieties gave higher yields than eastern or central Kansas corn.

[Work with field crops at the Belle Fourche reclamation project experiment farm in 1915], B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1915, pp. 1-11, 15-25, figs. 3*).—Continuing previous work (E. S. R., 33, p. 829), a summary of climatic and general agricultural conditions is given.

In the crop rotation experiments with irrigated field crops, after four years' observations the following indications are noted: Alfalfa shows no marked increase in the yield of the following crops, grains following cultivated crops have given better net returns than when following alfalfa and grain, the application of manure has shown a marked increase in the yield of beets and potatoes but not of grains, beets following grain crops give poor results, and early spring seeding of grains has given higher yields and better quality than late spring seeding.

Three pasture grass mixtures for irrigated lands are being tested. Fall irrigation of annual crops was followed by a decrease of yield.

Experiments with alfalfa have been quite extensive, including investigations as to the proper time and method of seeding and the rate of seeding. Late summer seeding and the use of flax as a nurse crop gave good results. About 10 lbs. of good seed per acre was found to be ample.

A number of grain variety tests were conducted by J. H. Martin. Turkey gave the highest yield of any winter wheat variety, and Kubanka of the spring

wheat sorts. White Russian oats gave the highest yield for the oats, and Chevalier II the highest yield for the barleys. Spring emmer yielded at the rate of 58 bu. per acre. The Russian varieties of flax, C. I. Nos. 3 and 19, gave the highest yield of seed. In variety tests with potatoes the late varieties gave decidedly better results than the early varieties. The variety of corn deemed safest to plant is Northwestern Dent. The most desirable distances for corn seem to be 10, 14, and 17 in. apart in the row.

In an experiment undertaken to determine the best time for breaking dry-land sod, early breaking, April to July, gave the best results for the crop following, with no consistent results after the first year.

[Work with field crops on the Huntley reclamation project experiment farm in 1915], D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1915, pp. 1-9, 11-14, 18-21, figs. 3*).—Continuing previous work (*E. S. R.*, 33, p. 429), this bulletin gives a brief outline of the work being conducted on the Huntley reclamation project, including climatic and general agricultural conditions.

The studies on this project are chiefly with irrigated crops. The results of four years' experiments with various crop rotations are reported, the crops used being alfalfa, sugar beets, potatoes, oats, wheat, corn, and flax. The experiments include continuous cropping, and two, three, four, and six year rotations.

In studies with alfalfa to determine the time of harvesting and shrinkage no consistent increase was found from delaying the cutting of the first crop, although the total yield was slightly higher. There was a slight decrease in the amount of shrinkage in the first crop as the growing period was increased, but only a slight variation in the second crop. The average shrinkage on the project during three years has averaged about 76 per cent of the green weight. Some experiments were made in establishing irrigated pastures, a number of grasses being planted separately and in combinations with and without a nurse crop. All the grasses except Kentucky bluegrass gave good results, although further observations are deemed necessary before drawing definite conclusions.

Variety tests included wheat, potatoes, and corn. A preliminary report is given on studies of the losses undergone by sugar beets in the silo.

[Work with field crops on the Scottsbluff reclamation project experiment farm in 1915], F. KNORR (*U. S. Dept. Agr., Bur. Plant Indus., Work Scottsbluff Expt. Farm, 1915, pp. 1-11-13-22, figs. 5*).—This continues previous work (*E. S. R.*, 34, p. 228), and contains a brief discussion of the various projects under way in 1915, with data on weather and crop conditions.

A number of experiments have been undertaken with pasture grasses both when seeded alone and in mixtures. The most promising of the grasses tried are tall oat grass, smooth brome grass, orchard grass, and meadow fescue.

In experiments conducted with crop rotations under irrigated conditions, reported by J. A. Holden, the results to date indicate that there is a decided gain when beets and potatoes follow alfalfa. The yields of both beets and potatoes have also been materially increased by the use of manure. Seeding alfalfa in the fall, after the removal of a small grain crop, has been found feasible.

Variety tests with oats and corn were badly damaged by hail, and no definite conclusions could be drawn. Beloturka yielded highest of the spring wheats and Hannehen of the barleys. Of the stock beets tested Giant Red mangels gave the highest 3-year average yield.

The potato studies included variety tests, seed-stock tests, and irrigation and tillage experiments. In the variety tests No. 4452 and Pearl gave the

highest yields. The seed-stock tests showed immature seed to be distinctly superior for planting. The irrigation and tillage experiments indicated that through a series of years very little difference in yield is to be expected as a result of different methods of irrigation or ditching.

Experiments with sugar beets indicated that deep plowing and deep cultivation are not beneficial to the sugar beet, while they are a source of added expense.

[Work with field crops on the Truckee-Carson reclamation project experiment farm in 1915], F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1915, pp. 1-10, fig. 1*).—This publication continues previous work (*E. S. R., 33, p. 728*), giving in addition to a report on experiments in progress a brief summary of weather conditions, a temperature survey of the project, and a statement as to agricultural conditions.

In pasturing hogs on alfalfa, a net gain of \$44.04 per acre was realized. Experiments have been conducted with corn, but acclimatized varieties have not yet been developed. In variety tests with wheat Little Club and Dicklow have given the highest yields. A number of varieties of barley were tested, with the Coast variety proving far superior to all others. Golden tankard mangels have given larger yields than the long red mangel.

[Work with field crops on the Yuma reclamation project experiment farm in 1915], R. E. BLAIR (*U. S. Dept. Agr., Bur. Plant Indus., Work Yuma Expt. Farm, 1915, pp. 1-15, figs. 2*).—This continues previous work (*E. S. R., 34, p. 229*), including meteorological data and a discussion of the general agricultural conditions.

In work with Durango cotton, it was again found that any check in growth occasioned by drought after the heavy setting of fruit begins is directly reflected in both the yields and the quality of the fiber. A number of varieties of alfalfa were tested but have not been grown a sufficient length of time to give definite results. This was also true of a number of experiments relating to the treatment of alfalfa seed production. Of the 374 strains and varieties of grain sorghums tested, none were found superior to varieties already being grown. Sudan grass has proved to be of value when planted on depleted alfalfa fields or when the hay mixture resulting from such a crop is desired. Sudan grass also furnishes satisfactory pasture when properly irrigated.

A number of miscellaneous forage crops were tested out, among them being forage sorghums, several varieties of millet, flax, and broom corn. Alfalfa showed an increased yield of approximately 2 tons per acre of air-dry hay following a green manure crop.

**Cereal experiments on the Cheyenne Experiment Farm, Archer, Wyoming,** J. W. JONES (*U. S. Dept. Agr. Bul. 430 (1916), pp. 40, figs. 12*).—This bulletin reports a number of cooperative experiments conducted on the Cheyenne Experiment Farm, Archer, Wyo., since 1912. The results are not given as final but as an indication of what might be expected under similar dry-farming conditions. A detailed description of the territory is given, including a comprehensive discussion of the climatic conditions. The plan of the experiment includes variety tests, rate-of-seeding tests, and date-of-seeding tests.

The following varieties of the principal grain crops are regarded as the most promising for the district: Ghirka and Kharkof winter wheat; Kubanka, Erivan, and Marquis spring wheat; Kherson, Sixty-Day, and Swedish Select oats; White Smyrna and Hannehen spring barley; and Montana Common and Select Russian flax. Neither winter nor spring emmer has proved of value. Foxtail and proso millets have given only low yields, and buckwheat does not appear promising. Grain sorghums and corn are deemed promising forage crops for roughage or silage, but apparently have little or no value as forage crops.

Rate of seeding tests for wheat have not been conclusive. Kherson oats sown at the rate of 6 bu. per acre has yielded better than at lower rates, while Svanhals barley has yielded better at 2 and 3 pk. per acre than at higher rates. For flax, 15 lbs. per acre has given the highest average yields.

Early sowing of winter wheat during the first half of September, has given the highest average yields, and the middle of April for spring common wheat and oats. Svanhals barley has yielded best when sown from the middle to the latter part of April, and flax about June 1.

The effect of different nitrogenous fertilizers, especially guanidin nitrate, on oats and mustard, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. scr., 13 (1915), No. 11-12, pp. 141-155, fig. 1*).—A series of pot experiments were conducted in 1913, 1914, and 1915 with lime nitrate, ammonium sulphate, guanidin nitrate, and urea nitrate as fertilizers for oats and mustard. The results of other investigators in experiments with guanidin nitrate are compared with the data reported in tables and discussed at some length.

In the work described guanidin nitrate in 1913 had an injurious effect on the growth of oats but gave a marked increase in the yield of mustard. The average total results with oats and mustard for 1913 and 1914 were in favor of guanidin nitrate as compared with the other nitrogenous substances. It was further observed that lime nitrate gave a large increase in yield the first year, showing little or no residual effect the second year, while ammonium sulphate did not become active until the second year and guanidin nitrate and urea nitrate gave a much more evenly distributed effect, as indicated by the yields for the two years. The residual effect of the guanidin nitrate in 1914 appeared to be a little above the initial effect of the application in 1913.

The results also showed that where mustard and oats were grown together in the same pot, the mustard was capable of using the nitrogen of the guanidin nitrate, while the oats were not. In experiments carried on in 1915 it was shown that oats grown mixed with mustard did not make use to the fullest advantage of the nitrogen supplied by the four different forms, while when grown alone they made good use of the supply of nitrogen from all sources except the guanidin nitrate. In view of these results the relation between the growth of wild mustard and oats in the open field is considered.

Anomalous endosperm development in maize and the problem of bud sports, R. A. EMERSON (*Ztschr. Induktive Abstam. u. Vererbungslehre, 14 (1915), No. 5, pp. 241-259, fig. 1*).—Two anomalous seeds of maize from a cross between colorless parents, one homozygous starchy and the other sugary, are described. One seed, starchy throughout, was about half colorless and half colored purple, while the other, colored purple throughout, presented an endosperm part starchy and part sugary. A description is also given of a third anomalous seed from a cross between colorless seeded and heterozygous, colored-seeded parents, the seed being wholly colored, but half purple and half red.

These seeds are regarded as inexplicable on the hypothesis that the second male nucleus and the fused polar nuclei may each independently develop a part of the endosperm, or on the alternative hypothesis that the second male nucleus may unite with one polar nucleus to produce part of the endosperm, the other polar nucleus developing independently to produce the other part. The seeds are considered explainable on the basis of the hypothesis that subsequent to normal endosperm fertilization there occurs a vegetative segregation of genetic parentage. It is believed to have been shown that if such a segregation occurs it is not a typical Mendelian segregation, as in neither of the three cases all the independently inherited genetic factors present in a heterozygous condition could have been involved. It is suggested that such seeds

may also be regarded as due to a change in genetic constitution rather than to a segregation of genetic factors.

A fourth anomalous maize seed with a small part colored and waxy and the remainder white and horny, which was described by Collins, is regarded as being explainable on the basis of either of the four hypotheses. It is considered of special interest in connection with the segregation and mutation hypotheses because, as is stated, at least two factors instead of a single one are concerned.

The relation of such somatic segregations and mutations in the endosperm of maize to bud sports is considered. Reasons are given for the belief that in certain cases the production of self-color as a bud sport in variegated plants is to be regarded as a somatic mutation rather than as a somatic segregation. The importance of a genetic analysis of material in which bud sports occur, particularly the recessive bud sports, in order to determine whether the factors concerned are in a heterozygous or homozygous condition is pointed out.

Eighteen citations to literature on the subject are appended.

**Yields of different varieties of corn in Illinois,** W. L. BURLISON and O. M. ALLYN (*Illinois Sta. Bul. 191 (1916), pp. 408-424*).—This bulletin reports results of variety tests of corn in Illinois. The highest yielding varieties for the northern, central, and southern sections of Illinois, respectively, were Western Plowman, Reid Yellow Dent, and Funk Ninety Day. A brief history of some of the varieties tested is included in the report.

**Variety tests of corn,** C. B. HUTCHISON, A. R. EVANS, J. C. HACKLEMAN, and E. M. McDONALD (*Missouri Sta. Bul. 143 (1916), pp. 56, figs. 15*).—This bulletin reports the results of variety tests of corn for the 10-year period from 1905-1914, and is supplementary to Bulletin 87 (E. S. R., 23, p. 436). A number of varieties of corn have been tested at the station and from them the more promising varieties chosen for further testing in cooperative experiments throughout the State. The history and description of 12 varieties of corn is given, together with illustrations of each variety. The tests were conducted on seven distinct soil areas, which are described in detail and designated as follows: (1) Black prairie, (2) rolling prairie, (3) level prairie, (4) gray prairie, (5) Ozark border, (6) Ozark uplands, and (7) Missouri lowlands.

The variety tests at Columbia for the 10-year period showed as the leading varieties of white corn Commercial White, Boone County White, Johnson County White, and St. Charles White. The leading varieties of yellow corn were Reid Yellow Dent, Leaming, Cartner, and St. Charles Yellow. The leading varieties for each soil area named above were as follows: (1) and (2), Commercial White and Reid Yellow Dent, (3), (4), and (5), Commercial White and Boone County White, (6), Commercial White and St. Charles White, and (7), Commercial White and Boone County White, except in south-east Missouri, where St. Charles stood first and Boone County White second, and in north Missouri, where Commercial White stood first and St. Charles White second.

**Study of the root system of flax,** A. P. MODESTOV (*Trudy Opytn. Sta. Moskov. Se'sk. Khoz. Inst., No. 1 (1915), pp. 67-84, figs. 11*).—The study of the root systems of a number of pure lines showed that long-stemmed flax as compared with other varieties appeared to have a weaker root system and a more limited root penetration. Of the different soils used in the studies peat stood first and sandy soil second in suitability for root development. A better root growth was developed by means of water culture than in clay or clay soil. With 30 per cent of moisture in the soil, the lowest moisture content in the experiment, the aerial portions of the plants developed best and the roots least, while with

90 per cent, the greatest amount of moisture used, the aerial portions showed the smallest and the roots the largest growth. Under field conditions, the flax being drilled, the roots were found to extend into the soil to a depth of about 20 cm. (7.4 in.) when the plants had from 10 to 12 leaves, of 52 cm. when in bloom, and of 65 cm. when the blossoming period had ended. Deep planting of the seed affected root development adversely.

[The effect of freezing on flax seed], I. SHULOV and V. MOROZOV (*Trudy Opytn. Sta. Moskov. Sel'sk. Khoz. Inst.*, No. 1 (1915), pp. 42-66, figs. 16).—Air-dry seed of flax exposed for one month to a temperature never above  $-2^{\circ}$  R. ( $27.5^{\circ}$  F.) showed no signs of deterioration, while similar seed moistened until swelled suffered a reduced germination through freezing. The results of pot experiments indicated the value of a high moisture content in sandy soil during the early growth of flax.

Changes in specific gravity in their bearing on the starch and dry matter content of potato tubers during the rest period, L. SZÉLL (*Kisérlet. Közlem.*, 18 (1915), No. 5-6, pp. 1020-1029).—Tubers of Richter-Imperator and Up-to-date were stored in a cellar and in a pit out-of-doors. The lot stored in the cellar was examined every two weeks with reference to specific gravity and starch and dry matter content, while the other lot was so examined only at the beginning and close of the storage period.

The specific gravity and relative starch and dry matter value increased in general during the rest period in both varieties of the cellar-stored lot, but decreased in the tubers stored in the out-door pit. The increase in specific gravity followed no definite regularity, which is regarded as due in the first place to such factors as condition of health, respiration, sprouting stage, moisture, temperature, etc., and in the second place to the sources of error in determining specific gravity such as size, shape, degree of maturity, hollowness, of tubers, skin structure, depth of buds, adhesiveness of water to the surface of the tubers, inaccuracies in the method employed, etc., all of which are of irregular influence. Richter-Imperator exhibited a marked tendency to rot, and showed a much greater difference between maximum and minimum specific gravity during the rest period than did Up-to-date. The author does not believe that the methods of determining the specific gravity of potato tubers now employed on farms give reliable results.

[Variety tests with potatoes], E. F. GASKILL (*Massachusetts Sta. Rpt.* 1915, pt. 1, pp. 44a, 45a).—The yields of seven early and eleven late varieties of potatoes are reported. Among the early varieties Early Surprise led with a yield of 314.8 bu. per acre, being followed by Trust Buster with 289.7 bu. Both of these varieties ranked among the five best yielders in all of the three preceding years. The largest yield of the late varieties, 374.5 bu. per acre, was secured from Farmer, with Quick Crop ranking next with 371.3 bu. The late varieties averaged the higher in yield.

Commercial handling, grading, and marketing of potatoes, C. T. MORE and C. R. DORLAND (*U. S. Dept. Agr., Farmers' Bul.* 753 (1916), pp. 40, pl. 1, figs. 18).—This deals with the problems of handling and marketing potato crops, and is meant to be of special interest to commercial growers and shippers. The methods employed in handling the southern early or "new" potatoes and the northern late potatoes are discussed in detail. The use of machine potato diggers and the machine sizing of potatoes are discussed, and the necessity for the establishment and maintenance of definite standards is pointed out. Co-operative marketing organizations are recommended as a means of securing a standardization of the product. Growers are urged to study market conditions and to give careful attention to shipping details. Middlemen are urged to buy potatoes strictly on their merits, thus encouraging careful grading.

The possibilities of sugar beet culture in Washington, I. D. CARDIFF (*Washington Sta. Popular Bul. 105 (1916), pp. 3-8*).—This bulletin is a brief discussion of the sugar beet in Washington, based on studies previously reported (E. S. R., 6, p. 543; 7, p. 762; 9, p. 240; 10, p. 545). Experiments in the Yakima Valley are cited showing that beets can be produced in Washington which test from 15.5 to 17.6 per cent of sugar in the juice and 16.7 per cent in the beet, with an average purity of 85.2 per cent. The value of the sugar beet as a soil cleansing crop is pointed out, together with its adaptability to alkali conditions.

Experiments with Marquis wheat, C. R. BALL and J. A. CLARK (*U. S. Dept. Agr. Bul. 400 (1916), pp. 40, figs. 10*).—This bulletin gives a brief history and description of Marquis wheat, and reports the results of experiments in 13 different States, representing a wide range in soil and climatic conditions, and grouped as follows: (1) The northern Prairie States, or subhumid section; (2) the northern Great Plains States, or semiarid section; (3) the Basin and Coast, or arid areas; and (4) the irrigated districts of the northern Rocky Mountain region and Great Basin areas. The experiments in each section are discussed in detail and the comparative yields tabulated and discussed.

In the northern Prairie States the facts were brought out that where hard red winter wheats of the Crimean group can be grown they outyield any spring wheat varieties, but that Marquis wheat outyields all other spring wheat varieties in that section. The results in the northern Great Plains area show that where winter wheat can be grown it outyields any spring wheat. Among the spring wheats tested the durums outyielded all other groups, although Marquis was superior to all the common spring wheats. In the Basin and Coast areas Marquis wheat did not prove a high yielder, and can not be recommended for any district west of the Rocky Mountains. Under irrigation Marquis has not proved to be a good yielder except in limited experiments east of the Rockies. It is reported as being a first-class milling wheat.

## HORTICULTURE.

Encyclopedia of horticulture, compiled by A. PUCCI (*Encyclopedia Orticola. Turin: Il Giardinaggio [1910-1916], vols. 1-4, pp. 1684, figs. 2067*).—A compiled work comprising a complete illustrated dictionary of all the ornamental, flowering, and economic plants, cultivated or adapted for culture in the gardens of Italy, including also directions for culture, methods of propagation, uses, and illustrated descriptions of all garden equipment, tools, and accessories.

[Horticultural investigations on the Yuma Reclamation Project in 1915], R. E. BLAIR (*U. S. Dept. Agr., Bur. Plant Indus., Work Yuma Expt. Farm, 1915, pp. 15-27, figs. 5*).—A progress report, continuing previous work (E. S. R., 34, p. 231) on cultural and variety tests of orchard and small fruits, vegetables, and ornamentals, including cultural suggestions and recommendations as to varieties based upon experiments conducted on the project.

[Experiments with vegetables on the Truckee-Carson Reclamation Project], F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1915, pp. 10-12*).—Continuing previous work (E. S. R., 33, p. 735), the results are given of variety tests of tomatoes and onions and a fertilizer test with onions.

Manual for the raising of garden seed, L. DÆHNFELDT (*Vejledning i Havefrøavl. Odense: Poul Søndergaards, 1916, pp. 84*).—A treatise on vegetable growing with special reference to seed production.

[Report of] the asparagus substitution, Concord, W. P. BROOKS (*Massachusetts Sta. Rpt. 1915, pt. 1, pp. 16a-22a*).—Investigations leading to the breeding

of a rust-proof asparagus that have been conducted for several years by J. B. Norton (E. S. R., 26, p. 44) indicate that a number of strains of asparagus have been developed which possess both excellent commercial characteristics and in very high degree the capacity to resist attacks of rust. Roots and seeds of these strains are being tested by different growers.

A brief account, together with a summary of results and conclusions, is given of fertilizer experiments with asparagus, C. W. Prescott in charge. A study of the yields and conditions affecting all the fertilizer plats leads to the conclusion that the application of nitrate of soda results in a large increase in the crop. On the light soils where the experiments were conducted nitrate of soda at the rate of 450 lbs. per acre appears to give a more profitable increase in crop, when used in connection with materials supplying abundant potash and phosphoric acid in available forms, than where a larger quantity is used. No definite results have been secured thus far relative to the best season to apply nitrate of soda when used in connection with fertilizers supplying phosphoric acid and potash.

In the experiments in question acid phosphate at the rate of 450 lbs. per acre and muriate of potash at the rate of 262 lbs. per acre have given the best results in combination with nitrate of soda. Muriate of potash appears to be the best source of potash for the asparagus grower. Although rust has not been prevalent during the past three years, observations made by two different observers working independently indicate that the application of nitrate of soda at the close of the cutting season promotes a vigorous growth and seems to increase the capacity of the foliage to resist rust. This appears to be true whether the nitrate is applied one-half in the early spring and the balance at the close of the cutting season or all at the close of the cutting season.

**De Vriesian mutation in the garden bean, *Phaseolus vulgaris*, J. A. HARRIS** (*Proc. Nat. Acad. Sci.*, 2 (1916), No. 6, pp. 317, 318).—In this note the author describes a race of beans now under cultivation at the Station for Experimental Evolution, Cold Spring Harbor, N. Y., in which the whole morphological organization of the seedling has apparently been changed. The new race is also characterized by a high degree of variability. The origin of this race is attributed to de Vriesian mutation (E. S. R., 22, p. 625).

**Marketing and distribution of western muskmelons in 1915, O. W. SCHLEUSSNER and C. W. KITCHIN** (*U. S. Dept. Agr. Bul.* 401 (1916), pp. 38, fig. 1).—In connection with a general study relative to the grading, packing, and marketing of cantaloups (E. S. R., 34, pp. 340, 737) a more detailed study was made of marketing conditions in the irrigated districts of the West. The results of this study are given in the present bulletin. Each region is considered in connection with the history of the industry, marketing arrangements, possibilities of cooperation, and quality and distribution of the crop. Charts are also given showing the distribution of western muskmelons in all markets in 1915, together with net returns to the growers.

**The melons on the market in Paris, J. M. BUISSON** (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 32, pp. 940-945).—The varieties of melons cultivated in the south of France are described.

[Some results of horticultural investigations] (*California Sta. Rpt.* 1916, pp. 44-46, 47, 58, 59, 61).—A brief statement is given of some of the results of horticultural investigations at the station that have a more or less direct bearing on the horticultural industries of the State.

Studies of the oil content of avocados conducted by M. E. Jaffa emphasize the desirability of allowing the fruit to become as mature as possible before marketing in order to increase the fat content. The fat content at maturity varied from a maximum of 27 per cent to a minimum of 5 per cent, thus show-

ing the importance of selection as to variety if the percentage of oil is to be taken into consideration. Demonstrations made by Coit show that the Babcock test may be used for the determination of fat in avocados with sufficient accuracy for a preliminary comparison of the value of seedlings.

Preliminary examinations by Jaffa of olives labeled "ripe olives" show a variation in the fat content much greater than can be ascribed to the difference in varieties or to the loss of oil in the pickling process. The wide range is considered to be largely due to the processing and marketing of immature olives in place of ripe olives.

The more important practical results secured from grape investigations conducted by F. T. Bioletti are summarized. The plum and prune pollination investigations carried on by A. H. Hendrickson show definitely that all varieties of the Japanese prune or plum (*Prunus triflora*) are self-sterile, with the possible exception of the Climax. The varieties of this group seem to cross-pollinate readily. Of the European varieties of plum, *P. domestica*, Tragedy, and Clyman show distinct evidence of self-sterility. Of the prunes, French and Sugar prunes appear to be self-sterile to some extent. Robe de Sergeant and Imperial prunes are distinctly self-sterile. Imperial, French, and Sugar prunes seem to cross-pollinate satisfactorily.

In similar observations on almonds made by W. P. Tufts during 1916 13 varieties, including practically all grown on a commercial scale in California, proved to be wholly self-sterile under conditions existing at the University Farm. Two of the leading varieties, Nonpareil and I X L, were found to be intersterile as well as self-sterile. Ne Plus Ultra was satisfactory as an inter-pollenizer with both I X L and Nonpareil.

The leading commercial varieties of cherries grown in the State, including Napoleon, Lambert, Bing, Black Tartarian, and Black Republican, were found to be self-sterile. There is distinct evidence of intersterility between several varieties, such as Bing and Napoleon. The best pollenizers for cherries in the State have not been worked out thus far.

Preliminary investigations conducted by W. L. Howard and Tufts indicate that fruit bud formation under interior valley conditions, at least in California, occurs from one to two months later than in other sections of the United States where studies of this phase of fruit production have been made.

Observations on the varieties of pecans planted in California indicate that the season is too short for pecan culture in the northern and middle coastal regions. In the interior valleys and in the southern coast counties many pecans have been found to ripen their crops without difficulty. Many other pecan seedlings failed to mature their crops in the southern coast counties.

A study of the Weather Bureau records in various parts of California by A. E. Way for determination of maturity of oranges have led him to conclude that the factor that chiefly affects maturity is not soil type, irrigation, fertilization, heat, or light units alone but the ratio between the total heat units and relative humidity of the atmosphere.

A paper on the results of experiments in fertilizing citrus groves has been noted from another source (E. S. R., 35, p. 448). The experiments in using winter cover crops as green manures in citrus groves continue to emphasize the importance of this practice in citrus culture (E. S. R., 33, p. 642). The use of bitter clover (*Melilotus indica*), advocated by the station as a result of these experiments, is becoming very general. The experimental plats on the station grounds show marked increases in vigor and yield where green manures have been used.

In a preliminary study of a seedling Santa Barbara soft-shell walnut grove being conducted by L. D. Batchelor wide variation was found to exist with reference to production of the trees, their susceptibility to blight, size, season of leafing out in the spring, and the season at which the trees become dormant in the fall. Trees which retain their leaves late in the fall are better producers than those which drop their leaves early. Very little relationship occurs between the season of foliation in the spring and the crop production. Likewise little or no relationship exists between the prevalence of blight and either the season of dormancy or the season of foliation. The size and vigor of the tree does not appear to influence the prevalence of the blight. There is a marked correlation between the size of the tree and its production. In cooperation with the walnut growers selections have been made of 16 promising seedling trees scattered about the State that are known to be specially heavy producers and more resistant to blight than the average.

[Orchard trees and small fruits on the Huntley Reclamation Project], D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1915, p. 22*).—A brief statement relative to variety tests of orchard trees and small fruits being conducted on the project and continuing previous work (*E. S. R., 33, p. 429*).

Modern propagation of tree fruits, B. S. BROWN (*New York: John Wiley & Sons, Inc., 1916, pp. XI+174, figs. 75*).—A treatise on the propagation of fruit trees, in which are considered those practices of propagation which are accepted as the most important by the orchardist and commercial nurseryman. The subject matter is presented under the general headings of seed for propagation, growing the seedlings, the nursery, budding operations, grafting operations, propagation by cuttings, the after treatment of nursery stock, and some general considerations.

Some figures on the cost of bringing orchards into bearing (*Mo. Bul. Com. Hort. Cal., 5 (1916), No. 10, pp. 368-371*).—Records are submitted by a number of growers in California showing the cost of bringing orchards of different kinds of fruits and of different sizes into bearing.

Some improvements in the packing and transport of fruit in India, A. and GABRIELLE L. C. HOWARD (*Fruit Expt. Sta. Quetta Bul. 2 (1915), pp. 21, figs. 6*).—This paper discusses briefly the present methods of packing and transporting fruit in India and calls attention to some of the improvements that can be made along this line as developed with experiments conducted at Pusa and Quetta.

Notes on Pomaceæ of upper South Carolina, W. W. ASHE (*Bul. Charleston Mus., 12 (1916), No. 5, pp. 37-43*).—The author describes species of crab apples and hawthornes observed in upper South Carolina. A number of new species are included.

The pollination of the pomaceous fruits.—III, Gross vascular anatomy of the apple, E. J. KRAUS and G. S. RALSTON (*Oregon Sta. Bul. 138 (1916), pp. 4-12, pls. 8*).—This is the third of a series dealing with the pollination of pomaceous fruits (*E. S. R., 33, p. 838*).

In the present paper the authors discuss and illustrate the anatomy of the pedicel, toral, and carpellary systems of the apple as observed in a study of the Yellow Newtown variety.

The fruiting of trees in consecutive seasons, S. PICKERING (*Jour. Agr. Sci. [England], 8 (1916), No. 1, pp. 131-135*).—A popular review of the results secured in the investigations at the Woburn Experimental Fruit Farm (*E. S. R., 35, p. 37*).

Peach growing in Ontario, F. M. CLEMENT and A. G. HARRIS (*Ontario Dept. Agr. Bul. 241 (1916), pp. 51, figs. 48*).—An account of peach growing in Ontario,

including the history of the industry, varieties, culture, harvesting, and marketing. A paper on the More Important Insects and Diseases Attacking Peach Trees (pp. 41-51), by L. Caesar and J. E. Howitt, is also included.

The persimmon in California, S. FUJII (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 10, pp. 362-367, figs. 7).—A number of Japanese persimmons adapted for culture in California are described.

State bog report, H. J. FRANKLIN (*Ann. Rpt. Cape Cod Cranberry Growers' Assoc.*, 28 (1915), pp. 13-32).—A report on the work at the Massachusetts state cranberry bog for the year 1915, the substance of which has been noted from another source (E. S. R., 36, pp. 43, 51, 54).

Is the hybrid origin of the loganberry a myth? (*Jour. Heredity*, 7 (1916), No. 11, pp. 504-507, fig. 1).—In this article some evidence is presented to show that the loganberry has behaved on the whole as a true species rather than as a hybrid of the blackberry and raspberry.

Methods of reproducing grapes by long cuttings and short cuttings, P. J. RÍCOME (*Los Proccdimientos de Reproduccion de la Vid, Estacas Largas y Estacas Cortas. Lima, Peru: Govt.*, 1916, pp. 26, pls. 4).—The author gives the results of two years' experiments in reproducing grapes. Briefly summarized the use of one-year cuttings completely covered in the ground gave the best results in coastal Peru.

Some recent operations and experiments with bud variations, A. D. SHAMEL (*Cal. Citrogr.*, 2 (1916), No. 1, pp. 14-16, figs. 3).—Essentially noted from other sources (E. S. R., 34, p. 639).

Pruning the Washington navel orange, R. W. HODGSON (*Univ. Cal. Jour. Agr.*, 4 (1916), No. 2, pp. 38-40, figs. 4).—Observations are presented on methods of pruning Washington navel oranges, based upon the results of four seasons' actual pruning and a study of the various pruning systems practiced by growers.

Report on manurial experiments (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. Dominica, 1915-16, pp. 14-28*).—A progress report on manurial experiments with cacao and limes in Dominica (E. S. R., 34, p. 438). The work with limes continues to show satisfactory growth, accompanied by a substantial increase in profit, on the complete manure plat as well as a slow but steady improvement in the yield and general appearance of trees on the mulch plat. The work with cacao continues to show a decided advantage over fertilizers in favor of the mulch plats.

[Cacao experiments, 1914-15], J. DE VERTEUIL (*Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 4, pp. 111-142, pls. 9*).—This is the usual progress report for the year ended August 31, 1915, relative to manurial, shade, pruning, and natural yield experiments being conducted in a number of plantations in Trinidad (E. S. R., 33, p. 738), including also data on manurial experiments with cacao and rubber in Tobago. No conclusions have thus far been drawn from the work as a whole. With reference to natural yield experiments it has been observed, generally speaking, that the heavy bearing trees of the first year have continued to be heavy bearers, and that the poor-yielding trees have remained poor during subsequent years.

Cacao, J. E. VAN DER LAAT (*Pub. Dept. Agr. Costa Rica No. 4 (1916), pp. 23*).—A practical treatise on the culture and preparation of cacao for market.

[Experiments with coffee in Surinam], E. VAN DRENT (*Dept. Landb. Suriname Verslag, 1915, pp. 50-61*).—The various species of coffee being tested at the Government Culture Garden are listed, and data are given on the yields during 1915 of the various trees of Uganda, Canephora, Quillou, and Excelsa coffee being tested.

The cultivation and preparation of coffee for the market, J. P. UGARTE (1916, 2. ed., pp. 101, pls. 19, figs. 2).—This work comprises a description of the various operations in connection with coffee planting and culture; information relative to methods of coffee pulping, fermenting, washing, drying, hulling, polishing, and grading, as well as general remarks based on practical experience acquired in Mexico, Central America, etc.

New and successful method of rooting date palm offshoots, J. E. COIT (Univ. Cal. Jour. Agr., 4 (1916), No. 2, pp. 49, 60, 61, figs. 2).—The author here describes a method of rooting date palm offshoots developed by B. Drummond of the Bureau of Plant Industry of the U. S. Department of Agriculture in cooperation with J. Northrop of Indio, Cal.

The method consists essentially in the use of a propagating house covered with canvas instead of glass and with no ventilation whatever. This type of house was found to be much more economical than a glass house and has yielded satisfactory results to a number of growers. It prevents excessive drying by wind and sun, maintains an atmosphere of rather dense humidity above the plants, and at the same time a high temperature, thus furnishing the best conditions for rooting date palm offshoots. In some instances many old offshoots which had been set in the field for one or even two years and had shown no signs of life have, when placed in the canvas houses, thrown out large fresh green leaves and vigorous roots within six or eight weeks.

Colonial plants.—Perfume, tincture, and tannin plants, and tobacco, H. JUMELLE (*Les Cultures Coloniales—Plantes a Parfums, a Colorants, et a Tannins, Tabac. Paris: J. B. Baillièrè & Sons, 1916, 2. rev. ed., vol. 8, pp. 112, figs. 25*).—This is part 8 of the author's revised work (E. S. R., 34, p. 838). The present part discusses the various perfume, tincture, and tannin plants and tobacco with reference to their botany, exploitation, culture, and utilization.

Colonial plants.—Industrial plants, H. JUMELLE (*Les Cultures Coloniales—Plantes Industrielles. Paris: J. B. Baillièrè & Sons, 1916, rev. and enl. ed., pp. 112+118+119+112+XX, figs. 146*).—The present volume comprises parts 5 to 8 of the author's work on colonial plants which have previously been issued separately (see above abstract). The plants included are oil-yielding plants, textile plants, and plants yielding rubber, caoutchouc, lac, perfumes, tinctures, and tannins, and tobacco.

Sources of supply of hazelnuts (*Bul. Imp. Inst. [So. Kensington], 14 (1916), No. 2, pp. 261-267*).—A short statistical account relative to the production and supply of hazelnuts in different countries.

Iris breeding (*Jour. Heredity, 7 (1916), No. 11, pp. 502, 503*).—This paper includes a contribution by Grace Sturtevant on the technique of iris breeding, together with some descriptive notes on iris hybrids secured in breeding work conducted by W. R. Dykes and by S. Mottet.

My garden, LOUISE B. WILDER (*Garden City, N. Y.: Doubleday, Page & Co., 1916, pp. XIX+308, pls. 8*).—An account of the author's experience in planning and making an ornamental garden, including descriptive notes on the various plantings as they appear throughout the season, information relative to methods of propagation, culture, and care, the adaptation of plants to different situations, and the merits of different varieties. Lists are given of the best annuals and of plants for special situations, the wild garden, herb garden, and wall garden, and references are made to a number of works dealing with gardens and plant material.

My garden in spring, E. A. BOWLES (*London: T. C. & E. C. Jack, 1914, pp. XX+308, pls. 40*).—This is the first of a series of three books, edited by R. H. Pearson, which is primarily descriptive of the plant material in the author's

garden in Middlesex, England. The present volume deals with the several parts of the garden in their spring aspects.

**My garden in summer**, E. A. BOWLES (*London: T. C. & E. C. Jack, 1914, pp. VIII+316, pls. 40*).—A work similar to the above, descriptive of the author's garden in its summer aspects.

**My garden in autumn and winter**, E. A. BOWLES (*London: T. C. & E. C. Jack, 1915, pp. VIII+272, pls. 40*).—A work similar to the above, descriptive of the author's garden in its autumn and winter aspects.

**Beautifying the rural home**, C. N. KEYSER and E. G. WELCH (*Ga. State Col. Agr. Circ. 30 (1916), pp. 8, figs. 8*).—This circular contains pictures and plans of a model farmstead of 2.25 acres and a model town lot of 0.9 acre in extent.

## FORESTRY.

**British forestry**, E. P. STEBBING (*London: John Murray, 1916, pp. XXV+257, pls. 13*).—An economic discussion of the present status and future outlook of forestry in Great Britain. The subject matter is presented under the general headings of a national planting scheme, British timber supplies and the forests of Russia, timber supplies and the war, and the employment of women in forestry.

**Forest problems and economic development in South America**, R. ZON (*Proc. Soc. Amer. Foresters, 11 (1916), No. 4, pp. 375-385*).—A paper on this subject read before the Second Pan-American Scientific Congress, at Washington, D. C., January 5, 1916 (E. S. R., 34, p. 306).

**South American forests**, H. M. CURRAN (*Proc. Soc. Amer. Foresters, 11 (1916), No. 4, pp. 369-374*).—A short general description of the principal forest types of South America.

[**Trees and shrubs on the Belle Fourche Reclamation Project**], B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1915, pp. 25, 26, fig. 1*).—A brief statement relative to the condition of trees and shrubs under test on the Belle Fourche Experiment Farm in 1915 and continuing previous work (E. S. R., 33, p. 837).

The tests indicate that for a quick-growing windbreak Carolina and Norway poplars are probably the best. It is recommended that these be planted in alternate rows with green ash, white elm, and honey locust, the windbreak to be finished on each side with Russian oleaster and Siberian pea tree. A list is also given of shrubs for ornamental planting that seem to be suitable for local conditions and climate.

**Tree distribution under the Kinkaid Act, 1911** (*U. S. Dept. Agr., Forest Serv., Tree Distribution Under Kinkaid Act, 1916, rev. ed., pp. 13, figs. 6*).—This publication explains the provision for the free distribution of young trees in western Nebraska from the Nebraska National Forest, as annually provided for in the Federal agricultural appropriation act; briefly discusses the characteristics of trees considered suitable for planting; and gives illustrated directions for growing and planting the trees, together with instructions for securing trees for planting.

**Forest Service silviculture plans**, T. S. WOOLSEY, JR. (*Proc. Soc. Amer. Foresters, 11 (1916), No. 1, pp. 1-16*).—In this article the author comments in detail on the silviculture section of the Forest Service working plans and offers suggestions relative to the development of working plans.

**Notes on forest cover and snow retention on the east slope of the Front Range in Colorado**, N. DEW. BETTS (*Proc. Soc. Amer. Foresters, 11 (1916), No. 1, pp. 27-32, figs. 4*).—The author presents some data on results of observations made in Colorado during 1911 and 1912 with the view of calling attention to

the effect of the spruce type of forest in retaining the snow at high altitudes. It is further pointed out that the advantage of the treeless catch basins lying above the timber line for the formation and retention of large snow drifts is due, not to the fact that they are treeless, but to their location in regard to precipitation, wind, and summer climate. The part that the present stands of spruce play in keeping the snow as high as possible is the important point, and has a direct bearing on the value of reforesting the many burned areas in the high mountains at the head of streams.

**Evaporation and soil moisture in relation to plant succession**, C. F. KOSTAIN (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 430-433).—A review of some literature on the subject.

**Silvicultural notes on western larch**, J. A. LARSEN (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 434-440).—Notes on the growth performance of western larch in mixed stands and its adaptation to different sites and soils.

**Slash pine, an important second-growth tree**, W. R. MATTOON (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 405-416, fig. 1).—An account of the slash pine (*Pinus caribæa*) with reference to its present range of distribution, factors of local distribution, important silvicultural characteristics, value of lumber, and production of turpentine.

**The natural root grafting of conifers**, H. S. NEWINS (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 394-404, figs. 6).—Studies conducted by the author relative to the natural root grafting of conifers led to the conclusion that this phenomenon is common only between trees having an affinity for each other, and is due moreover to pressure exerted by two or more opposing roots in combination with a number of physical factors. The phenomenon of the "growing stump" as observed among conifers is most common with Douglas fir and is the result of conjunctive symbiosis which is made possible by the natural root graft of the stump with a living tree.

**Chemistry as an aid in the identification of species**, A. W. SCHORGER (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 1, pp. 33-39).—The author cites authorities to show that although the oil from the same species may differ in quantity in different localities, the quality remains identical. The results are also given of an examination of the volatile oils from a number of western species of pine, with particular reference to distinguishing between Jeffrey pine, western yellow pine, and "cross variety" western yellow pine, which species are usually hard to distinguish between in the field.

"The data obtained by chemical analyses have shown that 'cross variety' western yellow pine should be referred to *Pinus ponderosa* and that there is no relation between 'cross variety' pine and *P. jeffreyi*. There are also indications of the occurrence in California of typical specimens of *P. ponderosa scopulorum*. The oils from *P. ponderosa* and *P. ponderosa scopulorum* are distinctly different and justify the separation into two forms. Oils from western yellow pine from Arizona and Colorado agree closely, while oils examined from the State of Washington agree with the typical oils from *P. ponderosa* of California, showing that the defined difference in geographical distribution of the species and its variety is supported by a difference in the composition of the oils."

**Comparative test of the Klaussner and Forest Service standard hypsometers**, D. K. NOYES (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 417-424).—The test here noted was conducted on a number of permanent sample plats established by the Forest Service of the U. S. Department of Agriculture in California.

The results in general showed that the Klaussner hypsometer is only from 60 to 80 per cent as fast as the Forest Service hypsometer, depending on the size

of the timber encountered. Nevertheless, because of other advantages here discussed the Klaussner hypsometer was adopted for work on the project.

**Utilization and round-edge lumber**, R. T. FISHER (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 4, pp. 386-393).—An account of the close utilization of saw timber in the woodlot region of central New England.

**The utilization of a tropical forest**, G. P. AHERN (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 1, pp. 17-26).—A paper on this subject delivered before the Society of American Foresters, December 16, 1915.

## DISEASES OF PLANTS.

**Department of botany**, A. V. OSMUN (*Massachusetts Sta. Rpt. 1915, pt. 1, pp. 62a-64a*).—A brief account is given of investigations of plant diseases during the year covered by this administrative report.

The mosaic disease of sweet peas, ring spot of cauliflower caused by *Mycosphaerella brassicicola*, and a leaf spot of digitalis due to an undetermined species of *Colletotrichum* are reported as not having been previously observed in the State. Notes are also given on the silver scurf, late blight, and *Rhizoctonia* disease of potatoes, together with reports of diseases of a number of other economic plants. The damage done by the late blight is said to have been especially heavy, but it was noticed that those fields repeatedly sprayed with Bordeaux mixture showed little loss.

Some culture experiments on the production of powdery scab of potato were conducted in which plantings of infected tubers were made on the station plats and on soil from these plats sent to Maine. No evidence of the powdery scab was obtained from the station plantings, but the disease did develop on the soil sent to Maine. The results are thought to indicate that climate plays an important part in the distribution of this disease.

Heavy losses to tobacco growers in the Connecticut Valley were reported as resulting from some obscure troubles which are not yet determined but which are believed to be related in some way to the nutrition of the plants.

The white pine blister rust is said to occur in 8 of the 14 counties of the State, and it has assumed serious proportions in western Massachusetts. Investigations of certain phases of the life history of the fungus with a view to obtaining control have been inaugurated.

**Five undescribed species of *Ravenelia***, W. H. LONG (*Bot. Gaz.*, 61 (1916), No. 5, pp. 417-424).—The author describes as new species *R. ræmeriana* on *Acacia ræmeriana* at San Marcos, Tex.; *R. morongia* on *Morongia uncinata* at Austin, Tex.; *R. thornberiana* on *A. constricta paucispina* at El Paso, Tex.; *R. reticulata* on *Calliandra reticulata* at Divide, Ariz.; and *R. annulata* on *Lysiloma latisiliqua* at Miami, Fla.

***Rhizoctonia solani* in relation to the "Mopopilz" and the "Vermehrungspilz,"** B. M. DUGGAR (*Ann. Missouri Bot. Gard.*, 3 (1916), No. 1, pp. 1-10).—The author considers it safe to conclude that the seed bed fungus common in Germany and France is identical with the damping-off fungus which has been studied in this country since 1892, some contributions regarding which are discussed. Evidence is offered in favor of the view that this fungus is identical with that which causes the mopo disease of cinchona ascribed by Rant to *Moniliopsis aderholdii* (E. S. R., 34, p. 749) and herein asserted to be the same as *R. solani*.

**Cereal disease resistance** (*Kansas Sta. Rpt. 1915, p. 15*).—Attention is called to a method devised by this station to secure under field conditions the infection of various cereals.

In connection with studies of disease resistance, a variety of emmer has been found which is not subject to rust attack, while another was only slightly attacked. A number of  $F_1$  and  $F_2$  generations of wheat hybrids are being tested for resistance to rust (*Puccinia graminis tritici*). Observations made on 119 varieties of winter wheat showed infection with leaf rust (*P. rubigo-vera tritici*) varying from 5 to 90 per cent. Histological studies are said to be in progress to determine the cause of immunity to smut in milo maize and of susceptibility to this smut in other sorghums. Studies are being conducted on the life habits of the smut on maize and on the varietal resistance due to environmental conditions or to specific characteristics in the host.

**Rye smut**, E. C. STAKMAN and M. N. LEVINE (*Minnesota Sta. Bul.* 160 (1916), pp. 3-19, figs. 6).—A disease of rye variously known as stem smut, stalk smut, and stripe smut, due to the fungus *Urocystis occulta*, is described. The disease is said to cause serious losses in Minnesota, in some localities from 5 to 40 per cent of the plants in the field being infected. The spores are said to live over in the seed or soil, and seed treatment with formaldehyde and planting in clean soil are recommended as control measures. Rotation of crops is advised in order that the fungus may be eliminated from the soil.

**The determination of ustilaginous spores in flour, bran, and cereals**, G. BREDEMANN (*Landw. Vers. Stat.*, 87 (1915), No. 4-5, pp. 241-250).—The author reports further analytical data obtained by the method previously noted (E. S. R., 26, p. 408) and concludes that it yields truer and more reliable, not only relative but positive, results than the procedure described by Gr6h (E. S. R., 27, p. 310).

**The quantitative determination of smut spores in bran**, G. BREDEMANN (*Arch. Chem. u. Mikros.*, 8 (1915), No. 4, pp. 87-95).—Tests described are considered to prove the reliability of methods for spore estimation employed by the author (E. S. R., 26, p. 408).

**The Texas root rot fungus and its conidial stage**, B. M. DUGGAR (*Ann. Missouri Bot. Gard.*, 3 (1916), No. 1, pp. 11-23, figs. 5).—Having made a study of the cotton root rot which is common in many portions of Texas, the author describes the causal organism, which, with some modifications of form and habit, attacks also an unknown but probably large number of native plants in that State, under the new combination *Phymatotrichum omnivorum*, retaining the specific name applied thereto by Shear (E. S. R., 19, p. 446).

**Spongospora on the roots of the potato and on seven other new hosts**, I. E. MELHUS and J. ROSENBAUM (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 108).—This fungus, which is commonly considered to infect the tubers, the authors found in greenhouse experiments to involve all the underground parts of the plants. Later, this condition was found to prevail in the field also.

The authors' investigations have shown that *Spongospora*, in addition to infecting the potato, attacks the tomato and six species of *Solanum*, *S. commercioni*, *S. ciliatum*, *S. marginatum*, *S. mammosum*, *S. hamotocladum*, and *S. warsewiczii*.

**Meteorology and late blight of potatoes**, C. R. ORTON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 107).—From a study of the meteorological conditions in connection with the late blight of potatoes at the Pennsylvania Experiment Station, the author claims that precipitation alone has little if any bearing on the problem. Atmospheric temperatures alone or when correlated with precipitation do not appear to have much relation to the outbreak of disease. Humidity and soil temperature are believed to bear directly upon the subject.

**A Fusarium tuber and stem rot of potato**, R. J. HASKELL (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 106, 107).—The author reports having isolated from the fibrovascular bundles of potato tubers a *Fusarium* which produces a

very virulent stem and tuber rot. The organism appears to be related to, if not identical with, *F. eumartii*.

Crop yield, tuber color, and leaf roll of potato in relation to soil and fertilizer, J. AHR, C. MAYR, and WÖRLE (*Fühling's Landw. Ztg.*, 64 (1915), No. 17-18, pp. 425-452, figs. 3).—Giving details and discussion of several series of experiments dealing mainly with nutritive materials as affecting potato culture, the authors state, in reply to the statements of Schander (E. S. R., 33, p. 433), that apparently without reference to the degree of maturity or the kind of fertilizer, the dark colored tubers of the variety Wohltmann showed in one year under the influence of given soil conditions a lighter color of skin and a corresponding alteration in the growth of the plant, its resistance to disease, and its productivity. Apparently, there is no connection between the appearance of leaf roll and the coloration of the potato, the latter appearing to depend principally upon the physical properties of the soil, which the experiments show to be the preponderating influence in potato production.

Field studies on the Rhizoctonia of the potato, M. T. COOK and H. C. LINT (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 106).—Rhizoctonia diseases of potatoes are said to have been severe in New Jersey in 1915, the attack of the fungus causing poor germination, brown stem, curly leaf, dwarfing, aerial potatoes, and little potatoes, with resultant poor stands, reduced yields, and, in some cases, complete loss of the crop. The results obtained from seed treatment were variable, but corrosive sublimate proved much better than formaldehyde for the prevention of these troubles.

The effect of Bordeaux mixture on the potato plant, B. F. LUTMAN (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 108).—Basing his conclusions on seven years' investigations in this country and one in Germany, the author believes that the beneficial effects of Bordeaux mixture can be ascribed to the prevention of the early appearance of tipburn and of the greater part of flea beetle injury. Of these two effects the former is considered the more important, as tipburn advances much more slowly on sprayed than on unsprayed plants. The cause of this retardation is thought to be some sort of chemical union between the chlorophyll and the copper compounds. Sprayed plants unaffected by tipburn are not found to produce more starch per plant than unsprayed ones.

Biochemical study of root rot in sugar beets, J. BODNÁR (*Ztschr. Pflanzenkrank.*, 25 (1915), No. 6, pp. 321-325).—The substance of this report has been noted previously from another source (E. S. R., 34, p. 52).

Fruit tree diseases of southern Ontario, W. A. McCUBBIN (*Canada Expt. Farms Bul.* 24, 2. ser. (1915), pp. 77, figs. 70).—Popular accounts are given of the diseases of fruit trees known to occur in Ontario. The fungi causing these diseases are described and suggestions given for control measures.

Temperature relations of apple rot fungi, C. BROOKS and J. S. COOLEY (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 111).—According to the authors, apples with natural infections of bitter rot and black rot were stored at various temperatures. The development of bitter rot was slow at 15, rapid at 25, and slow at 30° C. It was completely inhibited at 0, 5, and 10°, but developed rapidly when the apples were removed to a temperature of 25°.

Black rot developed rapidly at 25°, but it had made little progress at 10° at the end of ten days. After two months' storage, there was considerable development even at 0°.

The temperature relations for growth of a number of other fungi occurring on stored apples are also reported upon.

Black root rot of apple, H. R. FULTON and R. O. CROMWELL (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 110).—A form of root rot is briefly described, as it has been observed as serious in a number of places in Pennsylvania and

North Carolina. Pure cultures of the fungus have been made, but the fruiting bodies have not been discovered. The disease is readily produced by introducing the mycelium into bark wounds in the roots, and it is said to develop quite rapidly. The fungus differs in many respects from those ordinarily recognized as root-destroying forms. Its identity has not been determined.

Some effects of the black rot fungus, *Sphæropsis malorum*, upon the chemical composition of the apple, C. W. CULPEPPER, A. C. FOSTER, and J. S. CALDWELL (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 1, pp. 17-40).—A report is given of an investigation, conducted mainly at the Alabama Experiment Station, to determine the changes in the chemical composition of apples attacked by the black rot organism. Comparisons were made of sound, mature Red Astrachan apples with fruit of the same variety in two stages of decay.

A slight loss of water and a considerable reduction in the amount of total solids were found in the completely decayed fruit. There was also a marked reduction, concurrent with the progress of the disease, in the amount of the constituents removed by successive extractions of the pulp with alcohol, ether, and water. A decrease, followed by an increase, was noticed in the absolute, as well as in the relative, amounts of the lipid constituents extracted by alcohol or ether and precipitated from water emulsion by chloroform.

The nitrogen extracted by alcohol, water, and ether steadily decreased with the progress of the disease, as did also the ammonia. The protein nitrogen increased steadily with the progress of the disease, but there was a small decrease in the total nitrogen due to the complete decomposition of some of the nitrogenous constituents with the escape of ammonia.

Phosphorus in both lipid and insoluble fractions was materially decreased in the half-decayed fruit. In the completely decayed fruit there was a further reduction in the lipid phosphorus, an increase in soluble phosphorus, and a very large increase in insoluble or protein phosphorus.

A steady transfer of mineral elements from the insoluble to the soluble fraction was observed. A rapid decrease took place in the content of reducing sugars, disaccharids, and lipid sugars as the disease proceeded. Of these carbohydrates, the disaccharids were least completely utilized. Starch was not attacked by the fungus, its amount remaining unchanged throughout the progress of the decay. There was a progressive decrease in the acid content of the fruits, and with the advance of the disease a large increase in the alcohol content occurred.

Blister spot of apples, D. H. ROSE (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 110).—The author reports upon a disease of apples observed in the summer of 1915, which, it is believed, has not yet been described.

The disease is characterized by the appearance of nearly circular, sometimes irregularly lobed, shallow blisters varying in color from light brown to black and in diameter from 1 to 5 mm. The organism has been isolated, and inoculations made by needle punctures have resulted in typical blister spots in about two weeks on Early Melon, Ishewold, Yellow Newton, and Jonathan.

On the flower wilt and young fruit rot of the apple tree caused by *Sclerotinia mali* n. sp., Y. TAKAHASHI (*Bot. Mag. [Tokyo]*, 29 (1915), No. 343, pp. 217-223).—In this paper the author has described the conidial and ascosporeous stages of the fungus causing flower wilt and fruit rot of the apple, the morphological characters of which are said to resemble closely those of *S. kusanoi*, but which gave negative results on inoculation into cherry trees. The fungus is considered a new species and has received the name *S. mali*.

Apple scald, C. BROOKS and J. S. COOLEY (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 110, 111).—Experiments are reported upon which are said to indicate

that humidity is more important than carbon dioxide in the amount of scald in apples in storage. The results obtained from the investigations are said to suggest the importance of a relatively low temperature and an open pack for the prevention of scald.

**Brown blotch of the pear**, G. W. MARTIN (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 111, 112).—A brown blotch of the pear which is said to cause a serious disfigurement of the fruit is reported as having been present in the orchards of New Jersey for a number of years. This pear disease seems to have been confused with russeting, which is characteristic of many varieties of pears, and had not been recognized as a pathological condition. It is said to be due to a fungus which is identical with one described under the name *Macrosporium sydowianum* as causing a similar disease in Italy.

It is claimed that the disease may be readily controlled by two late sprayings.

**The parasitism of *Valsa leucostoma***, R. C. WALTON and D. C. BABCOCK (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 112, 113).—Inoculations with this fungus resulted in 100 per cent infection on the trunks and larger branches of peach trees, cankers being formed in about a month's time. No infections were secured where mycelium was placed over lenticels without wounds. Inoculations of both green and ripe peach fruit gave 94 per cent infection, while plum fruit inoculated gave 97 per cent. Inoculations made in tips of peach branches gave 85 per cent infection, while all checks remained free from disease.

**A preliminary report on investigations of leaf spot of cherries and plums in Wisconsin**, G. W. KEITT (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 112).—While engaged in a study of diseases of cherry and plum at Sturgeon Bay, Wis., the author found that the most serious leaf injury is due to *Cylindrosporium* spp.

A study was also made of *Coccomyces hiemalis* which causes leaf spot of sour cherry. This disease, it is claimed, was quite satisfactorily controlled on sour cherry trees which received their first application of spray when about three-fourths of the petals had fallen. Field observations indicate that early spring infections could be greatly reduced by plowing under or otherwise disposing of leaves about the bases of trees.

**The Surinam witch-broom disease of cacao**, J. B. RORER (*Bul. Dept. Agr. Trinidad and Tobago*, 15 (1916), No. 1, p. 5).—This is a discussion of the article by Stahel already noted (*E. S. R.*, 34, p. 847).

**Chestnut tree disease in Ardèche**, L. TRABUT (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 15, pp. 462, 463).—Reporting observations made in 1915 on the progress of the chestnut-tree disease in Ardèche, the author recommends the substitution of the cork oak, some varieties of which are resistant to cold, and of *Quercus ballota*, some varieties of which furnish edible acorns.

**The influence of the tannin content of the host plant on *Endothia parasitica* and related species**, M. T. COOK and G. W. WILSON (*New Jersey Stat. Bul.* 291 (1916), pp. 3-47).—A report is given of an investigation carried on cooperatively by the Bureau of Plant Industry of this Department and the New Jersey Experiment Station, in which the effect of tannin on the growth of the chestnut blight fungus (*E. parasitica*) and related species was studied. Commercial tannin preparations and some special extracts from chestnut bark were used in the experiments on cultures of *E. parasitica*, *E. radicalis*, and *E. radicalis mississippiensis* from different sources.

The results obtained with commercial tannin were not always comparable among themselves nor with those obtained when the specially prepared extracts were used. In almost every instance, without regard to the form of

tannin, a content of 0.8 per cent or more caused a retardation of germination, frequently followed by an abnormal stimulation of the growth of aerial mycelium. The species of *Endothia* and to some extent the strains of the same species showed considerable variations in their response to tannin. In the course of the investigations it was found that tannin was utilized by *E. parasitica*, the fungus being able to remove as much as 2 per cent from the substratum. The specially prepared extracts of pure tannin were either stimulating or only slightly toxic when combined with coloring matter or other substances associated with tannins.

**The chestnut blight and the white pine blight rust, A. B. BROOKS (W. Va. Dept. Agr. Bul. 12 (1915), pp. 21, figs. 9).**—This bulletin gives a general account of the chestnut disease due to *Endothia parasitica* and a very brief discussion of the blister rust of 5-leaved pines, the causal fungus of which has for its alternate host currant or gooseberry.

**Eelworm parasites of plants, P. FRANSEN (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 2, pp. 60-63, fig. 1).**—This is an address made before the State Fruit Growers' Convention, Palo Alto, Cal., 1915, giving the collected information and results of recent experience regarding nematodes. Particular reference is made to *Heterodera radicumicola*, which is increasing in importance in the Western States, about 500 species of plants, including the majority of truck garden crops, alfalfa, clovers, some grains, a number of fruit trees, and many weeds, now being known to be susceptible to this parasite.

The young nematodes, as a rule, enter through the tip of the rootlet, but they also pass into the young potato tubers through the lenticels, several entering frequently at the same point. They are distributed by such means as seed potatoes and transplanted seedlings, irrigation being one of the most important agencies. Soil thoroughly dried on tools or carried before the wind apparently does not convey infection. Eggs and larvæ are apparently completely destroyed in the stomach of animals fed upon infected plants. They resist freezing temperatures for a limited time only, the long, cold winters of the Northern States keeping them down in these localities. Character and consistency of soil are thought to play a part also in frost resistance. At least three months' time will be required to eradicate eelworms by flooding with water, but drying for a few minutes will kill eggs or larvæ, either on glass slides or on roots and tubers. There is also very little resistance to heat. In 23 hours, infested potatoes were free from live parasites, yet unimpaired as to germinability. It is thought probable that seed potatoes are safe after 24 hours' exposure to a temperature of 40° C. (104° F.). One per cent copper sulphate, acting for two days on the nematodes, had no effect. Formalin is also ineffective.

Remedies suggested include the use of uninfested soil and seed, summer fallowing of infested ground, deep plowing with consequent exposure of the soil to the sun's rays in hot, dry weather, and a system of rotation employing nonsusceptible crops, a number of which are mentioned. A marked infection is said to have been obtained in an experiment with corn and oats, which have been previously considered as immune.

**Injuries to plants kept in rooms, P. SORAUER (Ztschr. Pflanzenkrank., 25 (1915), No. 6, pp. 325-335).**—Observations on several house plants as detailed are considered to show that though injury from burning gas is theoretically possible, this cause is practically inoperative and is easily avoided entirely by ventilation. The injury which may be observed in case of several plants is probably due to the elevation of temperature and the drying of the atmosphere by the means employed to warm the air of the room.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Zoological record, D. SHARP** (*Zool. Rec.*, 51 (1914), pp. VI+[913]).—This continuation of the catalogue previously noted (*E. S. R.*, 33, p. 450) records the literature of 1914 and includes entries for earlier years that were received too late for inclusion in the previous volume.

**Game laws for 1916.**—A summary of the provisions relating to seasons, export, sale, limits, and licenses, T. S. PALMER, W. F. BANCROFT, and F. L. EARNSHAW (*U. S. Dept. Agr., Farmers' Bul.* 774 (1916), pp. 64, figs. 4).—This bulletin containing the seventeenth annual summary of the game laws of the United States and Canada has been prepared on the same general plan as those issued each year since 1902 (*E. S. R.*, 34, p. 157). It includes the proclamation of the President and the amended regulations for the protection of migratory birds, approved August 21, 1916, and the treaty with Great Britain for the protection of migratory birds in the United States and Canada, ratified August 29, 1916.

**Second annual report of bird counts in the United States, with discussion of results, W. W. COOKE** (*U. S. Dept. Agr. Bul.* 396 (1916), pp. 20, fig. 1).—A second count of the birds of the United States, here reported, is said to corroborate the general results obtained by the preliminary work of 1914, previously noted (*E. S. R.*, 32, p. 648).

The counts made in the Northeastern States during 1915 confirm those of the previous year and are said to indicate with reasonable assurance that one pair per acre is the average bird population in that part of the northeastern United States actually devoted to agriculture.

"An average of the returns of counts shows that, on farms where counts were made in that part of the Plains region east of the one-hundredth meridian and in the whole of the Southern States, for the part of the farm surrounding the farm home there is almost exactly the same density of bird population—for the former 125 and for the latter 131 pairs of nesting birds to each 100 acres—but the counts so far received do not furnish a sufficient basis for estimating the birds on the remainder of the farm. The data received tend to indicate that the western part of the Plains, the Rocky Mountain region, and the Pacific slope contain a smaller number of birds per acre than the Eastern States, but as yet no numerical statement may be attempted. . . .

"A bird population of 70 pairs of native birds of 31 species on 8 acres, at Olney, Ill.; 135 pairs of 24 species on 5 acres, at Wild Acres, Md.; 193 pairs of 62 species on 44 acres, at Indianapolis, Ind.; and 189 pairs of 40 species on 23 acres, at Chevy Chase, Md., a half acre of which showed 20 pairs of 14 different species; all indicate how largely birds will respond to food, shelter, and protection."

**A field ornithology of the birds of eastern North America, C. J. MAYNARD** (*West Newton, Mass.: Author, 1916. pp. 550, pl. 1, figs. 424*).—A popular handbook for field use.

**Common birds of southeastern United States in relation to agriculture, F. E. L. BEAL, W. L. MCATEE, and E. R. KALMBACH** (*U. S. Dept. Agr., Farmers' Bul.* 755 (1916), pp. 39, figs. 20).—This deals with the food habits and economic importance of 23 species of birds that commonly occur in the southeastern United States.

**How to attract birds in northwestern United States, W. L. MCATEE** (*U. S. Dept. Agr., Farmers' Bul.* 760 (1916), pp. 11, figs. 11).—This is the second of a series of publications (*E. S. R.*, 32, p. 347) in which the means of attracting and providing food supplies for wild birds about homesteads in the Northwestern States are especially described.

**Birds in their relations to man**, C. M. WEED and N. DEARBORN (*Philadelphia and London: J. B. Lippincott Co., 1916, 2. ed., rev., pp. VIII+390, pls. 18, figs. 103*).—A revised edition of the work previously noted (E. S. R., 15, p. 228).

**A new air-conditioning apparatus**, G. A. DEAN and R. K. NABOURS (*Kansas Sta. Rpt. 1915, pp. 46-54, figs. 4*).—Previously noted in part from another source (E. S. R., 33, p. 855).

**Effects of nicotin as an insecticide**, N. E. MCINDOO (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 3, pp. 89-121, pls. 3*).—The studies here reported in detail have been summarized by the author as follows:

"Nicotin spray solutions do not pass into the tracheæ, nor do they penetrate the integuments of insects. The fumes from nicotin used as a fumigant, the vapors from nicotin spray solutions, and the odoriferous particles from evaporated nicotin spray solutions or from powdered tobacco pass into the tracheæ and are widely distributed to all the tissues.

"Regardless of how it is applied, whenever nicotin kills insects, as well as all other animals, it kills by paralysis, which in insects travels along the ventral nerve cord from the abdomen to the brain. The writer does not know just how nicotin paralyzes the nervous system, but he does know that it prevents the nerve cells from functioning, and that in regard to the simplest animals its presence around the cells causes the same structural changes resulting in death as observed when other animals of the same kind are deprived of oxygen. In such cases it seems to kill physically rather than chemically, but the evidence presented does not conclusively prove this view. In the higher animals it may kill by interfering with oxidation in the cells; whether this is accomplished physically or chemically the writer does not know, but concluding from the properties of nicotin he is inclined to attribute more to its physical effects than to its chemical effects."

A bibliography of 25 titles is included.

**Insects injurious to alfalfa**, G. A. DEAN (*Kans. Agr. Col. Ext. Bul. 5 (1916), pp. 36, figs. 40*).—Summarized accounts are given of the more important insect enemies of alfalfa, including methods of control.

**Insects attacking onions**, H. A. BALLOU (*Agr. News [Barbados], 15 (1916), Nos. 366, p. 154, fig. 1; 367, pp. 170, 171*).—A brief account of the insect enemies of onions in the West Indies, of which the onion thrips ranks first in importance.

**The more important greenhouse insects**, H. B. WEISS (*New Jersey Stat. Bul. 296 (1916), pp. 3-42, figs. 33*).—This bulletin gives summarized accounts of the more important insect pests occurring in greenhouses, including control measures.

**The animal parasites of man**, H. B. FANTHAM, J. W. W. STEPHENS, and F. V. THEOBALD (*New York: William Wood & Co., 1916, pp. XXXII+900, figs. 423*).—This work is partly adapted from the fourth edition of Braun's *Die Tierischen Parasiten des Menschen*, the English or third edition of which has been noted (E. S. R., 17, p. 1011).

Following an account of parasites in general the protozoa are taken up in the first section (pp. 25-210) and in an appendix (pp. 733-752) by H. B. Fantham; the worms in the second section (pp. 211-482) and in an appendix (pp. 753-755) by J. W. W. Stephens; and the arthropods in the third section (pp. 483-616) by F. V. Theobald. A supplement containing clinical and therapeutical notes on the protozoa, worms, and arthropods (pp. 617-732); a bibliography (pp. 756-835); and an index (pp. 836-900) are also included.

**New Jersey's insects**, H. B. WEISS (*Sci. Mo., 3 (1916), No. 4, pp. 385-388*).—It is stated that of the insects listed from New Jersey, namely, 10,530, only 1.76 per cent are really destructive.

Reports of the government entomologist, 1915 and 1916, C. MASON (*Nyasaland Dept. Agr. Ann. Rpts. 1915, pp. 36-49; 1916, pp. 19-22*).—These reports record the occurrence of the more important insect pests of the years and the control measures applicable.

Some new entomogenous fungi in St. Vincent, W. NOWELL (*Agr. News [Barbados], 15 (1916), No. 363, p. 110*).—Reference is made to a new species of *Cordyceps* that attacks the larvæ of *Cryptorhynchus corticalis*, a species of *Isaria* on the larva of a root weevil, an undetermined fungus on the larvæ and adults of the cacao thrips (*Heliethrips rubrocincta*), and undetermined forms on the West Indian peach and purple scales.

The lesser migratory locust (*Melanoplus atlanis*), G. W. HERRICK and C. H. HADLEY, JR. (*New York Cornell Sta. Bul. 378 (1916), pp. 5-45, pls. 6, figs. 17*).—The lesser migratory locust, a native species widely distributed in the United States and Canada, has at times been a most destructive pest. In 1893 and 1894 it caused considerable injury to crops in the western counties of New York State, and during the past three years certain sandy sections of Clinton, Warren, Saratoga, Fulton, and to a less extent other counties, were subjected to an exceedingly severe outbreak. Rye, oats, and corn are said to have suffered the most, probably because they are the chief crops in the infested localities.

Oviposition commences about the middle of July and continues until cool weather sets in. The young nymphs, which hatch out in the spring, undergo five molts before reaching maturity in June, there normally being but one generation a year in New York State.

Control measures consist of fall and spring plowing of the breeding places to a depth of 6 or more inches, the use of the so-called Kansas poison bait, the hopperdozer, and spraying with arsenicals.

Brief notes are presented on related forms in New York, including the red-legged grasshopper (*M. femur-rubrum*), the two-striped grasshopper (*M. bivitatus*), the clear-winged locust (*Camnula pellucida*) the Carolina locust (*Disosteira carolina*), and the green-striped grasshopper (*Chortophaga viridifasciata*).

A bibliographical list of 34 titles is included.

The sugar-beet thrips, W. H. WHITE (*U. S. Dept. Agr. Bul. 421 (1916), pp. 12, pls. 2, figs. 8*).—A report of studies at Washington, D. C., of the sugar-beet thrips (*Heliethrips femoralis*), which is widely distributed in Europe and the United States, occurring principally in greenhouses. It has been taken out-of-doors on sugar beets and sugar cane and has a large number of food plants. At an average mean temperature of 73° F. the eggs required from 12 to 14 days for development and the four nymphal stages required 4, 8, 1, and 5 days, respectively. It was found that a spray, consisting of nicotin sulphate 6 oz., fish-oil soap 4 lbs., and water 50 gal., destroyed all the adults and 95 per cent of the nymphs.

Technical descriptions are given of its several stages and a bibliography of 18 titles is included.

The bedbug, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul. 754 (1916), pp. 12, figs. 4*).—This replaces the publication previously noted (*E. S. R., 14, p. 374*).

The chinch bug outbreak of 1910 to 1915, S. A. FORBES (*Illinois Sta. Circ. 189 (1916), pp. 3-59, figs. 13*).—This is a report of studies made during an outbreak of the chinch bug, the first beginnings of which were seen in Illinois in the fall of 1909 and continued with growing intensity and gradually widening area until the spring of 1915, when it collapsed.

"A careful computation of losses resulting, based upon a comparison of crop yields and crop conditions in 17 infested and 17 uninfested counties, shows

that the yield of corn, wheat, and oats in these infested counties was diminished by chinch bug infestation in the year 1914 as follows: Corn, \$5,015,874; wheat, \$1,356,039; oats, \$41,071—a total of \$6,442,984. . . .

"An analysis of the weather and other conditions for several years in the region where the chinch bug outbreak began, points to a conclusion that the immediate cause of its beginning was unusually hot midsummer weather, with no excessive rainfall, occurring in a region in which the food plants occupied a relatively large area, with winter wheat in especially large ratio. . . . The outbreak was brought to a conclusion in the spring and early summer of 1915 by heavy beating and flooding rains coming at times when the young bugs were hatching rapidly from the egg.

"The principal measures for the control of a chinch bug outbreak are the burning out of the insects in their winter quarters and their destruction at harvest time by means of impassable barriers and lines of post-hole traps placed beside infested fields of wheat. Although winter burning on a large scale proved impracticable in Illinois owing to wet and snowy winters, small scale field experiments with this operation, under conditions locally and temporarily favorable, destroyed from 50 to 75 per cent of the chinch bugs under the harborage burned over."

Experiments made with a view to finding a better material than coal tar for making barriers against the escape of chinch bugs at wheat harvest resulted in the selection of a petroleum product, a residue of distillation, containing 70 per cent of asphaltic materials and known as road oil No. 7. While a perfect substance for the purpose this material, however, has the disadvantage that it is not on the market and must be made solely for this special use. A farmer's chance experiment made in 1912 showed that crude creosote was almost as effective as coal tar or road oils, and it had the advantage that it could always be obtained without delay in any desired quantity from near-by sources of supply, and so was the substance principally used during the last year or two of the outbreak. Experiments showed that creosote differed from coal tar and the road oils in the cause of its effectiveness, the latter being impassable because they were thick and sticky, while the creosote repelled the insects by odorous vapors given off.

"Field experiments with practical operations, especially in 1910, 1911, and 1912, showed that an effective barrier could be made and maintained at an expense for labor and materials varying from \$1.50 to \$2 per day per mile, the difference depending mainly upon the character of the season."

The false chinch bug and measures for controlling it, F. B. MILLIKEN (*U. S. Dept. Agr., Farmers' Bul. 762 (1916), pp. 4, figs. 2*).—A severe outbreak of the false chinch bug (*Nysius cricæ [angustatus]*) during May and June, 1916, especially in Kansas and Colorado, led to the preparation of this information regarding control measures.

Are scales becoming resistant to fumigation? H. J. QUAYLE (*Univ. Cal. Jour. Agr., 3 (1916), No. 8, pp. 333, 334, 358*).—The author discusses fumigation experiments with fruit from different sections showing apparently that the red scale in the Corona district is more resistant than in Orange County.

Root louse control, D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1915, pp. 16-18*).—Experimental control work with the sugar beet root louse (*Pemphigus betæ*), accounts of which by Parker have been previously noted (*E. S. R., 33, p. 357*), was carried on in cooperation with the Montana Experiment Station.

Due to an unusually heavy rainfall in June and July the soil on all the plats was thoroughly moist most of the time during the migration period and

the amount of injurious infestation on all the plats was comparatively small. As a result tests made of several methods of irrigation failed to give conclusive results. It is believed, however, that the results obtained in 1914 and 1915 indicate that control by irrigation will be effective only in years when the precipitation is not above normal.

In tests of plats of land, three of which had been in oats the previous year and six in beets, the infestation of the beets which followed the oats was 70.3 per cent and the percentage injuriously infested 4.7, while of those which followed beets only 28.9 per cent were infested in any degree and only 0.73 per cent injuriously infested. These observations support the theory that the root louse usually does not hibernate in old beet fields.

The grape leaf-folder, J. F. STRAUSS (*U. S. Dept. Agr. Bul. 419 (1916), pp. 16, pls. 4, figs. 6*).—The author reports studies of the life history and habits of *Desmia funeralis* made in the vicinity of Washington, D. C., during the course of two years.

The injury which it causes, principally to the foliage of the grape, has frequently been described since 1885. The larvæ of the first brood have also been observed to eat the blossoms and young fruit. As soon as it is large enough the larva folds the leaf, exposing the undersurface, and within the protection of this fold skeletonizes the upper surface. Later in the season the skeletonized leaf dries up and exposes the fruit to the rays of the sun, which in case of a severe attack renders the fruit unmerchable.

The pest occurs in all regions of the United States where wild or cultivated grapes grow, and extends into a considerable portion of Canada, but it has not as yet, with occasional exceptions, assumed the proportions of a pest of much economic importance outside of the Central States between the latitudes of 35 and 40°. It has been collected on the fox grape (*Vitis labrusca*), southern fox grape (*V. rotundifolia*), *V. cordifolia*, the Virginia creeper (*Parthenocissus quinquefolia*), and two varieties of redbud (*Cercis canadensis* and *C. chinensis*).

At Washington, D. C., the greatest number of moths issued during the early part of May, but adults have been obtained the latter part of April, through May, and most of June. The eggs are usually deposited singly on the underside of the leaf, along the midrib or other veins, or in the angles formed by the branching of the veins, and have also been found scattered over the grape canes. The eggs hatch in from 8 to 10 days. The larva, which molts six times, feeds almost continuously during the first three or four days between molts, being especially active at night. In the latitude of Washington, there are two generations each year. The majority of the first brood larvæ pupate during July, the average length of time passed in the larval stage being about 4 weeks. The larvæ of the second brood begin to pupate in September and by the middle of October few, if any, are to be found in the leaves in the latitude of Washington. The full-grown larvæ leave their shelters and drop to the ground, where they transform among fallen leaves, trash, etc., and in the case of the second brood, pass the winter as pupæ.

Seven hymenopterous and 3 dipterous parasites are recorded as having been reared by the author from the grape leaf-folder, of which notes are given on *Apanteles canarsia*, *Meteorus dimidiatus*, *Pardianlomella ibseni*, *Habrobracon johannseni*, and *Exorista pyste*.

As regards control measures it is stated that vineyards regularly sprayed with arsenicals for the control of the grape rootworm, grape-berry moth, etc., will be practically free from injury by the grape leaf-folder. Where it has been troublesome in previous years, it is recommended that the vines be

sprayed with arsenate of lead at the rate of 2 lbs. of the paste or 1 lb. of the powdered article to 50 gal. of water, shortly after the blossoms have fallen.

A bibliography of 26 titles is included.

*Tinea cloacella* as a mushroom pest, A. KRAUSSE (*Ztschr. Forst u. Jagdw.*, 48 (1916), No. 2, pp. 73-78, figs. 12).—This reports morphological and biological studies of *T. cloacella*, which was found to develop in an edible mushroom, *Boletus edulis*.

Experiments during 1915 in the destruction of fly larvæ in horse manure, F. C. COOK and R. H. HUTCHISON (*U. S. Dept. Agr. Bul.* 408 (1916), pp. 20).—This bulletin reports the results of investigations carried on during 1915 in continuation of those of 1913 and 1914, previously noted (*E. S. R.*, 33, p. 455). During the fly season the larvicidal action of infusions of 18 plant materials was tested, none of which, with the exception of hellebore, was sufficiently economical and effective to be classed as a practical larvicide.

Summarizing the results of the three seasons' work, it is stated that borax, used at the rate of  $\frac{3}{4}$  lb. to 10 gal. of water and sprinkled over 8 bu. of manure, is the least expensive and the most effective larvicide. It is pointed out that caution should be used, however, in treating manure to be used for agricultural purposes because of the injurious action on plant growth of excessive applications of borax. Powdered hellebore, used at the rate of 0.5 lb. to 10 gal. of water on 8 bu. of manure, is an effective larvicide and without action on plant growth. The indications are that calcium cyanamid, acid phosphate, and kainit mixtures can be used as effective larvicides if 0.5 lb. of calcium cyanamid is present in the mixture per bushel of manure treated.

The response of the house fly (*Musca domestica*) to ammonia and other substances, C. H. RICHARDSON (*New Jersey Stat. Bul.* 292 (1916), pp. 3-19).—The studies here reported, preliminary accounts of which have been previously noted (*E. S. R.*, 34, p. 160; 35, p. 466), have led to the following conclusions:

House flies are attracted to fermenting organic substances largely by the odor of ammonia, a product of this fermentation. Ammonia attracts a preponderance of females. Flies can be induced to oviposit upon certain substances near which ammonia is volatilized. Flies lay their eggs by preference in organic substances which are capable of furnishing food for their larvæ and they have some power which enables them to detect such substances. Butyric and valerianic acids augment the oviposition response of the house fly to ammoniated cotton.

Flies and their relation to epidemic diarrhea and dysentery in Poona, J. MORISON and W. D. KEYWORTH (*Indian Jour. Med. Research*, 3 (1916), No. 4, pp. 619-627, figs. 3).—"The evidence indicates that flies, in spite of their number, do not contribute appreciably, if at all, to the mortality in the native city of Poona, or to the annual epidemic of gastro-intestinal disease in Poona cantonment."

[Report of the] department of entomology, H. T. FERNALD (*Massachusetts Sta. Rpt.* 1915, pt. 1, pp. 65a-68a).—This brief report of the work of the year deals particularly with the strawberry crown girdler (*Otiorrhynchus ovatus*), which in the spring of 1915 appeared in enormous numbers in a forest nursery and caused an estimated loss of over \$15,000. Examinations made of beds of 2-year-old white pines, the tops of which were turning brown, showed that the larvæ had girdled the stems and roots at from 1 to 3 in. below the surface of the ground. In addition to white pine, the red pine, Scotch pine, *Juniperus virginiana*, blue, Douglas, and Norway spruce, and even sugar maple seedlings of the 2-leaf age were attacked, and in many cases severely injured. When first examined, on May 15, the larvæ were nearly mature and most of them pupated within two weeks thereafter. The beetles were appearing by the mid-

dle of June and were at their maximum abundance about July 7. The evidence would indicate that in this infestation at least some portion of the larval feeding took place in the fall and was resumed in the spring, and that the adult period of life extended over several months.

Examinations of beds that had been stripped of plants and cultivated every two or three days as recommended showed numerous dead pupæ, but indicated that some larvæ at least pupated lower than a harrow would reach. This led to the recommendation that plowing be done once or twice in order to reach the more deeply-placed pupæ. Later when the beetles emerged trapping methods were resorted to with considerable success, weed piles placed between the beds having proved more effective than the use of boards or burlap. The use of repellants was recommended and it is advised that beds cleared of plants be not reset until the adult beetles disappear.

**The soy bean stem borer**, H. L. DUTT (*Agr. Jour. Bihar and Orissa [India]*, 3 (1915), No. 1, pp. 52-56, figs. 3).—With the introduction of the soy bean on an experimental scale at Sabour a cerambycid beetle of the genus *Nupserha* has appeared and become a source of serious damage. An account is given of its life history and habits, together with recommendations as to the prevention of injury, and remedial measures.

**Rhynchophora or weevils of northeastern America**, W. S. BLATCHLEY and C. W. LENG (*Indianapolis: The Nature Publishing Co., 1916, pp. 682, figs. 155*).—This volume, following the plan adopted in the senior author's *Coleoptera or Beetles of Indiana* (E. S. R., 24, p. 259), furnishes keys to the families, subfamilies, tribes, genera, and species of *Rhynchophora*. A total of 1,084 species are described as occurring in the United States and Canada, east of the Mississippi River. The description of each species is followed by notes on its distribution, food, habits, etc., so far as known. The classification used is mainly that of LeConte and Horn, modified where necessary by recent studies.

A bibliography of the principal works to which reference has been made in the text, and an index to the plants mentioned, to the families, subfamilies, tribes, and genera, and to the new genera, species, and varieties, are included.

**The cottonwood borer**, F. B. MILLIKEN (*U. S. Dept. Agr. Bul. 424 (1916), pp. 7, pl. 1, figs. 3*).—This is a report of studies of *Plectrodera scalator* in cottonwood (*Populus deltoides*) and willow (*Salix alba*) made at Garden City, Kans., in 1913.

The eggs are deposited in the trunks of cottonwoods at or a little below the surface of the ground, principally during July and August. The young larvæ cut the bark and prevent the sap flow and the large larvæ tunnel the wood, thus weakening the resistance of the trees to the wind. The adults emerge from about the middle of June to the first of August of the second summer following emergence from the eggs.

It is pointed out that oviposition in shade trees may be prevented by screening the bases and directions are given for the preparation of such screens. "The young larvæ can be removed before they injure the trees severely if the remedial work is done during the first two weeks of September, but removal of the large larvæ from deep tunnels often injures the trees more than would the larvæ if allowed to remain and complete their development."

**The southern corn billbug**, Z. P. METCALF (*N. C. Agr. Ext. Serv. Circ. 19 (1916), pp. 21, figs. 13*).—This is a summarized account of a pest that is a very destructive enemy of corn in the eastern part of North Carolina. Reports of studies made of this insect by Smith in North Carolina (E. S. R., 29, p. 56), Kelly in southern Kansas and northern Oklahoma (E. S. R., 25, p. 159), and Hayes in southern Kansas (E. S. R., 35, p. 760) have been previously noted.

The banana weevil, H. A. BALLOU (*Agr. News [Barbados], 15 (1916), No. 364, p. 123*).—It is reported that the banana weevil (*Sphenophorus [Cosmopolites] sordidus*) has appeared in some numbers in certain districts of Jamaica.

Productive beekeeping, F. C. PELLETT (*Philadelphia and London: J. B. Lipincott Co., 1916, pp. XIV+302, pl. 1, figs. 134*).—In this volume the state apiarist of Iowa considers modern methods of production and marketing of honey.

Bees and how to keep them, F. W. L. SLADEN (*Canada Expt. Farms Bul. 26, 2. ser. (1916), pp. 56, pls. 4, figs. 34*).—This replaces the bulletin previously noted (E. S. R., 27, p. 662).

Fifteenth annual report of the Illinois State Beekeepers' Association, compiled by J. A. STONE (*Ann. Rpt. Ill. Beekeepers' Assoc., 15 (1915), pp. 177, pl. 1, figs. 9*).—This report (E. S. R., 35, p. 467) includes a paper on Outdoor Wintering (pp. 51-58), by E. F. Phillips.

Rocky Mountain spotted fever.—A report of laboratory investigations of the virus, L. D. FRICKS (*Pub. Health Rpts. [U. S.], 31 (1916), No. 9, pp. 516-521, fig. 1*).—A report of studies of the causative organism of the disease, which is transmitted by *Dermacentor venustus*.

## FOODS—HUMAN NUTRITION.

The nutritive properties of corn, A. G. HOGAN (*Jour. Biol. Chem., 27 (1916), No. 1, pp. 193-208*).—Feeding experiments with laboratory animals (rats) are reported in an attempt to determine the nature of the deficiency of an exclusive diet of maize. The problems studied include the adequacy of the inorganic constituents, the adequacy of maize proteins, and the presence of growth accessories. The results of the work are summarized by the author as follows:

"The evidence indicates that when corn is fed to rats as the sole dietary the mineral constituents are the first limiting factor, and then the protein. In the case of swine these findings are apparently reversed. Protein is here the first limiting factor, and then the mineral element. The data also indicate that the corn proteins are less efficient for growth than casein. The addition of lysin and tryptophane to maize did not increase its efficiency for growth. The addition of some of the adequate proteins (egg white) seemed of only slight benefit. In view of these facts it seems possible that one of the limiting factors in corn as a food for growing rats is one or more of the growth accessories.

"Young rats on a corn diet grow more rapidly when the grain is supplemented with casein than when supplemented with egg white. This observation assumes added significance since food mixtures containing protein-free milk, butter, and egg white are more efficient for growth than mixtures of corn and egg white, even though the protein of the corn mixture furnishes a relatively higher percentage of calories than does the protein of the more efficient diet.

"Autoclaved corn mixtures failed to maintain body weight, and ultimate failure resulted.

"Since swine grow rapidly on a mixture of corn and egg white, it is believed that corn contains sufficient of the growth accessories for normal growth in swine."

The nutritive value of yeast, polished rice, and white bread, as determined by experiments on man, C. FUNK, W. G. LYLE, D. McCASKEY ET AL. (*Jour. Biol. Chem., 27 (1916), No 1, pp. 173-191*).—In the investigation here reported four normal men were given a diet of yeast, white rice, and bread.

It was found in the experiments where yeast was taken for nearly two weeks that it was insufficiently utilized, the nitrogen content of the feces being high, and in some instances undigested yeast was detected in the feces. The authors state that yeast, on account of its high purin content, "causes a distinct rise of uric acid in the blood, and for this reason can not be used to the exclusion of all other food."

The experiments with vitamin-free food, in the form of white rice and white bread, confirmed the results of other investigators who found that to obtain the positive nitrogen balance more white bread is required than whole wheat bread or potatoes. This positive balance occurred in spite of the low nitrogen content of the feces and indicated good resorption. The experiments were not of sufficient duration to determine whether the low value of the vitamin-free food was due solely to the absence of vitamins.

As a result of the investigations the authors conclude as follows:

"Yeast can not very well be recommended as a sole protein source, as a large part of the yeast nitrogen apparently has no food value. It is badly assimilated and occasions a rise of uric acid figures in the blood. The amount of nitrogen which would be fully adequate in the form of potatoes was proved to be insufficient with yeast. This also applies to . . . [the] experiment with white bread and white rice. . . . [The authors] were unable in . . . [their] experiment to get a positive nitrogen balance by the addition of vitamin."

In the authors' opinion the investigation does not warrant the verdict that yeast possesses no value in dietetics. There are a number of complex factors which must be taken into consideration, such as problems of personal idiosyncrasy as to the taste and methods of administration of the yeast and questions of amino acid synthesis after the yeast protein and purin bases have entered the organism. There is need of further research to determine how far anaerobic yeast can be made of any supplementary metabolism value when consumed in conjunction with other foods to remedy dietetic deficiencies.

**Rye flour and rye bread**, E. BRAUN (*Northwest. Miller*, 108 (1916), No. 8, pp. 513, 514, figs. 7).—The author discusses the difference in treatments necessary for rye and wheat flour sponge, and describes methods for making Russian black bread, German black bread, Pomeranian barley bread ("gerstel brot"), and pumpernickel.

**Some tests of flour made from Egyptian wheats**, F. HUGGES (*Min. Agr. Egypt, Tech. and Sci. Serv. Bul.* 10 (1916), pp. 1-9, figs. 5).—The "strength" of various Egyptian wheats was estimated by noting the size of the loaf as determined by the measurement of the gas evolved on fermenting flours with yeast.

The strength and nitrogen content of Indian wheat was found practically the same whether grown in India or Egypt. Red grains seemed to have a greater strength and greater nitrogen content than white grains, perhaps due to the time of harvesting. The addition of mineral manures to the soil increased the amount of fermentable material by nearly 30 per cent, although the nitrogen content remained practically unchanged. No actual baking experiments were made.

**[Inspection of shellfish]** (*Maine Sta. Off. Insp.*, 78 (1916), pp. 41-52).—Data are given regarding the examination of samples of clams, scallops, and oysters, purchased in the fall and winter of 1915 and 1916. The effect upon the nutritive value of soaking or floating shellfish in fresh water is discussed, standards are given regarding the sale of shellfish, and a statement as to administration made by A. M. G. Soule.

**Studies on growth.—III, The comparative value of lard and butter fat in growth,** C. FUNK and A. B. MACALLUM (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 51-62, figs. 2).—The experiments reported in this paper were carried out to determine the relative value of lard and butter fat as the fat fraction of the artificial diets studied in previous work in this series (E. S. R., 34, p. 561).

If laboratory animals (rats) were maintained on a diet containing dried, powdered yeast and lard as the fat component, they grew normally for from 60 to 90 days but eventually displayed scorbutic symptoms. This condition terminated fatally if the diet was not changed. By substituting moist yeast or autolyzed yeast for the dried preparation the rats could be maintained upon the diet for a longer period. Similar results were obtained by adding to the drinking water orange juice (which has neither growth-promoting nor maintaining properties unless supplemented by yeast).

The diets in which butter partially or wholly replaced lard had a slight superiority over those containing lard alone. This superiority was more than could be explained by the antiscorbutic properties of the butter. Even in this case the existing deficiencies were not entirely corrected, since many rats declined on the diet. Rats which failed on lard did not always recover on a diet containing butter.

It appeared possible also that yeast, on account of its high content in purins, and perhaps other constituents, was not an ideal addition to the diet in experiments of long duration, even in spite of its marked growth-promoting power. "The impaired nutritive value of heated casein does not seem to be due to destruction of amino acids but to destruction of vitamins."

**Studies on growth.—IV, The action of yeast fractions on the growth of rats,** C. FUNK and A. B. MACALLUM (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 63-70, figs. 2).—Attempts were made to separate out a physiologically active fraction from yeast, which would stimulate the growth of young laboratory animals (rats). This was suggested by the close relationship existing between the beri-beri and growth problems. The authors state that the same experimental difficulties encountered in the investigation of the beri-beri vitamin were encountered in this study, and that the problems of neither beri-beri nor growth will be solved until more adequate methods for the isolation of the vitamin are available.

"The fractionation of yeast with phosphotungstic acid shows that the growth-promoting substance is carried down with the precipitate, and a large part of its activity is lost during the fractionation."

**The isolation of a growth-producing substance from sheep pancreas,** W. H. EDDY (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 113-126, figs. 9).—In attempting to establish the presence of a vitamin in the water-soluble portion of the alcoholic extract of sheep pancreas, feeding experiments were made with laboratory animals (rats). The following solutions were used: A filtered water-soluble portion of the alcoholic extract of pancreas; Lloyd's reagent after shaking with the water-soluble portion of the alcoholic extract; the filtrate from the water-soluble portion after treatment with Lloyd's reagent; and the phosphotungstic precipitate of the water-soluble portion after the removal of phosphotungstic acid with amyl alcohol.

The results of these experiments seemed to prove that the water-soluble portion of the alcoholic extract of pancreas contains a substance capable of inducing marked increase in growth. This substance, which is neither a protein nor a fatty substance, is removed from the extract without loss of power by treatment with Lloyd's reagent, and is also precipitated by phosphotungstic acid. Amino nitrogen determinations made on the different solutions used

indicated that the growth stimulation is something other than amino-acid stimulus.

The study of certain dietary conditions bearing on the problem of growth in rats, C. FUNK and J. POKLOP (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 1-14, figs. 4).—This paper presents data obtained in observation of several hundred laboratory animals (rats), regarding the influence exerted by various substances, which bring about a better condition of the laboratory animals not only from the standpoint of nutrition but from the standpoint of correcting deficiencies in diet. The results obtained are summarized as follows:

“By an addition of milk or yeast to the normal diet, the growth of rats can be accelerated. Oats in dry state or subjected to germination proved to be an inadequate diet for young rats. Yeast can not substitute the casein in the diet and this very likely because of its toxic properties. Young rats grow less when milk instead of yeast is used in the diet, and they do not grow at all on orange juice as addition. Using Lloyd's reagent for precipitation of the growth-promoting substance from autolyzed yeast, it was found that by this process the separation seems to be not complete; furthermore, the yeast loses some of its original value as a stimulant to growth.”

Dietetic deficiency, H. H. GREEN (*So. African Jour. Sci.*, 12 (1916), No. 8, pp. 289-308).—A summary and digest of data regarding the relation of so-called vitamins to the following deficiency diseases: Beri-beri, scurvy, pellagra, rickets, and osteomalacia, and lamziekte and other deficiency diseases of cattle.

Studies in creatin metabolism.—I-IV, F. P. UNDERHILL and E. J. BAUMANN (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 127-139, 141-146, 147-150, 151-160).—Four papers are presented.

I. *Possible interrelations between acidosis and creatin elimination.*—In the experiments here reported laboratory animals (rabbits) were fed upon diets containing an adequate carbohydrate supply, but of such a nature that one diet would yield ash of pronounced acidity, another a distinctly basic ash, and a third type of diet consisting of a mixture of the two. The acid-producing foods were whole oats and cracked corn, and the base-producing food was fresh carrots.

It was found that upon a diet of oats and corn furnishing an adequate supply of carbohydrate creatin appeared promptly in the urine of the animal. This phenomenon was associated with marked acidosis as measured by the hydrogen ion concentration of the urine. Oats and corn were found to be pronounced acid-producing foods, but if a base-producing food, such as carrots, was fed to rabbits with creatinuria this symptom disappeared, as the urine became alkaline.

“The protein per se is without special significance in the phenomenon under discussion; for upon a diet consisting of oats, corn, and carrots creatin fails to appear in the urine, and the reaction of the latter remains alkaline. Equally significant is the further fact that the ingestion of hydrochloric acid with the mixed diet causes the appearance in the urine of significant quantities of creatin. Simultaneously, the hydrogen ion concentration of the urine is markedly increased.

“The conclusion seems justified that there is an interrelationship between acidosis and creatin elimination. Creatin in the urine may prove to be an index of a condition of acidosis in the organism.”

II. *The influence of alkali upon creatin elimination during inanition.*—Data are reported regarding the influence of starvation upon the hydrogen ion concentration in the urine of laboratory animals (rabbits), and also the influence

of the administration of alkali upon creatin elimination during inanition. The results of the experiments are summarized as follows:

"Administration of alkali during the earlier days of starvation may greatly diminish or completely abolish the creatinuria of that condition. Later in the period of inanition introduction of alkali may not show as marked an influence upon the existing creatinuria. The results of these experiments lend support to the hypothesis that there exists a relationship between acidosis and creatin elimination."

III. *The influence of alkali upon the creatinuria of phlorizin glycosuria.*—The effect was studied of the administration of relatively large quantities of sodium bicarbonate upon the creatinuria in the case of phlorizinized dogs. The results obtained showed that "the administration of relatively large quantities of sodium bicarbonate is without appreciable influence upon the elimination of creatin during phlorizin glycosuria." This is true whether or not the animal is in a state of complete phlorizination. The authors conclude that more than one factor may govern the mechanism leading to creatinuria.

IV. *The relationship of creatinuria to carbohydrate metabolism and acidosis.*—The experiments reported in this paper were for the purpose of determining whether creatin may be excreted in the urine, under circumstances where carbohydrate depletion prevails, without an accompanying acidosis. A study was made of the creatinuria induced by hydrazin in the case of the dog as an example of such carbohydrate deficiency. The results of the experiments are summarized as follows:

"The subcutaneous administration of hydrazin to dogs induces a marked creatinuria which in general closely parallels the period of hypoglycemia provoked. These observations corroborate the results of previous investigations.

"During the period of hypoglycemia and most marked creatinuria the hydrogen ion concentration of the urine is greatly depressed—even to the point of marked alkalinity. The alkalinity is probably due to the presence of carbonates.

"The relationship of hypoglycemia and alkalosis again emphasizes the significance of acid-base equilibrium in the regulation of the blood sugar content.

"The results here presented make it evident that creatin elimination in the urine may be induced by at least two different sets of conditions: (1) Creatin may appear in the urine in states of acidosis where carbohydrate deficiency is not involved, and (2) creatinuria may be present during carbohydrate deficiency even in the absence of acidosis."

Alterations in the output of certain urinary constituents as determined by changes in the character of the diet, F. P. UNDERHILL and L. J. BOGERT (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 161-168).—In view of the facts noted in the above investigation—that changes in the character of the diet may result in the appearance or the disappearance of creatin in the urine—experiments were carried out to determine whether these changes in the diet would result in changes in the output of other urinary constituents, consideration being given to the differences in intake of various components of the diet.

It was found that "upon a diet of corn and oats the output of phosphorus in the urine of rabbits is far in excess of the intake of this element in the food. Since the hydrogen ion concentration of the urine is very high under these circumstances, the great excess of phosphoric acid in the urine may be regarded as a method of regulating acid-base equilibrium in the body of the rabbit.

"Ammonia excretion is variable under changing conditions of diet, and although it appears that this base may function as a neutralizing agent at

times further experiments are necessary before the laws of ammonia excretion in the rabbit can be formulated. Calcium elimination is too variable to justify inferences being drawn under the experimental conditions.

"The results obtained indicate that the creatinuria observed upon a grain diet can not be explained upon the hypothesis of food insufficiency."

**The volume of urine in young healthy adults on a constant diet,** T. ADDIS and C. K. WATANABE (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 267-272).—In connection with the above investigation a large amount of data was obtained regarding the volume of urine of subjects on a constant water intake, which are summarized as follows:

"The volume of urine in normal individuals on a constant diet with the same water intake is extremely variable for any single day or part of a day. The average volume of the last three days of the diet, when the water intake was 2,070 cc. varied in 20 individuals from 1,013 to 1,712 cc. for a 24-hour period, from 684 to 1,195 cc. for the first 12 hours of the day, and from 501 to 788 cc. for the first 8 hours of the day. The percentage of the 24-hour volume excreted during the 12 hours of the night did not exceed 47 per cent in any subject. . . .

"An increase of 1,000 cc. a day in the water intake more than doubled the volume of urine but did not appreciably increase the rate of urea excretion.

"An increase in the rate of urea excretion induced by the ingestion of urea, the water intake remaining constant, was accompanied by a considerable increase in the volume of urine."

**The rate of urea excretion.—I, A criticism of Ambard and Weill's laws of urea excretion,** T. ADDIS and C. K. WATANABE (*Jour. Biol. Chem.*, 24 (1916), No. 3, pp. 203-220).—From a study of the relationship between the concentration of urea in the blood and the rate of urea excretion, when the concentration of urea in the urine is the same, and the relationship between the concentration of urea in the urine and the rate of urea excretion, when the concentration of urea in the blood is the same, the authors concluded as follows:

"The rate of urea excretion in man varies under physiological conditions in a manner which can not be explained by the concentrations of urea in the blood and urine. There is a tendency for an increased rate of urea excretion to exist with higher blood urea concentration in cases in which the urine concentration is the same, and for an increased rate of urea excretion to be accompanied by a lowering of the urea concentration in the urine in cases in which the blood concentration is the same. This relationship, however, is one which is frequently obscured, even in individuals under the same conditions as regards nitrogen and water intake. Other factors than urea concentration are important in determining the rate of urea excretion by the normal kidney."

**The rate of urea excretion.—II, The rate of excretion of administered urea in young healthy adults on a constant diet,** T. ADDIS and C. K. WATANABE (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 249-266).—A study was made of the rate of excretion of urea administered to young, healthy adults who were on a constant diet, the aim being to obtain detailed information regarding the range of variation in the function of a normal kidney under normal conditions.

In 39 experiments no evidence of variability in kidney action was obtained in the work of excreting performed urea added to a constant diet. From this it is concluded that a normal kidney under constant conditions possesses a high degree of constancy of function.

"The rate of excretion of the administered urea during successive periods of the 24 hours showed that the repetition of large doses of urea did not elicit the condition which has been described as 'kidney fatigue.'

A fraction of the urea which was administered remained in the body after 24 hours. This urea was not retained because of any failure on the part of the kidneys to eliminate it, for the amount retained was no larger when 40 than when 20 gm. of urea were taken."

**The interrelations of blood fat and blood sugar content of dogs under the influence of hydrazin,** F. P. UNDERHILL and E. J. BAUMANN (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 169-172).—The object of this investigation was to determine the relation of the fat content to the sugar content of the blood in the case of laboratory animals (dogs) under the influence of hydrazin, which results in a low blood sugar content and the loss of glycogen from both the liver and muscles, and induces a so-called "fatty" liver.

The experiments showed that during the first days of fasting there was a tendency for the blood fat to decrease. This period was followed by one in which there was an increase of fat content up to approximately the initial value. During the interval of inanition studied there appeared to be little or no relation between the blood fat and blood sugar content.

"In hydrazin poisoning blood fat is markedly increased, the maximum being coincident with the condition of hypoglycemia characteristic of hydrazin. Blood fat returns to the fasting value as the sugar of the blood regains the normal."

**The toxicity of carotin,** H. G. WELLS and O. F. HEDENBURG (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 213-216).—The authors describe the method of preparation from fresh carrots of the pigment carotin used in the experiments reported, in which the toxicity of carotin was determined in the case of laboratory animals (guinea pigs) given intraperitoneal and intradermic injections of the substance dissolved in olive oil. The doses of carotin injected were much larger than the amounts which can be obtained from any food, the larger doses being as much as that contained in 200 kg. of flour.

"These experiments indicate that even in relatively very large doses carotin, whether in its natural state or saturated with chlorin, is almost entirely devoid of toxicity. Such large amounts as 20 mg. injected intradermically cause only a local edema and inflammation, but no necrosis."

**Clinical calorimetry.—XVIII, The number of places of significant figures in the data of metabolism experiments,** F. C. GEPHART, E. F. DUBOIS, and G. LUSK (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 217-223).—Three factors are discussed as influencing the number of places of significant figures in the data. These are the accuracy of the analytical results, the possible errors in the methods of calculation, and the significance of the findings. It is concluded that the analytical error in metabolism work is seldom much less than 1 per cent and that a variation of 1 per cent in the results of an experiment would not change its significance or affect its interpretation.

"For these reasons, it seems unnecessary to publish more than three significant figures in the tables of data and in some cases it is not worth while to publish more than two. In order to avoid the accumulated rejection error it is advisable to retain four figures wherever possible in the calculations and reject the fourth digit only in the final result."

A table is given showing the number of places of significant figures adopted as standards in the publication of metabolism data.

For earlier work in this series see E. S. R., 35, p. 369.

## ANIMAL PRODUCTION.

**Meat situation in the United States.—V, Methods and cost of marketing live stock and meats,** L. D. HALL, F. M. SIMPSON, and S. W. DOTY (*U. S. Dept. Agr. Rpt. 113 (1916), pp. 98, pls. 20*).—In this fifth report of this series (E. S.

R., 35, p. 666) only those phases of the marketing of live stock and meats which bear most directly upon the economic aspects of the meat situation are considered. The report sets forth the results of studies recently conducted by the Office of Markets and Rural Organization, supplemented by data from other sources.

The objects in view in the investigations were to define and differentiate the principal methods by which live stock is marketed in the United States; to show the present relative importance of the several methods in the country at large and in the different States and agricultural regions; to analyze the more prominent items of cost involved in the various stages of the marketing of live stock and distribution of meats, with special reference to the reduction of cost through improvements in marketing methods and facilities; and to compare the margins or relative returns realized by each of the important classes of interests that participate in the movement of meat products from producers to consumers. The kinds of meat animals considered in the report are cattle, hogs, and sheep.

"Three general methods of marketing are open to producers of meat animals: First, through the large public stockyards and packing centers; second, by means of local butchers and packers; and third, in the form of farm-prepared meats. . . . Estimates show that about one-half of the beef cattle, two-thirds of the hogs, and four-fifths of the sheep and lambs marketed pass through the large central markets; one-third of the beef cattle, one-twelfth of the hogs, and one-eighth of the sheep and lambs are sold for local slaughter; one-tenth of the beef cattle, one-third of the hogs, and one-twentieth of the sheep and lambs are slaughtered on farms and ranges. . . .

"In the United States relatively more sheep are shipped in carload lots by owners than any other class of live stock; cattle follow second, hogs third, and calves fourth. More hogs are marketed by local dealer-shippers than other classes of live stock, and calves, cattle, and sheep follow in the order named. . . .

"Cooperative live-stock shipping associations bring greater net returns to the farmer because of the reduction of marketing expenses and the realization of actual market prices. These associations also have educational features which are of importance to any community having live stock to market in small lots. . . .

"Direct marketing will remain an important factor in those parts of the country remote from centralized markets. . . .

"Average freight rates on live stock for the years 1911-1913 were 10 cts. per hundredweight for eastern or official territory, 11.9 cts. for southern territory, and 14.9 cts. for western territory. Replies to inquiries show that train service is satisfactory in a majority of cases. The total claims for live stock loss and damage in transit on 27 railroads amounted to \$1,245,477.81 during the fiscal year 1913-14. . . .

"The largest single factor in the marketing of meat animals in the United States is the system of centralized live-stock markets. These markets not only are a medium through which live stock is sold for slaughter, but a large proportion of stocker and feeder cattle also passes through them. The terminal charge at most centralized markets is \$2 per car. Yardage is 25 cts. a head on cattle, 10 cts. on calves, 8 cts. on hogs, and 5 cts. on sheep at a majority of the markets. Commission charges are 60 cts. per head on cattle, 25 cts. on calves, 20 cts. on hogs, and 10 cts. on sheep at most markets.

"Wholesale slaughtering and meat packing constitute the chief outlet for market stock suitable for slaughter. The most extensive development of meat

packing is found at Chicago and Missouri River points. . . . Public abattoirs have been established in 22 cities in 13 States. Seven of these establishments are owned and operated by the city, while the remaining 15 are owned privately and operated under city inspection. Local packing houses are distributed mainly in the more important live-stock producing States and in sections remote from live-stock markets and packing-house centers. Cooperative packing houses recently have been promoted in a number of communities in six States. . . .

"The marketing of farm-prepared meats, although comparatively limited in relation to the industry as a whole, is practiced more or less in almost all parts of the country. The curing of meat at ice plants is a recent development in local marketing in the South. . . . The parcel-post method of marketing meat is limited in comparison with the other methods, yet the amount thus marketed is considerable as a sum total.

"The correlation between average live-stock and meat prices is closer than generally is understood. Daily fluctuations in live-stock quotations frequently are large and abrupt and constitute one of the most adverse features of live-stock market conditions. Meat prices from day to day tend to follow general averages of previous years more closely. The results of investigations of the marketing of 9 lots of cattle through centralized markets show that from 54 to 85 per cent of the gross returns was received by the stockmen, from 2 to 5 per cent was absorbed by marketing expenses, 2 to 9 per cent was received gross by packers, and 8 to 33 per cent by retailers. The retailers' gross margin, as shown from the results of marketing locally five shipments of cattle, varied from 15 to 38 per cent of the gross returns. From 62 to 84 per cent of the gross returns on these cattle was received by the owner."

**The marketing of live stock**, D. A. GAUMNITZ (*South St. Paul, Minn.: W. M. Campbell Commission Co., 1916, pp. 42*).—This treats of methods of marketing live stock, preparing animals for shipment, loading, feeding in transit, and other related topics.

**On the general theory of multiple contingency with special reference to partial contingency**, K. PEARSON (*Biometrika, 11 (1916), No. 3, pp. 145-158*).—A mathematical discussion of the theories of multiple and partial contingency, in which a large number of formulas are set forth.

**On certain probable errors and correlation coefficients of multiple frequency distributions with skew regression**, L. ISSERLIS (*Biometrika, 11 (1916), No. 3, pp. 185-190*).—Formulas are given for use in the systematic investigation of statistical constants of multiple correlation and of their probable errors in cases in which skew regression is involved.

**On the probable error of a coefficient of contingency without approximation**, A. W. YOUNG and K. PEARSON (*Biometrika, 11 (1916), No. 3, pp. 215-230*).—In this paper the authors consider the variation of  $\phi^2$  on the hypothesis of Pearson<sup>1</sup> but without approximation.

**On some novel properties of partial and multiple correlation coefficients in a universe of manifold characteristics**, K. PEARSON (*Biometrika, 11 (1916), No. 3, pp. 231-238*).—The object of this paper, which is of interest to statisticians and biometricians, is to show by direct determinantal analysis certain relations known and unknown between the higher multiple and partial correlation coefficients.

**On the application of "goodness of fit" tables to test regression curves and theoretical curves used to describe observational or experimental data**, K. PEARSON (*Biometrika, 11 (1916), No. 3, pp. 239-261, fig. 1*).—This is a discussion of the "goodness of fit" and its application in statistics and physics.

---

<sup>1</sup> *Biometrika*, 10 (1914), p. 570.

On the "best" values of the constants in frequency distributions, KIRSTINE SMITH (*Biometrika*, 11 (1916), No. 3, pp. 262-276, figs. 2).—This is a comparison of the methods of moments and least squares in determining the values of constants in frequency distributions. It is concluded that if the definition of the "best" is made somewhat arbitrary the use of the method of moments is justified.

Berseem as a forage plant, J. B. PIOT (*Bul. Union Agr. Égypte*, 14 (1916), No. 114, pp. 14-22, fig. 1).—Successful experiments are reported in feeding berseem, or Egyptian clover, to cattle in Egypt, resulting in material gains.

Silos and silage, E. W. SHEETS (*West Virginia Sta. Bul.* 157 (1916), pp. 313, figs. 4).—Notes are given on the advantages of silage, the essential features of a good silo, dimensions of silo to build, and types of silos in the State.

Unpublished experiments at the station have shown that in wintering steers wheat straw and cottonseed meal are superior to timothy hay as supplements to silage. The cost of producing silage in different parts of the State was found to vary from \$23.43 to \$35.60 per acre while the yields varied from 10 to 10.3 tons per acre. The cost of producing timothy or mixed hay varied from \$7.04 to \$8.35 per acre, and the yields from 1.2 to 1.3 tons per acre. It is stated that the greatest value of silage is that it reduces to one-third the crop land necessary to feed or winter a given number of animals.

Pea-cannery refuse, M. ROSBY (*Country Gent.*, 81 (1916), No. 30, p. 1403, fig. 1).—A general discussion of the feeding value of pea-cannery refuse. The vines may be preserved either by stacking or by ensiling. It is stated that pea-vine silage is superior in some ways to corn silage, being higher in protein content and but slightly lower in carbohydrate content. Excellent results have been secured in feeding this silage to sheep, a rapid growth and fine quality of mutton being claimed.

Commercial feeding stuffs and registrations for 1916, C. S. CATHCART ET AL. (*New Jersey Stat. Bul.* 295 (1916), pp. 95).—Tabulated results are given of analyses of 1,102 samples of feeding stuffs inspected during 1915, including alfalfa meal, blood meal, brewers' dried grains, buckwheat feed, buckwheat middlings, buckwheat offal, coconut meal, copra cake meal, cottonseed meal, corn bran, corn meal, gluten feed, gluten meal, corn and cob meal, distillers' grains, dried beet pulp, feeding flour, fish scrap, hominy meal and feed, linseed meal, malt sprouts, meat scrap, oat hulls, peanut meal, rye bran, rye feed, rye middlings, screenings, wheat bran, wheat feed, wheat middlings, and mixed and proprietary feeds. A list of manufacturers who have registered feeding stuffs for sale during 1916 is included.

[Animal husbandry work] (*Kansas Sta. Rpt.* 1915, pp. 34-38).—At the Fort Hays substation during the winter of 1914-15 100 high-grade yearling heifers were wintered in four different lots to determine the comparative value of Sudan hay, Kafir corn stover, damaged alfalfa, and sorghum butts. The animals had access to wheat straw at all times. All of the feeds proved to be satisfactory roughages when fed in connection with a small amount of linseed meal. The cost of wintering for 120 days varied from an average of \$6.84 to \$7.53 per head for the different lots.

During the same winter 64 mature beef cows were fed Kafir corn silage, Kafir corn butts, wheat straw, and alfalfa hay supplemented with linseed meal or cottonseed cake. The average cost per head for wintering these cows was \$8.36 and they furnished a market for a large amount of feed which would otherwise have gone to waste.

Two lots of 30 high-grade Hereford heifer calves each were placed on an experiment in the fall of 1913. One of these lots was so fed as to produce a maximum growth and the other lot was maintained in ordinary range condition. At

the close of the second year's feeding there was a difference of 53 lbs. in the average weight of the heifers maintained in range condition as compared with those that had been wintered under more nearly ideal conditions. The average cost of this additional growth was \$6.97 per head.

The results of a feeding experiment with pigs during the winter of 1914-15 indicate that corn is slightly superior to any of the grain sorghums, its use resulting in more rapid gains and a higher finish. There was very little difference between the value of Kafir corn, feterita, and milo maize. Kaoliang did not prove to be very palatable. The feeding of whole threshed Kafir corn resulted in a great waste of feed, while the feeding of Kafir corn in the head proved to be advisable where facilities for grinding it are not present on the farm.

**Inheritance of color and horns in blue-gray cattle,** O. LLOYD-JONES and J. EYVARD (*Iowa Sta. Research Bul. 30 (1916), pp. 67a-106a, figs. 10*).—Data that have accumulated for 13 years at the Iowa Station on color and horn inheritance in crosses between Galloway and Shorthorn cattle are presented. Preliminary reports of progress have been reported by E. N. Wentworth (*E. S. R., 28, p. 572*).

A detailed discussion is offered of the color and polled or horned condition as seen in the parent breeds and the offspring resulting from the crosses in these experiments, together with suggestions as to the genetic relationship as to these characters.

Since 1906 when the inheritance studies reported were undertaken 24 dams as follows have been used: Four Shorthorns, 5 F<sub>1</sub> blue-gray (from white Shorthorn bull × Galloway cows), 3 Galloways, and 12 others of various generations and descriptions. The sires in use have been a blue-gray polled F<sub>1</sub> (from white Shorthorn bull × Galloway cow), a red polled F<sub>2</sub>, and red, roan, and white Shorthorn bulls. In all, 71 calves have been produced which are included in the present work.

The authors conclude that "the nature of black and red pigment in cattle as an independent allelomorph pair of characters is clearly indicated. White animals appear to be the result of pigment in a restricted condition, due to the absence of the factor *E* for extension. The restricted pigment may be either black or red in color. No extracted animal white with red ears has yet appeared. The whites with black ears, a novelty in this experiment, are similar in pattern to the Park Cattle of Britain, but it is doubtful if they can be considered genetically comparable to them.

"A satisfactory explanation of the genetics of roan color in cattle has not yet been made. A roan-producing factor *N* has been tentatively assumed to exist, but the results secured from these experimental matings agree almost equally well with the interpretation of roan as a heterozygote between white and colored. This would make the factor *N* unnecessary, for the roan condition would appear in all animals that were heterozygous for extension, that is *Ee*, without the aid of any other factor.

"The published data on the inheritance of horns in cattle are reviewed and new data presented. The present results substantiate the allelomorph nature of the horned and polled condition in cattle, and give no evidence that sex is in any way connected with the inheritance of these characters."

A bibliography is included.

**Feeding range steers,** L. FOSTER and H. H. SIMPSON (*New Mexico Sta. Bul. 101 (1916), pp. 24, figs. 10*).—This bulletin gives the results of feeding experiments conducted in 1909 and 1910 with range steers.

In the first experiment, which lasted 91 days from January 8, 1909, a comparison was made of the feeding values of barley, corn, and Kafir corn, each

being supplemented with 2 lbs. cottonseed meal daily. A comparison was also made in this test of corn stover and Kafir corn stover for replacing a part of a roughage ration of alfalfa. Five lots of 5 high-grade Hereford and Shorthorn yearling range steers, averaging about 600 lbs. each in weight at the beginning of the test, were used. In the second test, which lasted 90 days from January 19, 1910, the effort was made to find the most economical method of fattening range steers under New Mexico conditions, with home-grown feeds or with those most readily available. In this test there were 4 lots of 5 high-grade Hereford and Shorthorn yearling steers, each averaging about 200 lbs. lighter per steer than those in the 1909 test.

The rations compared and some of the results obtained are given in the following table:

*Steer feeding tests.*

Year.	Variable portion of daily ration.	Average daily gain per head.	Cost of feed per pound of gain.	Profit per steer.
		<i>Pounds.</i>	<i>Cents.</i>	
1909	20 pounds alfalfa hay, 8 pounds barley.....	2.04	9.52	\$9.62
1909	20 pounds alfalfa hay, 8 pounds corn.....	2.11	9.32	9.91
1909	20 pounds alfalfa hay, 8 pounds Kafir corn.....	1.95	9.90	9.07
1909	10 pounds alfalfa hay, 10 pounds shredded corn stover, 8 pounds Kafir corn.....	2.01	9.25	10.15
1909	10 pounds alfalfa hay, 10 pounds shredded Kafir corn stover, 8 pounds Kafir corn.....	1.84	10.47	8.39
1910	Alfalfa hay, corn stover, ad lib.....	1.39	3.98	6.93
1910	Alfalfa hay, ad lib.....	1.84	4.14	8.30
1910	Alfalfa hay, ad lib., 8 pounds corn.....	2.58	5.99	6.58
1910	Alfalfa hay, ad lib., 10 pounds corn (last 30 days only).....	2.06	5.01	7.44

The corn, barley, and Kafir corn in all the rations were ground. The feeds used in the experiments were estimated at the following prices: Ground corn, Kafir corn, and barley \$30 per ton; cottonseed meal, \$35 per ton; alfalfa hay, \$10 per ton; shredded corn stover and Kafir corn stover, \$6 per ton. The initial value of the steers per pound was 5.9 cts. in 1909 and 7.49 cts. in 1910, and the selling value in each case 8 cts.

In the 1909 experiment the steers rejected an average of 2.5 per cent of the alfalfa hay, 26.8 per cent of the corn stover, and 18.9 per cent of the Kafir corn stover.

Pasturing sheep on alfalfa, B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1915, p. 14, fig. 1*).—Beginning August 28, 1915, 10 lambs with an average weight of 75 lbs. each were pastured for 40 days on a 1-acre field of third-crop alfalfa. The pasture was divided into two lots, which were pastured alternately. During this time the lambs made an average gain of 0.39 lb. each per day, so that, with the gains worth 7 cts. a pound, a return of \$10.85 per acre was secured for 40 days' use of the alfalfa pasture. No bloating occurred.

Sheep feeding experiment (*Kansas Sta. Rpt. 1915, pp. 25, 26*).—Results are given of a feeding experiment which lasted from October 30 to December 20, 1914, with 313 western range lambs to determine the comparative value (1) of corn and Kafir corn as grain, (2) of alfalfa and cowpea hay as roughage, (3) of sorghum as silage or hay, and (4) of ground *v.* unground Kafir corn.

The lambs, which averaged about 55 lbs. each, were divided into six lots and so fed as to make a maximum use of the roughage. Daily rations, in addition to 0.19 lb. of cottonseed meal per lamb which was given to all the

lots, and some of the results of the experiment, are given in the following table:

*Lamb feeding experiments with different rations.*

Lot.	Variable portion of ration per lamb.	Average daily gain.	Cost per pound of gain.	Final value per pound.	Average profit per lamb.
		Pounds.	Cents.	Cents.	
1	0.89 pound corn, 1.35 pounds alfalfa hay, 1.09 pounds sorghum silage.....	0.40	5.60	8.05	\$1.02
2	0.9 pound corn, 1.53 pounds cowpea hay, 1.09 pounds sorghum silage.....	.35	6.19	8.05	.82
3	0.9 pound corn, 1.36 pounds alfalfa hay, 0.43 pound sorghum hay.....	.39	5.52	8.00	.99
4	0.9 pound corn, 1.78 pounds alfalfa hay.....	.39	5.73	7.90	.86
5	0.9 pound Kafir corn, 1.36 pounds alfalfa hay, 1.09 pounds sorghum silage.....	.35	6.03	7.90	.73
6	0.9 pound ground Kafir corn, 1.36 pounds alfalfa hay, 1.09 pounds sorghum silage.....	.36	6.18	8.05	.84

In figuring the cost of gains and profits the feeding stuffs were priced as follows per ton: Shelled corn, \$25; Kafir corn, \$22; ground Kafir corn, \$24; cottonseed meal, \$26; alfalfa hay, \$10; cowpeas, \$8; sorghum hay, \$6; and sweet sorghum silage, \$4. The lambs cost 7.3 cts. per pound delivered at the station, and the final values per pound in the above table are 0.6 ct. per pound lower than market prices to cover the expense of shipping to market.

[Feeding experiments with lambs] (*California Sta. Rpt. 1916, pp. 53, 55*).—In a comparison of spineless cactus and corn silage for fattening lambs, F. W. Woll found that the silage produced 17 per cent more gain with 10 per cent less feed than the cactus ration. It required about 10 days to get the lambs to eat the cactus readily.

In a test in which 125 lambs were allowed to graze upon a barley stubble field at the rate of 1 lamb per acre for a period of five weeks, R. F. Miller found that they made an average gain of 11 lbs. each, making the stubble field worth about 75 cts. per acre. The barley yielded 25 sacks per acre, and had been harvested with a combined harvester.

These lambs were then separated into lots in a feed lot and fed barley and alfalfa hay as a basal ration, supplemented with cottonseed meal, coconut meal, alfalfa meal, and molasses, respectively, one lot being fed a commercial feed, alfalfa meal, and molasses alone. The coconut-meal lot made the most economical gains, the cottonseed-meal lot being next. Alfalfa meal and molasses proved to be an expensive feed at \$18 per ton.

In another experiment with lambs, corn silage, milo maize silage, and sweet sorghum silage as supplements to alfalfa hay and barley were compared, and one lot was fed alfalfa hay alone. In economy of gain the ration containing milo maize silage ranked first and that containing sorghum silage second. The alfalfa hay lot made only about one-half the gains that the other lots made.

The use of hogs in disposing of crops, F. KNORR (*U. S. Dept. Agr., Bur. Plant Indus., Work Scottsbluff Expt. Farm, 1915, pp. 12, 13*).—Continuing previous work (*E. S. R., 34, p. 228*), during the season of 1915 hogs were pastured on alfalfa from early spring until September, being fed a supplemental ration of 2 lbs. of corn per 100 lbs. of live weight. They made gains of 2,976 lbs. per acre of pasturage and consumed 2.53 lbs. of corn per pound of gain. Valuing the gains at 7 cts. per pound and the corn at 60 cts. per bushel, there was a net return of \$132.84 per acre for the season, an equivalent of \$29.54 a ton for the 1915 alfalfa hay crop. The three-year average has been \$24.40 per ton,

Corn plats hogged down in 1915 produced a gain of 212 lbs. of pork, live weight, per acre, as compared with 1,052 lbs. in 1914, 1,008 lbs. in 1913, and 628 lbs. in 1912. The low gains in 1915 were due to the fact that the corn plats were severely damaged by hail.

[**Pasturing alfalfa and corn with hogs**], B. AUNE (*U. S. Dept. Agr., Bur. Plant Indus., Work Belle Fourche Expt. Farm, 1915, pp. 11-14*).—Continuing experiments previously noted (*E. S. R., 33, p. 871*), one lot of fall pigs grazing on alfalfa, and also fed during the pasture season 4,787 lbs. of corn per acre of alfalfa, gave a net return per acre in 1915 of \$60.32. Another lot of pigs, fed 4,976 lbs. of corn per acre of alfalfa, gave a net return of \$62.97 per acre of alfalfa grazed. In these two tests it took 2.36 lbs. of corn to produce 1 lb. of gain. The corn was charged at \$1.70 per 100 lbs., and a value of 7 cts. per pound was given to the pigs.

In hogging down corn, one plat with an estimated yield of 40.6 bu. of corn per acre produced pork at the rate of 548 lbs. live weight per acre. Another plat with an estimated yield of 34 bu. of corn per acre produced pork at the rate of 451 lbs. live weight per acre.

[**Pasturing alfalfa and corn with hogs**], D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1915, pp. 9-11, fig. 1*).—Continuing previous experiments (*E. S. R., 33, p. 429*), hogs pastured on alfalfa in 1915 gave a return of \$75.88 per acre during the pasturing season, an equivalent of \$10.84 per ton for the alfalfa hay crop. In this test the hogs were given a supplemental ration of 2 lbs. of corn per 100 lbs. of live weight.

Corn with an estimated yield of 52.41 bu. per acre when hogged down produced 864 lbs. of pork, live weight, per acre. The hogs consumed 3.4 lbs. of corn per pound of gain and made an average daily gain per head of 2.16 lbs.

[**Feeding experiments with pigs**], J. I. THOMPSON (*California Sta. Rpt. 1916, p. 55*).—In experiments in which wheat shorts, coconut meal, tankage, and cull beans were fed in conjunction with alfalfa pasture, self-feeders proved superior to hand-feeding. Coconut meal was an economical supplement to barley, but produced severe scouring when fed in considerable amounts. Cooked culled beans produced cheap gains, but a soft low-dressing product.

In a test in which the effects of feeding raisins to swine were studied 3 lots of 8 5-months' old pigs were fed raisins, raisins and barley, or barley alone, respectively, alfalfa meal being fed, in addition, to each lot. When constituting the entire concentrated part of the ration, raisins produced slow gains and considerable scouring resulted. When barley and raisins were fed in equal parts the raisins showed nearly the same feeding value as barley.

**The physiological effect upon work horses of alfalfa hay cut at different stages of growth** (*Kansas Sta. Rpt. 1915, pp. 16, 17*).—This is a brief report of one year's work in an investigation undertaken in 1914 to determine (1) the effect upon stand and yield when alfalfa is harvested at different stages of growth; (2) the variation in the amount of total nutrients and fertility elements in the hay cut at different stages of growth; and (3) the physiological effect upon horses fed the different alfalfa hays.

The largest yield was obtained from the alfalfa cut at the time of bud formation, and each successive stage gave a smaller yield. No effect on the stand was noticed this first year. The alfalfa cut in the bud stage had the largest percentage of ash and crude protein and the smallest percentage of crude fiber and nitrogen-free extract; the first two decreased in each successive stage, and the last two increased. It also gave the largest total yield of all nutrients per acre. It had the largest percentage of nitrogen, phosphorous, and potassium, and all these decreased in the successive stages. The alfalfa hay

cured in the sun had a larger percentage of pure protein than that cured in the shade.

In feeding the different alfalfa hays to horses no material difference in physiological effect was noticed.

**Growing draft colts.** C. W. McCAMPBELL (*Kansas Sta. Rpt. 1915, pp. 54-69, figs. 16*).—An experiment was started in January, 1913, the objects of which were to determine (1) whether the good draft colts can be grown without the use of oats, (2) the cost of developing draft colts under ordinary Kansas conditions, and (3) the type of colt which usually develops into the largest horse.

The results of the experiment show that "the colts receiving a grain ration of 70 per cent of corn, 25 per cent of bran, and 5 per cent of oil meal made a daily growth of 1.023 lbs. during the entire period of 720 days, while the colts receiving oats made a daily growth of only 0.926 lb. Each pound of growth during the entire period made by the colts receiving corn, bran, and oil meal cost 15.04 cts., while each pound made by the colts receiving oats cost 18.6 cts.

"The colts made more rapid growth during the first year after weaning than during the second year. The first year's daily growth averaged 1.285 lbs. and the second year's daily growth 0.7 lb. Although the total cost of feeds consumed during the first year was greater than that during the second year, the growth was cheaper. The average cost of each pound of growth during the first year was 14.2 cts., and during the second year 23 cts.

"The average total cost of developing the grade colts from the time they were approximately eight months old until they were ready to work (2.5 years) was \$123.37. The cost of raising a draft colt to the age of eight months is about \$50, making the total cost (including the labor) until the colt is ready to work approximately \$175, under conditions and prices similar to those of 1913-1914.

"The colts showing considerable bone and stretch at weaning time developed into the largest horses. The plump, mature-looking weanlings are still plump little horses."

**Philippine horses.** D. B. MACKIE (*Jour. Heredity, 7 (1916), No. 8, pp. 373-382, figs. 4*).—The author maintains that the Philippine horse is not, as popularly supposed, a descendant of horses brought to the islands from Mexico and Spain by the Spaniards, but that the bulk of the animals brought in by the early colonists were Chinese. It is shown that horses existed in parts of the archipelago prior to the Spanish conquest, and the ancestry of these is traced to Malaysia. In addition to China other channels hitherto almost unknown have poured equine blood into the Philippines, so that the horses of the islands to-day contain large or small amounts of characters from Chinese, Japanese, Mexican (including various races entering into the race so designated), Persian, Indian, and Sumatran sources.

[Poultry investigations], J. E. DOUGHERTY (*California Sta. Rpt. 1916, p. 58*).—Continuing experiments with high-protein animal and vegetable feeds (E. S. R., 34, p. 268), the results to date indicate that it makes little difference what kinds of such feeds are fed so long as the ration contains some animal feed, has an approximately correct nutritive ratio, and contains feeds suitable to poultry.

It was found to be economical to use some animal feed in the ration, but mashes containing as low as 7.7 per cent meat scrap gave us good results as those containing much higher percentages. Where fowls had free access at all times to hoppers of meat scrap and soy bean meal in addition to the basic mash, they ate 10.55 lbs. of meat scrap and 12.7 lbs. of soy-bean meal per hen per year, as compared with 1.8 to 3.6 lbs. of soy-bean meal and meat scrap, respectively, in other pens where the animal and vegetable high-protein feeds

were mixed in varying proportions with the mash. Yet the fowls consuming the greater amounts of high-protein feeds laid no better. This would indicate that fowls can not be trusted to balance their ration.

[Poultry investigations] (*Massachusetts Sta. Rpt. 1915, pt. 1, pp. 29a, 30a, 48a-50a*).—From investigations connected with the factors which influence egg production H. D. Goodale concludes that the prime factor essential for satisfactory winter egg production from strong stock is early maturity. The records of the station flocks show that, even in the case of birds of one breed hatched from eggs from the same pen supposedly made up of birds of similar breeding, the age at which the first egg is produced varied from 195 to 300 days. The prime factor essential for high egg production, aside from early maturity, was found to be nonbroodiness. Data show that when a hen becomes broody her egg production decreases about 40 per cent. The effort is being made to develop a nonbroody strain of Rhode Island Red hens.

The work of the year indicates that chicks reared on new land thrive better than those raised on land upon which chicks have previously ranged, even if for only a short period of time.

### DAIRY FARMING—DAIRYING.

[Dairy husbandry studies], F. W. WOLL (*California Sta. Rpt. 1916, pp. 52, 53*).—Confirming results already noted (*E. S. R., 34, p. 269*), data obtained during the year indicate that the feeding of barley does not tend to reduce milk flow. It was found, however, that most cows do not do so well on barley alone as on mixed grain rations.

Heifers fed alfalfa and mixed rations dropped somewhat heavier calves and produced during their first lactation period a marked increase in milk and milk fat as compared with heifers fed alfalfa only.

In an experiment with spineless cactus for milch cows, the amounts of the cactus that the cows could be induced to eat were so small that the nutrients supplied formed only an insignificant part of the rations. Analyses are given of the cactus slabs.

•Carrying capacity [of irrigated pastures], D. HANSEN (*U. S. Dept. Agr. Bur. Plant Indus., Work Huntley Expt. Farm, 1915, pp. 14-16, figs. 2*).—Two milch cows were pastured for 164 days in 1915 on three-quarters of an acre of mixed grass irrigated pasture (*E. S. R., 33, p. 429*), during which time they were given 882 lbs. of grain and 1,630 lbs. of alfalfa hay as supplemental feed. During this time they produced 5,247 lbs. of milk and 213.7 lbs. of milk fat. Valuing the alfalfa hay at \$6 per ton, grain at \$25 per ton, and the 213.7 lbs. of milk fat at \$52.07, there was a return of \$48.20 per acre for the pasture.

In testing the value of irrigated pastures during the first year after seeding a quarter-acre plat was seeded without a nurse crop during the spring of 1915 with a mixture of awnless brome grass, orchard grass, meadow fescue, Kentucky bluegrass, perennial rye grass, tall fescue, and white clover. During the latter part of the season this plat furnished abundant grazing for one heifer for 58 days, during which time a gain of 114 lbs. was made, an equivalent at 5 cts. per pound of gain of \$22.80 per acre for the pasture. No bad effects of the early grazing upon the grasses were apparent at the close of the season.

The cost of producing goat milk, E. C. VOORHIES (*California Sta. Rpt. 1916, pp. 52, 53*).—Two young purebred Toggenburg milch goats produced during the past year 1,553.2 lbs. of milk containing 45.01 lbs. of fat, and 1,341.6 lbs. of milk containing 38.67 lbs. of fat, respectively. The cost of feed eaten by the goats during the year at ordinary market prices amounted to \$12.64 and \$10.71.

respectively, making the feed cost per gallon of milk 6.8 cts. and 6.9 cts. for the two goats.

Further studies of the relation of the quality of proteins to milk production, E. B. HART, G. C. HUMPHREY, and A. A. SCHAAL (*Jour. Biol. Chem.*, 26 (1916), No. 2, pp. 457-471, figs. 4).—Continuing the study previously noted (E. S. R., 33, p. 275), data on the comparative value for milk production of the proteins of gluten feed, oil meal, distillers' grains, casein, and skim-milk powder are reported. Fifty per cent of the total digestible proteins of the ration was furnished by these concentrates, which were used to supplement a basal ration of corn stover, corn silage, and corn meal. The total protein intake constituted about 10 per cent of the dry matter of the ration, and the nutritive ratio was approximately 1:8.

"With a daily production of 40 to 45 lbs. of milk carrying 10 to 12 per cent of total solids, negative nitrogen balance persisted throughout the experiment of 16 weeks' duration. Only during the period of skim-milk powder feeding was one of the animals storing nitrogen. In spite of this long negative balance milk secretion continued at the expense of catabolizing tissue. The total yield and total solids of the milk declined slightly after two months of continuous negative nitrogen balance."

A marked difference in the utilization of the concentrates was observed, gluten feed showing a percentage efficiency of 45, oil meal 61, distillers' grains 60, casein 59, and skim-milk powder 60. These data represent the efficiency in the mixture used.

"Possible errors in calculation may arise from the supplementing effect of the catabolizing tissue, thereby raising the figures above their true value, but nevertheless they do have comparative worth. Other roughages will be used in a further study of this problem.

"These studies furnish additional evidence that the nutritive ratio or plane of protein intake for milk production may vary according to the nature of the concentrates and basal ration used."

Cooling hot-bottled pasteurized milk by forced air, S. H. AYERS, J. T. BOWEN, and W. T. JOHNSON, JR. (*U. S. Dept. Agr. Bul.* 420 (1916), pp. 38, figs. 20).—In continuation of investigations previously noted (E. S. R., 31, p. 275), experiments are reported the object of which was to ascertain whether hot-bottled pasteurized milk can be successfully cooled by forced air under commercial conditions. Data are also given on the heating of cold-bottled milk by means of circulated hot air.

The cooling experiments were conducted on a 30-crate basis, 15 for quart bottles and 15 for pints, with a specially designed experimental apparatus which is illustrated and described. A description is also given of the instruments and method of recording data. On account of the small variation in the relative rate of the cooling of water and milk, water was mainly used in these experiments. Bottles of milk were distributed throughout the crates, however, for bacteriological studies as well as for temperature readings. Temperature readings were also taken in the bottles of water.

To compare the rate of cooling bottles and cans containing milk when exposed to still air and to moving air, pint and quart bottles and 10-gallon cans of milk were placed in a refrigerated room, the temperature of which was held at about 40° F. In still air it required 4½ hours to reduce the temperature of milk in pint bottles from 142 to 50°, while in circulating air, where the air was forced in a horizontal direction over the containers at a velocity of 1,250 ft. per minute and at a temperature of about 40°, the corresponding time required was 1 hour and 27 minutes. With quart bottles of milk under the same conditions the

relative rate of cooling for bottles exposed to still air and moving air was the same as that for pint bottles, but the time required for cooling through the above range was longer. In a room temperature of  $42^{\circ}$  milk in the 10-gallon cans was reduced from  $147$  to  $90^{\circ}$  in  $6\frac{1}{2}$  hours in still air and in 2 hours and 15 minutes in moving air.

In cooling experiments performed on a 30-crate basis in which the air was forced from the bottom upward, it was found that the variation in temperature in different sized bottles and the same sized bottles at different positions in the stack was too great for satisfactory commercial operation. Consequently in the next experiments the direction of the air through the stack was reversed periodically, the cold air being blown through from the bottom for 15 minutes and then through from the top for the same period. It was found that while the difference in temperature between the top and bottom bottles was decreased to a certain extent by reversing the air, still there was too great a difference for satisfactory operation commercially.

In experiments in which the air was forced from the top downward it required 2 hours and 10 minutes to reduce the temperature of the lower quarts to  $50^{\circ}$  when the temperature of the incoming air was  $40^{\circ}$ ; 1 hour and 35 minutes when the temperature of the incoming air was  $30^{\circ}$ ; and 1 hour and 20 minutes when the temperature of the incoming air was  $20^{\circ}$ . In these experiments with the incoming air temperature at  $40^{\circ}$  the average difference in temperature between the lower quart and upper pint at the end of the cooling period was  $8.9^{\circ}$ , and with the incoming air at  $30^{\circ}$  the average difference was  $2.49^{\circ}$  and maximum difference  $4.5^{\circ}$ .

When a bottle was cooled by an air blast from the bottom of the stack there was a difference in temperature between the top and bottom of the bottle of about  $8^{\circ}$  when the fan was started and  $23^{\circ}$  22 minutes later. When the air was forced downward through the crate of bottles this difference between the top and bottom of individual bottles was practically eliminated.

In experiments on the cost of cooling by means of cold outside air it was found that under the conditions of the experiments and assuming a cost of 6 cts. per kilowatt hour for electric energy, the cost of power per ton of refrigeration was \$1.11. Under commercial conditions it is estimated that the cost would be only about 66 cts. per ton of refrigeration. These figures are based on an outside air temperature of  $40^{\circ}$  or lower.

In order to obtain data on the effect of slow cooling on the bacterial content of milk after pasteurization, ten experiments made in which milk was first pasteurized and bottled hot in steamed bottles. For the ten bottles cooled within one-half hour in ice water the average number of bacteria per cubic centimeter was, directly after pasteurization, 5,823; after  $17\frac{1}{2}$  hours in the refrigerator at  $45^{\circ}$ , 5,040; and taken from the refrigerator 18 hours after pasteurization and held for 6 hours at  $75$  to  $86^{\circ}$ , 6,908. For the ten bottles of milk cooled slowly at room temperature for four hours the average number of bacteria per cubic centimeter was, directly after pasteurization, 5,727; after 14 hours in the refrigerator at  $45^{\circ}$ , 4,678; and taken from the refrigerator 18 hours after refrigeration and held for 6 hours at  $75$  to  $86^{\circ}$ , 5,583. The average bacterial content of the ten samples of raw milk in this experiment was 264,375 per cubic centimeter. On checking these results in a test with pasteurized milk cooled on a small commercial scale it was found that when the bacterial content of raw milk was high there was a marked reduction in the number of bacteria during the process of cooling by forced air circulation. However, the authors state that the period of cooling to  $50^{\circ}$  should not exceed five hours,

and to provide a wide margin of safety they recommend that the milk be cooled within 3 hours after it is bottled.

In laboratory experiments on a 30-crate basis it was found that slow cooling of hot-bottled pasteurized milk had no detrimental effect on the cream line and the flavor of the milk. In these experiments the milk was pasteurized at 145° and the cooling period was not longer than three hours.

In experiments upon heating bottled milk by means of forced air it was found that the pint and quart bottles in similar positions and the same sized bottles in different positions in the stacks were heated unevenly. It was impossible to heat the bottles to the pasteurizing temperature of 145° without overheating some of them. The experimental apparatus used in heating the milk in bottles by means of circulated hot air is illustrated and described.

**Grading and labeling of milk and cream** (*Boston: Boston Chamber Com., 1916, pp. 24, figs. 44*).—This pamphlet describes the system of grading and labeling milk and cream in use in various cities in the United States, and contains suggestions for grading and labeling. Notes are also given on standardization and systems of buying milk.

**Butter making**, L. M. DAVIS (*California Sta. Rpt. 1916, p. 48*).—Butter kept in cold storage for three months showed a shrinkage of 0.6 per cent. Soaking parchment wrappers in a strong salt (NaCl) solution for several hours before using generally prevented moldy growth in butter, due to contamination from wrappers.

It was found that mold does not grow in butter containing 2 per cent or more of salt. It is stated that a good grade of butter can be made from cream possessing a minimum butter fat standard of 35 per cent and an acidity of 0.45 per cent from May to November, and 0.35 per cent from November to May, unless the cream is of bad flavor.

**Cheese making**, H. S. BAIRD (*California Sta. Rpt. 1916, p. 48*).—It was found more difficult to make a good grade of cheese from milk produced under ordinary conditions during the summer months than during the spring and late winter months, even where uniform methods prevail. Attempts to prevent mold growth on cheese held in a poorly ventilated refrigerating room by washing the cheese, walls, and shelves with a solution of corrosive sublimate and fumigating the room by burning sulphur were unsuccessful. Artificial circulation of air by means of a fan checked the growth of mold to some extent.

**The manufacture of cheeses with a definite fat content in the dry substance**, K. WINDISCH (*Württemberg. Wechnbl. Landw., 1916, Nos. 9, pp. 146, 147; 10, pp. 160, 161*).—This article discusses the preparation of various kinds of cheese with a definite fat content in the dry matter of the finished product by regulating the fat content of the kettle milk.

The following formulas for mixing a kettle milk of any desired fat content are submitted:

$$x = \frac{100(k-m)}{v-k}; y = \frac{100(v-k)}{k-m};$$

$v$ =fat content of the whole milk;  $m$ =fat content of the skim milk;  $k$ =the desired fat content of the kettle milk;  $x$ =liters of whole milk which must be added to 100 liters of skim milk to obtain the kettle milk of desired fat content; and  $y$ =liters of skim milk which must be added to 100 liters of whole milk to obtain the desired fat content of the kettle milk.

For the preparation of a Limburger cheese containing 15 per cent fat a kettle milk of 0.7 per cent fat content is required. For a 40 per cent fat content Limburger cheese a 2.4 per cent kettle milk is necessary, for an Emmental cheese

containing 40 per cent fat a kettle milk of at least 2.7 per cent fat, and for a 50 per cent fat content Camembert a kettle milk of from 3.5 to 3.6 fat content.

It is indicated that information of this nature is of value in view of the recent legislation in Germany in regard to the preparation and sale of cheeses of specified standards.

The milking machine a source of bacterial contamination of milk, G. F. RUEDIGER (*Jour. Infect. Diseases*, 19 (1916), No. 4, pp. 652-654).—Experimental data are submitted which indicate that milk may be badly contaminated by a milking machine if the teat cups and rubber tubes are not carefully cleaned and scalded before each milking. The use of chlorinated lime or like material does not satisfactorily prevent bacterial growth in the tubes.

It is further indicated that a mere inspection of the dairy without bacteriological control of the milk may fail absolutely to locate an insanitary process in the production of the milk.

Ice cream, L. M. DAVIS (*California Sta. Rpt.* 1916, p. 48).—The author reports that "there was no uniform relation between the consistency of an ice-cream mix and the percentage of swell where different thickeners were used. Increasing the consistency of the ice cream in the freezer by rapid freezing reduced the percentage of swell. Decreasing the amount of sugar in the ice-cream mix below normal increased the percentage of swell, but produced an unfavorable effect upon the finished product from the standpoint of flavor and texture. Increasing the amount of sugar in the ice-cream mix above normal decreased the percentage of swell, and, while it produced a better texture, resulted in ice cream which was too sweet. The consistency of an ice-cream mix can be increased by the use of thickeners to a point where the percentage of swell will be materially decreased."

## VETERINARY MEDICINE.

Veterinary bacteriology, R. E. BUCHANAN and C. MURRAY (*Philadelphia and London: W. B. Saunders Co., 1916, 2. ed., pp. 590, figs. 209*).—This is the second edition of a volume by the senior author, previously noted (*E. S. R.*, 26, p. 276). Many chapters have been completely rewritten and several new ones added. The organisms have also been regrouped in accordance with more recent conceptions of relationships.

Bacteriology.—General, pathological, and intestinal, A. I. KENDALL (*Philadelphia: Lea & Febiger, 1916, pp. X+17-651, pls. 9, figs. 98*).—This volume is divided into five general sections: General bacteriology; pathogenic bacteria; higher bacteria, molds, yeasts, filterable viruses, and diseases of unknown etiology; gastro-intestinal bacteriology; and applied bacteriology. Special emphasis is laid on the chemistry of the activity of the micro-organisms.

A text-book upon the pathogenic bacteria and protozoa, J. McFARLAND (*Philadelphia and London: W. B. Saunders Co., 1916, 8. ed., rev., pp. 807, pls. 3, figs. 322*).—The eighth revised edition of the work previously noted (*E. S. R.*, 28, p. 78).

The comparative resistance of bacteria and human tissues to certain germicidal substances, R. A. LAMBERT (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 18, pp. 1300, 1301).—A table giving results of a number of tests of the strengths of some common germicides necessary to kill bacteria and of the strengths necessary to kill tissue cells is submitted. Of the substances examined iodine was the only one by which the cells were not destroyed more easily than the bacteria. Mercuric chlorid, sodium hypochlorite (Dakin's solution), potassio-mercuric iodid, argyrol, and phenol did not exhibit any great difference, however.

The use of sugar as a dressing in veterinary surgery, G. BUSSANO (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Hyg.*, 33 (1915), Nos. 19, pp. 765-785; 20, pp. 810-816; 21, pp. 829-844+4, pls. 7; abs. in *Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 2, pp. 237-239).—The literature on the use of sugar in surgery and its physiological properties is briefly reviewed, and experiments are described in which cane sugar or glucose was applied to sutured or other wounds, especially in operations on the feet. In some experiments solutions of glucose were injected intraperitoneally, subcutaneously, and into the joint cavities, trachea, and jugular vein. Horses and mules were used in the experiments described.

The results obtained indicate that glucose (5 to 10 per cent) injected subcutaneously, intraperitoneally, and into the joints is absorbed in a short time without any disturbance other than a slight rise in temperature. More concentrated solutions (25 per cent) at a temperature of from 29 to 30° C. may be injected into the trachea or jugular vein with the double advantage of being more rapidly absorbed and easily tolerated. Amounts of from 500 to 1,000 cc. may be injected daily without any functional disturbance, and by repeating the injection for several days a considerable improvement in the general condition of the animal is obtained. Powdered sugar applied to any wound acts as an absorbent antiseptic, and at the same time stimulates the nutrition of the tissues by the formation of a granular layer and rapid healing. When applied directly on sutured wounds it protects them from possible infection by initiating rapid healing. In foot operations accompanied by more or less considerable loss of tissue, and especially in the partial or total separation of the hoof, dressings of sugar rapidly cleanse the wound and promote a rapid growth of horny tissue. The deodorizing property of sugar also makes it valuable as a dressing. The formation of pus seldom occurs, even with moderately dilute solutions. When applied to a discharging or suppurating wound the discharge rapidly diminishes, and ceases with successive applications.

Although successful results were obtained with both cane sugar and glucose the author recommends the latter for various reasons. Because of its absorbent, antiseptic, and healing properties, and also its low price, sugar is deemed to constitute a dressing of the first order.

**Colloidal chemistry and immunology**, M. VON KROGH (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 452-477, figs. 14).—This is a theoretical discussion of the relations between colloidal chemistry and immunology, from which the general conclusion is drawn that colloidal chemistry is an important factor in immunology, but only one of several. "As an isolated method it does not explain anything at all, but as a help to disentangle the complicated processes concerned it may be of immense service."

**An improved method for the concentration of antitoxic sera**, ANNIE HOMER (*Jour. Hyg. [Cambridge]*, 15 (1916), No. 3, pp. 388-400).—The following technique is outlined:

To the serum or plasma diluted with one-third or one-fifth its volume of water sodium chlorid is added to a concentration of from 1.5 to 2 per cent. The material is heated to a temperature of from 56 to 57° C. for 15 hours, or to from 57 to 58° for 8 hours. The heated plasma is made 50 per cent of saturation with ammonium sulphate, and the mixture heated to and kept at a temperature of 61° for a few minutes. It is then cooled to from 40 to 45° and filtered, the precipitate is washed with 33 per cent of saturation with ammonium sulphate, the washings, after being filtered, are added to the main bulk of the filtrate which is then saturated 50 per cent with ammonium sulphate, and the resulting precipitate is filtered off, pressed, and dialyzed. The pressed precipitate has a yellowish color as distinct from the bluish-green color

of Banzhaf's product. To the residues from dialysis the necessary amounts of salt and preservative are added. The final product in bulk is of a reddish-brown color and does not exhibit even a trace of opalescence.

No difficulty has been encountered in the filtration of these products through pulp or Pasteur-Chamberland filters. The addition of two or three times its bulk of 1 per cent saline does not impair the ease of its filtration.

The method is claimed to be an improvement on the Gibson-Banzhaf method<sup>1</sup> because of a saving of time, labor, and material; the potency of the finished product is nearly twice as great; and the total loss of antitoxic units need not be greater than 10 per cent. The procedure is also claimed to be superior to the Banzhaf<sup>2</sup> one-fraction process for similar reasons.

**The refinement and concentration of antitoxins,** P. G. HEINEMANN (*Jour. Infect. Diseases*, 19 (1916), No. 3, pp. 433-439).—A modified procedure for the preparation of a refined antitoxic serum of higher concentration than could be obtained by any of the earlier methods proposed is described in detail. The serum produced was water-clear (for at least one year) and produced no trace of sediment. It readily passes through Berkefeld filters, and is easily discharged through a hypodermic needle. The antitoxic globulins obtained by the new method are easily soluble, and dialysis is consequently rapid. "Plasma of 100 and 200 units can be used to advantage, thus being offset the additional expense of production. Nonantitoxic proteins are eliminated in large measure and serum disease, as far as present observations go, is greatly reduced."

A concentrated hog-cholera serum was prepared by the new method, 7 cc. of which afforded ample protection to exposure, while from 20 to 30 cc. of the original material was required.

**Another poisonous Claviceps,** J. B. S. NORTON (*Science*, n. ser., 43 (1916), No. 1121, pp. 894, 895).—The report of experiments by Brown and Ranck on the poisonous action of *Claviceps paspali* on Paspalum, previously noted (E. S. R., 34, p. 676), have led the author to record observations of a similar action of *Claviceps* found on *Paspalum leve* in Maryland. This fungus was first observed to be very abundant and conspicuous in the summer of 1902, in the autumn of which year a sample was received from a Maryland farmer who had taken it from a field where cattle had died with symptoms of poisoning. "The *Claviceps sclerotia* which replace the Paspalum grains are frequent in Maryland nearly every year, though in some years almost absent and sometimes, as in 1915, unusually abundant."

**Report of the veterinary director general for the year ended March 31, 1914,** F. TORRANCE (*Rpt. Vet. Dir. Gen. Canada, 1914*, pp. 147, pls. 10).—In addition to the main report of the veterinary director general (pp. 3-28), the reports of veterinary inspectors, etc., are given in 23 appendixes. Of these mention should be made of the following: Report of C. H. Higgins, pathologist at the biological laboratory at Ottawa (pp. 74-81); Epizootic Abortion Investigations.—Interim Report (pp. 82-88) and Strangles Vaccine (Experimental) (pp. 89-91), by T. C. Evans; Rabies and the Specificity of Negri Bodies (pp. 92-95), by A. B. Wickware; Avian Tuberculosis, by C. H. Higgins and A. B. Wickware (pp. 96-102), previously noted (E. S. R., 35, p. 576); Entero-hepatitis or Blackhead in Turkeys, by C. H. Higgins, A. B. Wickware, and N. M. Guiou (pp. 103-110); report of the pathologist at the veterinary research laboratory at Lethbridge, Alberta, E. A. Watson, on the serum test for dourine, etc. (pp. 111-116); An Outbreak of Dourine in the Unity District of Saskatchewan, by W. L. Hawke (pp. 117, 118); report of the pathologist at the veterinary research

<sup>1</sup> Collected Studies Research Lab. Dept. Health N. Y. City, 3 (1907), pp. 97-107.

<sup>2</sup> Loc. cit., 7 (1912-13), pp. 114-116.

laboratory at Agassiz, British Columbia, S. Hadwen (pp. 119-136), including A Study of Hematuria in France and Other Countries, etc., notes on Tick Paralysis Resulting from the Bites of *Dermacentor venustus* and on Warble Flies, etc.; and a Preliminary Note on the Effects of Feeding Rice Meal to Pigs, by P. H. Moore, Agassiz (pp. 137-140).

**Annual report of the veterinary service for the year 1914, W. LITTLEWOOD** (*Ann. Rpt. Vet. Serr., Egypt, 1914, pp. 49, pl. 1*).—This report deals with the occurrence and work of the year with contagious diseases of animals, the work of the veterinary pathological laboratory, etc.

The disinfection of tannery effluent containing anthrax spores, J. WINTERS-BERGER (*Wiener Tierärztl. Monatsschr., 2 (1915), No. 8, pp. 353-379*).—Experimental data submitted show that only in isolated cases and under the most favorable conditions is a complete disinfection possible by the use of from 0.1 to 0.2 per cent chlorid of lime solution after contact from two to four days. By the use of 0.5 per cent chlorid of lime anthrax spores could be destroyed in the majority of the tests reported in three days. Such results, however, were not consistently reproducible or uniform. The disinfectant value increases with the concentration of the material used, a complete destruction of anthrax spores being obtained in three days by the use of 2 per cent chlorid of lime.

It is indicated that since the conditions in practice are not so favorable as experimental conditions the use of the disinfectants of stronger concentrations and for prolonged periods of contact is the safest procedure.

The addition of hydrochloric acid markedly increased the disinfectant strength of the chlorid of lime, and the procedure is deemed to be of practical value. The economical aspect in cases where a highly alkaline water is used would, however, have to be considered in the use of the acid.

Formaldehyde was found to be more active than chlorid of lime, but the cost when used in concentrations of from 0.5 to 1 per cent would be a disadvantage.

The data obtained in the use of various lime-vat mixtures confirm earlier investigations that by their use a partial destruction of spores is possible if the period of contact is prolonged. The spent mixtures were, however, often found to contain virulent spores.

The earlier observation that chlorid of lime exhibits a greater affinity for dead organic matter than for living material was confirmed.

**The strength and composition of blackleg vaccines, O. M. FRANKLIN and T. P. HASLAM** (*Jour. Infect. Diseases, 19 (1916), No. 3, pp. 408-415*).—This is a report of investigations made at the Kansas Experiment Station on the strength and composition of some of the most widely known blackleg vaccines.

The results show that the powder-form vaccines must be given in amounts of from 20 to 150 mg. to kill a guinea pig. Most of the commercial pellets were not fatal to guinea pigs in doses of three pellets per animal. Pellets which are too virulent produce severe vaccination losses.

“The pseudoblackleg bacillus differs from *Bacillus chauvæi* in its pathogenicity in rabbits, in the formation of a putrefactive odor, in the size and appearance of the colony in pure culture, in the gas formula, in the blackening of iron-sulphate agar, in the pathogenicity in guinea pigs highly immune to blackleg, and in the failure of blackleg immune serum to protect guinea pigs against a lethal dose of pseudoblackleg culture or a B pellet.”

**The ophthalmic test for glanders, with a simplified method of procedure, N. S. FERRY** (*Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 1, pp. 41-46*).—The tests commonly used for the diagnosis of glanders and the requirements of a most satisfactory diagnostic test are briefly reviewed.

The method proposed by the author consists of preparing a desiccated mallein by precipitating the crude mallein with several volumes of absolute alcohol,

washing the precipitate with ether, and drying in vacuo. The purified material thus obtained is incorporated with lactose into small tablets in such proportion that each tablet contains the exact amount of mallein for one test. The test is performed by placing the tablet directly into the conjunctival sac at the inner canthus of the eye, where it quickly dissolves without any apparent discomfort or annoyance to the animal.

The simplified procedure described is claimed to fulfill the requirements of a most satisfactory test, as indicated by earlier investigators.

**An atypical case of rinderpest in a carabao, W. H. BOYNTON** (*Philippine Bur. Agr. Bul. 31 (1914), pp. 5, fig. 1*).—Previously noted from another source (*E. S. R., 31, p. 677*).

**The prophylaxis of tetanus by antitoxic serum, VAILLARD** (*Presse Méd. [Paris], No. 49 (1916), pp. 393, 394*).—The author briefly discusses various experiences in which tetanus developed months after injury and treatment with antiserum. Nonmotile spores, but with apparently unlimited vitality, were found in leucocytes six months after injury. These facts demonstrate that the spores are not destroyed by the antiserum, but only by being incorporated and digested in the leucocytes.

A wound infected with tetanus spores may develop tetanus long after it is apparently healed. The danger is greatest where an infected foreign body remains in the muscle tissue. The results of experiments under such conditions have shown it to be absolutely impossible to prevent infections with antiserum injections, the only apparent result being a delay in the onset of the disease.

The application of the experimental facts observed to the disease occurring in wounded soldiers is indicated, and a few instances discussed.

In conclusion it is emphasized that the biological phenomena are too complex for any prophylactic measures to be absolutely infallible.

**Researches in trichinosis, W. LINTZ** (*Med. Rec. [N. Y.], 90 (1916), No. 23, pp. 987, 988*).—This paper reports experiments in which pieces of muscle tissue containing numerous living trichinæ were fed to albino rats.

"The rats as a rule became very sick 10 to 20 minutes after feeding; they would not move around, although they were very lively previous to feeding, their heads would droop, they refused nourishment, the breathing became very rapid, and they would begin to waste away. These symptoms lasted about four days, when the rats began to recover, and in two or three days appeared apparently normal."

**Complement fixation in tuberculosis, H. J. CORPER** (*Jour. Infect. Diseases, 19 (1916), No. 3, pp. 315-321, figs. 2*).—The studies reported show that virulent cultures of tubercle bacilli, free from all foreign substances and suspended in sterile salt solution, undergo autolysis at incubator temperature, the autolysis reaching a maximum from the sixth to the eighth day. "During the autolysis of virulent cultures of tubercle bacilli there is a coincident liberation of antigenic substances, which possess advantages over a suspension of living virulent tubercle bacilli as antigen for complement-fixation tests in tuberculosis."

The examination of 361 cases in which both an emulsion and an autolyzate prepared from living virulent human bacilli were used as antigen indicated that the complement-fixation test is not absolute, being positive only in about 30 per cent of all the clinically definite cases of the disease, both active and inactive. Active cases give a higher percentage of positive results than inactive cases. The value of the test for tuberculosis lies in the fact that in conjunction with other findings a definitely positive reaction makes the diagnosis certain. It is of value also from a differential diagnostic standpoint in that it indicates tuberculosis when positive as against other complications.

A positive test was never obtained in the absence of a positive von Pirquet reaction. A large percentage of clinically normal individuals giving positive von Pirquet reactions, however, yielded negative fixation tests.

It is deemed that "the practical absence of a reaction in nontuberculous cases makes this test, when positive, of far greater value in the diagnosis of tuberculosis than any of the biologic tests for tuberculosis thus far discovered."

**Studies in immunization against tuberculosis**, K. and S. VOX RUCK (*New York: Paul B. Hoeber, 1916, pp. XVI+439*).—This volume is divided into three general parts: Theoretical considerations; practical immunization against tuberculosis; and experimental studies in the immunization against tuberculosis. Clinical and experimental data collected by the authors in their study covering a number of years are included.

**Tuberculosis in Normandy**, FRÉGER (*Bul. Soc. Cent. Méd. Vét., 92 (1916), No. 8, pp. 123-132*).—The prevalence and means of suppression of the disease are briefly discussed. The value of sanitary housing and stabling as prophylactic measures is strongly emphasized.

**Sheep diseases**, E. T. BAKER (*Chicago: Amer. Jour. Vet. Med., 1916, pp. 237, pls. 6, figs. 66*).—Following discussions of the history of the breeds (pp. 15-52), the anatomy of the sheep (pp. 53-62), hygiene (pp. 63-74), and medicines and their administration (pp. 75-83), the more important diseases, poisonous plants, predatory enemies, etc., of sheep are briefly dealt with.

**Shoeing and balancing the light harness horse**, J. CLARK (*Buffalo, N. Y.: The Horse World Co., 1916, pp. 101, pl. 1, figs. 50*).—A small handbook.

**The epidemiology of pectoral influenza of the horse**, K. MACEK (*Wiener Tierärztl. Monatsschr., 2 (1915), No. 12, pp. 553-567; abs. in Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 6, pp. 848, 849*).—The author first refers to the work of Gaffky and Lührs, previously noted (*E. S. R., 31, p. 382*), and then reports studies made of 76 of 380 horses in a large stable that were affected with pectoral influenza (Brustseuche). His investigations led to the following conclusions:

"The incubation stage of pectoral influenza is much longer than has been generally supposed. In working horses it is from three to four weeks, while in resting horses twice this period may elapse before the outbreak of visible signs of the disease. This may account for outbreaks caused by bringing horses, quarantined for four weeks, into contact with healthy horses. Generally, during a four weeks' quarantine, the disease will make itself manifest. An infected horse can infect another horse not alone when distinct clinical symptoms of influenza are present, but also in the incubation stage, while it still appears to be in good health, and especially in the last few days preceding the outbreak of the disease.

"The spread of influenza may be checked with certainty if the first cases are recognized and promptly isolated, thus preventing contact between infected and noninfected horses. The isolation stall need not be far from the others and may even be among them so long as healthy animals are not exposed by contact. The direct transmission of influenza from horse to horse is the principal way in which it spreads. In this connection the stall, as well as various intermediate carriers (i. e., attendants, dirt, straw, feed, rats, mice, sparrows, blankets, harness, pails, etc.), play an unimportant rôle. Apparently the causative agent of influenza soon dies outside of the body of the horse.

"The spread of influenza from place to place is to be explained according to the previously made observations, i. e., that horses having a long incubation period transmitted the infection to other horses with which they had come in contact.

"Convalescent, symptomatically treated horses should not be permitted to come in contact with healthy ones until four weeks after the fever has subsided. However, animals in which the fever subsides in 36 to 48 hours after treatment with neosalvarsan may be released eight days after its drop to normal."

In most cases the author found a single infusion of 4.5 gm. of neosalvarsan to reduce the fever to normal within 24 to 36 hours.

**A tri-radiate tapeworm (*Anoplocephala perfoliata*) from the horse, F. J. MEGGITT (*Parasitology*, 8 (1916), No. 4, pp. 379-389, pl. 1, figs. 2).**—A report of anatomical studies made of a tri-radiate form of tapeworm taken from a horse which had died from the cumulative effects of numerous parasites.

**Diseases of the dog and their treatment, G. MÜLLER and A. GLASS (*Chicago: Alexander Eger, 1916, 4. ed., rev. and enl., pp. 506, pls. 17, figs. 178; rev. in Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 6, p. 881*).**—A fourth revised and enlarged edition of the work previously noted (E. S. R., 21, p. 684).

**Parasitological investigations (*Kansas Sta. Rpt. 1915, p. 20*).**—Investigations have confirmed the report previously noted (E. S. R., 30, p. 485) that the fowl nematode (*Heterakis perspicillum*) may be transmitted by the dung earthworm (*Helodrilus parvis*), but indicate that the transmission is due to association rather than parasitism. It was found that cottontails and jack rabbits infested with tapeworm cysts may be fed to fowls without danger of transmitting the tapeworms.

## RURAL ENGINEERING.

**Annual report of the state engineer and surveyor of the State of New York, 1914 (*Ann. Rpt. State Engin. and Surveyor N. Y., 1914, pp. 448, pls. 64*).**—This reports the activities and expenditures of the office of the New York State engineer and surveyor for the fiscal year ended September 30, 1914.

**The action of copper sulphate on the algæ in drinking water, A. A. BADO (*La Acción del Sulfato de Cobre sobre las Algas de las Aguas Potables. Buenos Aires: Govt., 1916, pp. 15, pls. 4*).**—Experiments on the treatment of La Plata River water with copper sulphate to destroy algæ are reported.

It was found that for that water the optimum amount of copper sulphate for algæ destruction is 2 parts per million, used at intervals of from five to ten days. It was further found that the coli bacteria were not entirely removed from the water by such treatment.

**Chlorin treatment of water, R. HILSCHER (*Cal. Bd. Health Mo. Bul., 12 (1916), No. 2, pp. 84-86, fig. 1; West. Engin., 7 (1916), No. 10, pp. 382, 383, fig. 1*).**—A simple hypochlorite plant for treating water is illustrated and described, and the hypochlorite treatment is briefly compared with the liquid chlorin treatment.

**Successful sewage disposal by broad irrigation, T. BARTLETT (*Engin. News, 76 (1916), No. 13, pp. 586, 587, figs. 5*).**—This article states that an average daily flow of sewage of about 13,500,000 gal. from San Antonio, Texas, is delivered to an irrigation company through the agency of which some 1,600 acres of private land are irrigated. A natural lake enlarged for the purpose is used to store the sewage when not needed for irrigation.

"The present annual quantity of sewage received from the city's trunk outlet is roughly estimated at 15,000 acre-feet. Of this some 8,000 acre-feet are applied to the lands by broad irrigation at an estimated average daily rate of 10,000 gal. per acre during the season. The remainder is impounded in the lake, together with from 400 to 800 acre-feet of storm water. From a small marshy flat the lake has been extended by successive increases in the height of

the dam, until it now covers some 900 acres to an average depth of from 8 to 10 ft. . . .

"The results of the disposal from the standpoint of avoidance of nuisance are extremely successful. . . . The broad, shallow lake, with partial dilution and abundant opportunity for sedimentation and oxidation, effects a high degree of purification, and there is no odor from it except a slight marshy smell."

**Disposal of sewage from country houses, small institutions, and country clubs,** P. HANSEN (*Ill. Health News, n. ser., 2 (1916), No. 8, pp. 151-167, figs. 11*).—This article deals with sanitary privies; chemical closets; sewage tanks, including Imhoff tanks; and purification systems, including tile absorption areas, intermittent sand filters, contact filters, and sprinkling filters.

**Double tank proposed for residential sewage plants,** W. S. COULTER (*Engin. Rec., 74 (1916), No. 10, pp. 298, 299, figs. 2*).—The author maintains that the logical arrangement for residential sewage-disposal plants is a septic tank and a short-period Imhoff tank placed in series. "The two-story tank then serves to intercept matter carried over from the septic tank and, if given reasonable attention, should insure a well clarified effluent. The Imhoff tank should be provided with light, strong checkered plate covers to allow unobstructed access to the slopes and gas vent. . . . The upward-flow type possesses advantages peculiarly fitting it for the primary tank in such a series, the influent being admitted at a point near the bottom and caused to pass upward through the sludge accumulation."

The greenhouse type of sludge drying bed and a ventilating duct for aerating the tile fields are advocated.

**Conveyance of water in open channels on the farm** (*Jour. Electricity, 37 (1916), No. 14, pp. 261-263, figs. 4*).—Curves are given showing the carrying capacity of small earth ditches varying in area of water cross-section from 0.5 to 8 sq. ft. and in fall from 0.25 to 10 ft. per 1,000-ft. length, the capacity being expressed in miner's inches, second-feet, and gallons per minute.

**Surface water supply of North Atlantic slope drainage basins, 1914,** (*U. S. Geol. Survey, Water-Supply Paper 381 (1916), pp. 195+XXXVII, pls. 2*).—This report, prepared in cooperation with the States of Maine, Vermont, Massachusetts, and New York, presents the results of measurements of flow made on the St. John, St. Croix, Machias, Union, Penobscot, St. George, Kennebec, Androscoggin, Presumpscot, Saco, Merrimack, Connecticut, Housatonic, Hudson, Delaware, Susquehanna, Patuxent, Potomac, and Rappahannock river basins during 1914. Lists of the stream-gaging stations and the publications of the Geological Survey relating to water resources for this region are appended.

**Supplement to the annual report of the state engineer and surveyor of the State of New York, 1914** (*Ann. Rpt. State Engin. and Surveyor N. Y., Sup., 1914, pp. 367*).—This report presents the results of measurements of flow made on streams in New York during 1914.

**Oregon's opportunity in national preparedness,** J. H. LEWIS, L. F. HARZA, G. STUBBLEFIELD, and E. J. MCCAUSTLAND (*Off. State Engin. Oreg. Bul. 5 (1916), pp. 120, figs. 28*).—This bulletin presents tentative plans and estimates of cost for the construction of a number of large water-power projects in Oregon, discusses possibilities for marketing some of this power, and points out direct and indirect benefits of such work, with special reference to the manufacture of nitrates, munitions of war, and fertilizers.

**Rainfall and agricultural power use,** S. B. SHAW (*Jour. Electricity, 37 (1916), No. 13, pp. 242, 243, figs. 4*).—The results of studies made in the Santa Clara Valley, Cal., on the effect of the amount of rainfall and of its distribution throughout the season upon the consumption of electric energy by irrigation plants are graphically reported.

It was found that "the amount of rain falling in a certain season influences the agricultural load in the succeeding months; thus when there is a season of heavy rainfall it is followed by a season of proportionally light irrigation and, therefore, of poor load factor on pumping plants, and vice versa. The time at which the rainfall occurs is also of importance. Thus, early fall rains during the months of September, October, and November will cause a rapid decrease in the pumping load at that time, while the late spring rains in March, April, and May will similarly delay the rise of the spring peak, both of which result in a decreased load factor and decreased total consumption. A concentration of the precipitation during the months of December, January, and February results in less penetration and replenishment of ground water and a greater run-off. This will result in an increase in the total annual consumption and load factor."

The normal average power consumption for the locality was found to be about 435 kilowatt hours per horsepower of plant capacity per annum.

Description of water wheel at Kudarangan Agricultural School, A. E. HALEY ([*Philippine Bur. Pub. Works Quart. Bul.*, 5 (1916), No. 1, pp. 22, 23, fig. 1; *abs. in Engin. News*, 76 (1916), No. 9, pp. 409, 410, fig. 1).—A water wheel for irrigation in the Philippine Islands is described and diagrammatically illustrated.

"Measurements of the wheel show that it raises about 25 gal. per minute, or 40,000 gal. per day, while operating in water flowing three miles per hour. Each bucket carries 4 gal. of water and the wheel makes a complete revolution in 70 seconds. The water raised is sufficient to irrigate about 1.5 hectares [3.7 acres] of ground."

A complete method for the classification of irrigable lands, F. H. PETERS (*Proc. Amer. Soc. Civ. Engin.*, 42 (1916), No. 7, pp. 1231-1251, pl. 1, figs. 7).—This paper deals with the classification by the Dominion Government of an area of about 1,037,000 acres of irrigable land developed in the Province of Alberta. The climatic, soil, and crop conditions of the area are described and, as governed by these, the basis of the classification is stated as follows:

"Land shall be classified as irrigable (1) if it lies at a lower elevation than the point of delivery, after allowing a reasonable grade for a farm lateral. The point of delivery shall be deemed to be a point 3 in. below the crest of the measuring weir at or within the farm boundary. Where this measuring weir is not at or within the farm boundary, the point of delivery shall be the elevation of full supply level in the lateral supplying the field outlet and all measuring weirs shall be built in accordance with the plan of farm weirs filed with the commissioner of irrigation and dated November 1, 1908. The grade of farm laterals when a factor in land classification will be considered reasonable, (a) where the natural slope of the ground is less than 0.1 ft. in 100 ft. at a rate not less than 0.05 ft. in 100 ft.; (b) where the natural slope of the ground is greater than 0.1 ft. in 100 ft. at a rate of not less than 0.1 ft. in 100 ft.; and (c) where the slope of the ground is at or near the critical slope of 0.1 ft. in 100 ft. at either of the grades mentioned in clauses (a) and (b), such as good and reasonable practice demands. Extremely flat country may be irrigated by checks and flooding, and the grade of the farm lateral need not be considered in such cases, it being understood that the minister of the interior, or officers appointed by him, shall be the final judges of what constitutes 'extremely flat country.'

"(2) If such land can be reached by an estimated concentrated expenditure at one or more points for embankments, flumes, etc., not in excess of \$8 per acre for the land to be served and benefited through them. (3) If such land

can be served by a second or other delivery at a cost not in excess of \$8 per acre for the land to be served and benefited through them. (4) When lying in a depression, if it can be drained at a cost not exceeding \$8 per acre and is suitable arable land which would be benefited by irrigation.

"(5) The prices to be made use of in estimating the cost of embankments, flumes, or other structures shall be, unless otherwise ordered by the Minister of the Interior [as follows]: Earth fill or excavation, 12 cts. per cubic yard; lumber in place on any structure, \$40 per 1,000 ft. board measure; and rock riprap, 50 cts. per superficial yard.

"(6) In all unusual or exceptional cases, which are not covered by the preceding paragraphs, the classification will be made by officers of the department, under the direction of the minister of the interior, in a fair and reasonable manner, and will be based on the beneficial use of water."

**Official proceedings of the sixth annual meeting of the National Drainage Congress at Cairo, Illinois** (*Off. Proc. Nat. Drainage Cong.*, 6 (1916), pp. 96).—These proceedings include the following special articles:

Federal Legislation, by F. H. Newell; The Relation of Drainage and Flood Control, by A. L. Webster; The Ohio Conservancy Act and State Legislation, by E. F. Bohm; Farm Drainage, by J. T. Stewart; Flood Prevention in the Miami Valley, by S. M. Woodward; Benefits from the Regulation of the Missouri River, by C. E. Jacoby; Reclamation and Flood Control in California, by V. S. McClatchy (see below); Food Protection in Indiana, by W. K. Hatt; Drainage Construction Problems, by W. A. O'Brien; Improving the Mississippi to Aid Commerce and Drainage, by T. H. Farmer; Relation of Land Drainage to Improvement of Rivers for Navigation, by J. L. Van Ornum; Organization Expenses and How to Meet Them, by R. B. Oliver, jr.; Work of the Illinois Rivers and Lakes Commission, by L. K. Sherman; The Drainage Situation in Oregon, by W. L. Powers.

**Flood control and reclamation in California**, V. S. McCLATCHY ([*Sacramento*], Cal.: State, 1916, pp. 8, pl. 1; *abs. in Off. Proc. Nat. Drainage Cong.*, 6 (1916), pp. 69, 70).—This pamphlet briefly describes the different flood control problems in California, and includes a map showing the Sacramento River flood control project.

**Reclamation of the Worden tract**, D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1915, pp. 22-24, fig. 1*).—Drainage of a heavy alkali soil in which the water table stood at a depth of only 0.77 ft. lowered the ground-water table to a depth of 6 ft.

**The experiment farm drainage system**, F. B. HEADLEY (*U. S. Dept. Agr., Bur. Plant Indus., Work Truckee-Carson Expt. Farm, 1915, pp. 12-14*).—Estimates of the total amounts of salts removed in the drainage water in the experimental drain on the project show that the largest amount of salt is removed during the irrigation season.

"A total of 214 tons of alkali has been removed by this drainage system in three years, approximately 8.5 tons for each acre of the area drained. The amount of salt in the upper 3 ft. of this portion of the farm amounts to approximately 9 tons per acre, or about the same amount as has been removed in three years by the drainage system. The soil of the area served by the drainage system does not show any appreciable reduction of its salt content in the upper 3 ft. It would appear, therefore, that the tile-drainage system draws alkali water either from sources deeper than the surface 3 ft. of soil or from an area much larger than the actual extent of the system. Beneficial results, as indicated by the improvement of crops, do not seem to have been obtained as yet from the installation of this system of drainage, although it

may have prevented a general rise of the ground water that would have been of serious consequence."

Some suggestions for the organization and financing of drainage projects, S. H. McCROBY (*Agr. of Mass.*, 63 (1915), pp. 103-115).—The author outlines briefly some of the fundamental principles governing the organization and financing of drainage districts. "Those who may be charged with the preparation of a law on drainage should make a careful, comprehensive study of the needs of the State, and of the laws of other States which have proved successful. Too much caution can not be exercised in drafting such a law so that it may be in harmony with the state and Federal constitutions and the trend of decisions on the subject."

Proceedings of the second Good Roads Institute, held at the University of North Carolina, February 23-27, 1915, compiled by J. H. PRATT and MISS H. M. BERRY (*N. C. Geol. and Econ. Survey, Econ. Paper 43* (1916), pp. 122, figs. 7).—These proceedings contain the following special articles: Considerations Governing the Proper Locations of Roads, by T. F. Hickerson; Economical Methods of Moving Rock, by W. S. Fallis; The effect of Grades Upon the Design and Location of Roads, by D. T. Brown; Economical Methods of Moving Earth in Road Construction, by N. C. Hughes, jr.; Sand-clay, Topsoil, and Gravel Roads, by C. M. Strahan; Sand-clay and Topsoil Roads in Craven and Wayne Counties, by R. E. Snowden; Sand-clay and Topsoil Roads in Orange County, by R. T. Brown; Use of Bituminous Compounds in Road Construction, by F. M. Whitfield; Specifications: A Discussion of Their Importance in Road Building, by B. S. Drane; and Road Maintenance, by W. W. Crosby.

[Road laws of the State of Kentucky] (*Ky. Dept. Pub. Roads Bul. 6* (1916), pp. 116).—This is a compilation of the laws of Kentucky relating to public roads and their management.

Economic surveys of county highway improvement, J. E. PENNYBACKER and M. O. ELDRIDGE (*U. S. Dept. Agr. Bul. 393* (1916), pp. 86, pls. 36).—This is a compilation and analysis of data obtained in eight selected counties, Spotsylvania, Dinwiddie, Lee, and Wise counties in Virginia, Franklin County in New York, Dallas County in Alabama, Lauderdale County in Mississippi, and Manatee County in Florida, showing comparative financial burdens and economic benefits resulting from highway improvement during the period from 1910 to 1915, inclusive. On the whole the experience of the eight counties demonstrated that "the beneficial effects of the road improvement justified the outlay, and that while more efficiency and economy might have been obtained in some cases, the loss was not such as to make the citizens of any of the counties feel that the move for better roads had been an unwise one."

With reference to the increase in the values of farm lands it was found "that following the improvement of the main market roads the increase in the selling price of tillable farm lands served by the roads amounted to from one to three times the total cost of the improvements. The increases in values in those instances which were recorded ranged from 63 per cent to 80 per cent in Spotsylvania, from 68 to 194 in Dinwiddie, 70 to 80 in Lee, 25 to 100 in Wise, 9 to 114 in Franklin, 50 to 100 in Dallas, 25 to 50 in Lauderdale, and from 50 to 100 in Manatee." Considering the eight counties in the aggregate, the gross annual savings in hauling costs due to their good-roads systems amounted to a total of \$627,409 for a traffic of 3,489,652 ton-miles. The average gross saving per ton-mile for the eight counties was 17.8 cts., this being indicated by an average rate of 33.5 cts. before the roads were improved, as compared with 15.7 cts. after the roads were improved. The net saving per ton-mile after deducting the cost of the interest and principal was 11.6 cts.

A comparison of the effect of the road improvement upon country schools showed that before the roads were improved the average school attendance was 66 pupils of each 100 enrolled, as compared with 76 after the roads were improved, showing that the good roads have been materially responsible for the education of 10 children out of each hundred.

**Bituminous macadam and bituminous concrete pavements**, A. H. BLANCHARD (*Municipal Jour.*, 41 (1916), No. 14, pp. 405-411, figs. 9).—This article summarizes the more recent opinions of authorities on the materials and methods requisite for the most successful construction and maintenance.

**In monolithic pavements in Vermilion County, Illinois, brick are laid directly on concrete base**, H. H. EDWARDS (*Engin. Rec.*, 74 (1916), No. 14, pp. 400-402, figs. 7).—This article summarizes experience in which the thin layer of dry sand and cement was discarded. The brick were grouted immediately after rolling.

**Distribution of traffic on a rectangular system of roads analyzed**, E. W. JAMES (*Engin. Rec.*, 74 (1916), No. 15, pp. 439-441, figs. 2).—Tabular data are reported which show the relative travel on various types of roads where the development is uniform throughout a township and where it is unequal and more in accordance with ordinary experience. It is pointed out that from 80 to 85 per cent of all traffic in any large area is carried by 15 or 20 per cent of the roads and that expenditures should be governed accordingly.

**Progress reports of experiments in dust prevention and road preservation, 1915** (*U. S. Dept. Agr. Bul.* 407 (1916), pp. 71).—New experiments begun by the Office of Public Roads and Rural Engineering during the year 1915 are described. These included experiments on bituminous macadam (penetration and mixing methods) and bituminous gravel concrete on Mount Vernon Avenue road, Alexandria County, Va.; bituminous surface treatment on Falls Road, Montgomery County, Md.; penetration macadam on Bradley Lane, Montgomery County, Md.; bituminous concrete at Washington, D. C.; oil-asphalt-coralline rock at Buena Vista, Fla.; oil-asphalt-sand at Jupiter, Palm Beach County, Fla.; bituminous-sand, mixing methods at West Palm Beach, Fla.; and sand-asphalt at Ocala, Fla.

Supplementary reports on experiments previously reported (*E. S. R.*, 33, p. 686) are included on oils, tar preparation, calcium chlorid-coralline rock at Lemon City, Fla.; oil, tar, oil-asphalt-coralline rock at West Palm Beach, Fla.; oil-coralline rock at Miami, Fla.; bituminous surface treatment on Rockville Pike, Montgomery County, Md.; tar preparation and oil-surface treatment at Washington, D. C.; bituminous concrete, cement concrete, oil-cement concrete, vitrified brick, bituminous surface treatment on concrete and bituminous construction and surface treatment at Chevy Chase, Md.; oil-cement concrete, oil asphalt, tar and fluxed native asphalt at Jamaica, N. Y.; oil-asphalt-gravel at Ames, Iowa; tar and oil preparations at Knoxville, Tenn., 1910; slag, lime, waste sulphite liquor and tar at Youngstown, Ohio; sand-clay at Dodge City, Garden City, Bucklin, and Ford, Kans.; and Kentucky rock asphalt at Bowling Green, Ky.

**Road dust preventives: References to books and magazine articles** (*Pittsburgh, Pa.: Carnegie Library, 1916, pp. 39*).—A list of 361 references to books and magazine articles bearing on the subject is given.

**Concrete construction for rural communities**, R. A. SEATON (*New York and London: McGraw-Hill Book Co., 1916, pp. XI+223, pl. 1, figs. 96*).—This is a semitechnical treatise on the essential features of concrete construction on farms and in rural communities. It is divided into five parts. Part 1, Materials, deals with cements and limes, cement specifications and tests, and aggre-

gates; part 2, Plain Concrete, deals with proportions and quantities of materials, construction of forms, and mixing and handling concrete; part 3, Reinforced Concrete, deals with general principles and strength of reinforced concrete; part 4, Miscellaneous Matters, deals with concrete surface finishes, stucco and plaster work, waterproofing and coloring concrete, and casting in molds; and part 5, Typical Applications of Concrete, deals with sidewalks, floors, and roads; tanks, cisterns, and silos; and small highway bridges and culverts.

**Official tests of mechanical cultivation** (*Jour. Agr. Prat., n. ser., 29 (1916), No. 13, pp. 230-232, figs. 2*).—Tests on the cultivation of very light sandy soil with a 16-horsepower and a 25-horsepower tractor are reported. The former weighed 2,800 kg. (about 3 tons) and had a horizontal single-cylinder motor running at about 400 revolutions per minute. The latter weighed 4,700 kg. and had a horizontal two-cylinder opposed motor running at about 550 revolutions per minute. The test results are given in the following table:

*Mechanical cultivation tests.*

Type of cultivator.	Tractor, horse-power.	Depth of cultivation.	Width of cultivation.	Average speed per hour.	Area cultivated per hour.	Fuel consumption.	
						Per hour.	Per hectare.
		<i>Centi-meters.</i>	<i>Meters.</i>	<i>Meters.</i>	<i>Square meters.</i>	<i>Kilo-grams.</i>	<i>Kilo-grams.</i>
3-bottom plow .....	16	16.0	0.97	3,276	2,325	5.66	24.3
4-bottom plow .....	25	20.9	1.26	2,736	2,460	6.72	27.3
12-tooth cultivator, soil plowed one week .....	16	6.5	2.00	3,348	4,762	4.43	9.3
12-tooth cultivator, soil recently plowed .....	16	11.0	2.00	3,348	4,762	4.84	10.1
12-tooth cultivator on fallow .....	16	7.0	2.00	3,348	4,762	4.02	8.2
14-disk harrow on fallow .....	16	4.0	2.10	3,348	5,000	4.06	8.1
14-disk harrow, soil recently plowed .....	16	10.0	2.10	3,276	4,958	5.22	10.5

**Official tests of mechanical cultivation** (*Jour. Agr. Prat., n. ser., 29 (1916), No. 15, pp. 262-264, figs. 2*).—Tests of a 3-wheeled tractor with a 4-cylinder vertical motor rated at 20 horsepower in plowing, rolling, and harrowing on a heavy clay soil are reported. The two front wheels, 0.62 meter (24.4 in.) in diameter, are guide wheels and the rear wheel, 1.52 meters in diameter, is a driver. The total weight of the tractor is 2,800 kg. (about 3 tons). The test results are given in the following table:

*Mechanical cultivation tests.*

Cultivating apparatus.	Depth of cultivation.	Width of cultivation.	Area cultivated per hour.	Fuel consumption.		Average speed per hour.
				Per hour.	Per hectare.	
	<i>Centi-meters.</i>	<i>Meters.</i>	<i>Square meters.</i>	<i>Kilograms.</i>	<i>Kilograms.</i>	<i>Meters.</i>
2-bottom plow .....	15.7	0.61	2,083	8.60	41.2	5,292
Do. ....	22.7	.58	1,087	5.40	49.6	2,592
4-bottom plow .....	17.5	1.00	1,887	5.50	29.1	2,772
3-bottom plow .....	15.0	.94	2,421	6.90	28.5	3,600
Do. ....	20.4	.91	2,364	7.26	30.7	3,492
Do. ....	13.0	.94	1,886	7.86	40.9	2,772
Do. ....	18.0	.88	1,744	8.51	49.0	2,700
13-tooth cultivator .....	10.0	1.56	3,333	6.32	18.9	2,988
13-tooth cultivator and roller .....	10.0	1.56	3,225	7.59	23.5	2,880
48-tooth harrow on plowed soil .....	4.5	2.00	6,900	8.22	11.9	5,400
13-tooth cultivator on fallow soil .....	10.0	1.56	3,186	6.27	19.8	2,808

**Dairy barn construction**, L. A. HIGGINS and D. SCOATES (*Miss. Agr. Col. Ext. Dept. Bul. 2*, pp. 8, figs. 7).—This bulletin points out the essential features in dairy-barn construction, and gives diagrammatic illustrations of the more important details in construction.

**Building instructions for homemade silos**, G. L. OLIVER (*West Virginia Sta. Bul. 157 (1916)*, pp. 14-23, figs. 8).—This is a revision of Circular 8, on the construction of wooden hoop silos (E. S. R., 32, p. 888), with additional information, prepared in cooperation with the U. S. Department of Agriculture, on the building of stave and plastered silos.

**Poultry houses**, E. J. PETERSON (*North Dakota Sta. Circ. 14 (1916)*, pp. 4, figs. 4).—The general requirements of poultry house construction to meet North Dakota conditions are outlined.

**A farmer's poultry house**, J. G. HALPIN and L. M. SCHINDLER (*Wis. Col. Agr. Ext. Serv. Circ. 62 (1916)*, pp. 4, figs. 2).—Plans and a bill of materials for a poultry house to accommodate 125 hens are given.

**A dual-purpose poultry house**, J. HADLINGTON (*Agr. Gaz. N. S. Wales, 27 (1916)*, No. 9, pp. 656-659, pl. 1, figs. 2).—Plans and brief specifications for a poultry house to serve as a brooder and laying house are given.

## RURAL ECONOMICS.

**Successful farm organizations**, O. R. JOHNSON (*Missouri Sta. Bul. 142 (1916)*, No. 9, pp. 656-659, pl. 1, figs. 2).—Plans and brief specifications for a already noted in Bulletins 121 and 140 (E. S. R., 32, p. 791; 35, p. 692).

The author, in summarizing the results of this survey, indicates that about 40 per cent of the farmers in the regions studied made less than \$200 labor income, and about 70 per cent made less than \$600. The average labor income was about \$1.35 per day. The most successful farmers had farms larger than 200 acres.

The least successful farmers had 7 per cent more of their capital invested in real estate than did the most successful farmers. This difference in capital was chiefly invested in live stock in case of the better class of farmers. On the more successful farms the workmen handled from 60 to 100 per cent more crop acres than did the workmen on the less successful farms. The better farmers kept more live stock and a larger proportion of this stock was in productive stock and less in work stock. The less efficient farmers received from \$17 to \$25 per animal unit while the better farmers received from \$37 to \$47.

Sixty-eight per cent of the best farms had more than three important sources of income. The crop yield index on the best farms was 124.8 and on the poorest farms 86.8. The farmers realizing the better incomes used one-fifth less feed for each animal unit kept, but realized four times as much in return for each \$100 worth of feed used.

**Farming on the cut-over lands of Michigan, Wisconsin, and Minnesota**, J. C. McDOWELL and W. B. WALKER (*U. S. Dept. Agr. Bul. 425 (1916)*, pp. 24, figs. 10).—Among the conclusions set forth by the authors from their study of conditions on 801 typical farms in this area and an investigation of farm enterprises on 80 farms, were the following:

With average yield and average price, potatoes furnish a satisfactory cash crop in practically all parts of the district. Large acreage, however, is not to be generally recommended on account of the danger of low prices resulting from local overproduction. Other valuable cash crops adapted to certain areas are hay, clover seed, peas, beans, hairy vetch, seed corn, oats, rye, wheat, barley, small fruit, and garden vegetables.

As there are few large cities, the demand for truck crops is somewhat limited in most parts of the district. The well-managed farms produce an abundance of home supplies, such as vegetables, small fruit, milk, butter, eggs, and meat.

Dairying combined with cash crops is financially profitable when production per cow is high and crop yields above the average. The production of sheep or beef cattle as a major enterprise, while not common in the district, is furnishing satisfactory incomes on a few farms. Hog production may be profitably combined with dairying where corn matures and on farms where rye, barley, soy beans, or Canadian field peas can be substituted for corn.

On account of the opportunity to use extra labor to advantage at all seasons of the year, either in lumbering or in clearing land, seasonal distribution of farm labor has not yet become an important problem in recently settled sections. A large amount of family labor is available, much of which is not used to advantage. The crop area per horse is too small for the most profitable use of labor. Small irregular fields and numerous stumps prevent the most efficient use of farm machinery. Few farmers in this district are rapidly accumulating wealth, but, with ceremony and good management, there is an opportunity to make a living and a little more.

**Management of muck-land farms in northern Indiana and southern Michigan.** H. R. SMALLEY (*U. S. Dept. Agr., Farmers' Bul. 761 (1916), pp. 26, figs. 12*).—Four distinct types of farms were found among the muck lands, namely, celery, onion, peppermint, and grain and stock farms.

Among the conclusions drawn by the author were that the use of fertilizer, especially potash, on muck soils is very profitable, the yields being increased in most cases from 50 to 200 per cent.

Celery and onions require an enormous amount of man labor as compared with corn, oats, and hay. Peppermint, cabbage, and potatoes occupy an intermediate position. The gross acre value of the intensive crops is high, but the value of these crops per day of man labor is not so high as in the case of the extensive crops. The average labor income for 28 celery farms was \$394; for 23 onion farms, \$1,732; for 10 peppermint farms, \$1,519; for 39 grain and stock farms, \$1,056; and for 7 of the more successful grain and stock farms, \$1,994. The grain and stock farms provide a much better distribution of labor throughout the year than the other types and are deemed a much safer type of farming, although the profits per acre may be less.

**Cost accounts on some New York farms.** C. E. LADD (*New York Cornell Sta. Bul. 377 (1916), pp. 771-815, figs. 3*).—This bulletin gives the results obtained from keeping a complete set of cost accounts on 13 New York farms for 1912 and 31 for 1913. It contains a large number of statistical tables, showing the hours of labor for man and horse and the cost per hour and per acre. It also gives the cost per acre and per horse for equipment, the extent, value, cost, and profit of various farm crops, live stock, and the monthly distribution of labor by enterprises and operations in connection with the individual enterprises.

**Cotton ginning information for farmers.** F. TAYLOR, D. C. GRIFFITH, and C. E. ATKINSON (*U. S. Dept. Agr., Farmers' Bul. 764 (1916), pp. 24, figs. 25*).—The authors conclude that the present mechanical construction of gins makes it almost impossible for them to maintain the purity of each grower's seed on account of the added expense to the ginner in bringing about such conditions as will insure the accurate separation of seed which is to be used for planting purposes from the seed of other varieties of cotton. They consider it desirable that gin manufacturers develop some device which will insure a quick and ac-

curate method of keeping separate the seed ginned from each wagon load of seed cotton. They also discuss the methods of keeping accounts and the arrangement and use of ginning machines to bring about a better marketing condition for the cotton. Attention is called to the careless preparation of the American bale of cotton and the seeming indifference on the part of the farmer, the buyer, and others handling the American bale which causes the farmer a considerable loss. "By concerted action the farmers should be able to secure better methods of ginning, maintain pure planting seed, and secure uniform and better handling of their cotton. This would enable them to market their crops to a better advantage."

**Community organization for promoting the production of swine, C. G. STARR** (*Indiana Sta. Circ. 54* (1916), pp. 12, figs. 2).—In addition to a brief discussion on the improving of swine production by better feeding, breeding, and management, the author discusses the control of hog cholera by community effort and points out how hog cholera is spread and how the community can be organized to control this disease. There is included a proposed plan of community organization and a model constitution and by-laws.

[Studies in agricultural economics] **A. E. CANCE** (*Massachusetts Sta. Rpt. 1915, pt. 1, pp. 69a, 70a*).—There are two main types of agricultural insurance practiced in the New England States—live stock insurance, which is confined mainly to insurance on race-horse stock and exhibit stock when shipped to shows, and hail insurance of tobacco against damage by hail. Brief notes are given regarding these.

A study of the methods and cost of growing and distributing onions in the Connecticut Valley indicates that the cost of production and marketing is from 36.6 to 40.6 cents per bushel.

**A survey of typical cooperative stores in the United States, J. A. BEXELL, H. MACPIERSON, and W. H. KERR** (*U. S. Dept. Agr. Bul. 394* (1916), pp. 32, pls. 2).—Data collected from 60 stores in 10 states by the Office of Markets and Rural Organization in cooperation with the Oregon Agricultural College are reported and discussed.

"The figures collected in this survey bring out the conclusion that the majority of the cooperative stores established are unsuccessful in achieving their main object—saving on purchases to members and a reduction of the high cost of living. This conclusion is borne out by the supplementary notes collected from managers who could not apply statistics, and by notes on interviews with leaders who are acquainted with the store movement in whole sections which could not be covered in detail. But that there is one real service which the cooperative stores have performed seems to have been demonstrated again and again. Even in cases where stores have failed absolutely and gone into bankruptcy they have frequently been responsible for the introduction of improved business methods in the towns where they were established. They have had the effect of stimulating competition. In cases where the merchants have competed keenly against the cooperative store they have been compelled to adopt more efficient business methods. This has resulted in lower prices to every consumer in the locality and frequently in better prices to farmers on produce."

The authors believe that the conditions necessary for success are good leadership, capable management, favorable environment, and adequate legal safeguards, and that a lack of these generally is the cause of failure. Throughout the bulletin are included a number of statistical tables setting forth the various facts concerning the stores from which this survey was made.

**Rural clubs in Wisconsin, C. J. GALPIN and D. W. SAWTELLE** (*Wisconsin Sta. Bul. 271* (1916), pp. 58, figs. 22).—The authors believe that living on good terms with folks is a part of modern farming, as truly as knowing how to farm,

and that the higher level of efficiency is reached in the science and art of local agriculture when families know one another well and meet frequently. A strong circulation of ideas and impulses is deemed necessary to counteract discontent and the temptation to sell out and move away from rural districts.

The authors state that about one-fifth of the farmers in Wisconsin are members of or attend the meetings of various rural clubs. They have divided the rural clubs into four typical groups and describe typical instances to illustrate the types. The four types mentioned are the farmers' family club, the farm men's club, the farm women's club, and the young folks' club.

**Monthly crop report** (*U. S. Dept. Agr., Mo. Crop Rpt., 2 (1916), No. 10, pp. 97-108, figs. 3*).—Among the data included in this report are the usual data relative to the condition of the principal crops, their estimated farm values, and the range of prices of agricultural products at important markets. Special reports are included concerning the commercial production of cabbage, cucumbers, the monthly disposition of cotton by producers, the quantity of commercial fertilizer applied per acre of cotton, the trend of prices paid producers, wheat statistics for the world and the United States, and the estimated production of apples by States from 1890 to 1915. A special map is also included showing the location of the township crop reporters.

### AGRICULTURAL EDUCATION.

**Agricultural education**, H. J. WATERS (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 193-199*).—The author discusses the principal purpose of agricultural education, the tax of wastes upon the cost of living, high acre yields and low man yields, what city people and country children should be taught, and where agriculture should be taught.

In his opinion city children should not be required to study the details of plant and animal production, but should be so taught that they will have an interest in, and a general understanding of, these basic industries, so that they will realize that they are dependent upon those who till the soil, not only for their food and clothing, but also for the materials which form the basis of most of the city's industries. On the other hand, country children should be taught how to produce high-acre yields without bringing upon themselves the evils of the intensive methods of other countries and of other times.

The failure of early attempts to teach agriculture is attributed principally to the fact that the farmer himself knew more about farm practice than did the teacher. This led to the establishment of agricultural experiment stations, a deliberate attempt, for the first time in the history of education, to create, through a well coordinated system of scientific research, a body of knowledge in relation to a subject which it was deemed important to teach but about which so little of a definite nature was known that it could not be taught successfully. Attention is also called to another important departure from educational traditions, viz, an organized system of extension or continuation teaching through which parents as well as pupils are reached with new-found knowledge.

The author concludes that "income and idealism are the principal elements out of which a stable and satisfactory rural civilization will be built. To build such a civilization is the only possible excuse we can offer for devising and maintaining a system of agricultural education."

**Progress of elementary agricultural education in Nova Scotia**, L. A. DEWOLFE (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 520-522*).—According to this article school gardening and nature study are making about the

same progress in Nova Scotia as in this country. The school garden has not proved a success because of the vacation problem, but children's gardens on the home grounds have proved popular and school exhibitions are a prominent feature of the work each autumn. More stress is laid on flower culture than on vegetable culture, as the same cultural principles belong to both and the flowers are more interesting.

The teachers, who are the leaders in this work, take a special training course for two or three summers at Truro, these courses being conducted jointly by the normal and agricultural colleges and leading to a rural science diploma. Teachers receive a small additional salary grant, \$25 or \$50, for rural science work.

**The efficient country school, D. B. JOHNSON** (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 683-687*).—The author discusses the vital need in this country of the efficient country school, with its equipment, curriculum, and teacher.

**Applied science as the basis of the girl's education, HAZEL W. SEVERY** (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 1020, 1021*).—In this article science courses to meet the general needs of all girls are classified under two heads: (1) Courses for girls who are planning a scientific or technical education, and (2) courses which make better homes because the sciences are taught in a simple but practical way. The latter are discussed, including a consideration of what they should consist and a few of their possibilities.

**Special science for girls in the rural schools, BLANCHE O. TWISS** (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 1015-1019*).—The author emphasizes the need of the teaching of sciences for both boys and girls, and of well-grounded, finely trained women of broad experience to conduct this work in rural communities. In her opinion the science work for girls in the rural schools should be chosen from the fields of chemistry, botany, physiology, and biology, including bacteriology, to be taught in close correlation with cooking and sewing. Correlation and problem exercises or projects are recommended, and some correlations are suggested.

**Home economics applied to life, MARTHA VAN RENSSELAER** (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 821-824*).—The author discusses home economics as the medium of carrying into the home the principles of both science and art to establish high standards of living and right community and home ideals.

**Project teaching, J. A. RANDALL** (*Addresses and Proc. Nat. Ed. Assoc., 53 (1915), pp. 1009-1012*).—The chief object of this paper is to propose a technical definition for the word "project," and to expand the idea for which the term seems to stand. Illustrations of individual and community projects are given and their relative advantages discussed.

**Judging the dairy cow as a subject of instruction in secondary schools, H. P. BARROWS and H. P. DAVIS** (*U. S. Dept. Agr. Bul. 434 (1916), pp. 20, figs. 15*).—This bulletin gives specific directions, including classroom discussion and field practice, for the scoring and judging of the dairy cow as a practicum in the teaching of agriculture in secondary schools.

**Proceedings of the twentieth annual meeting of the American Association of Farmers' Institute Workers, edited by L. R. TAFT** (*Proc. Amer. Assoc. Farmers' Inst. Workers, 20 (1915), pp. 155, figs. 3*).—A detailed report of the proceedings of the meeting held at the University of California, Berkeley, August 12 to 14, 1915. It includes a report of the Farmers' Institute Work in the United States in 1914-15, by J. M. Stedman, and the following papers: Address of Welcome, by T. F. Hunt; Response, by T. B. Parker; President's

Annual Address, by T. B. Parker; The Farmer and Peace, by D. S. Jordan; How Can Smith-Lever Funds be Used for the Furtherance of Farmers' Institutes? by W. T. Clarke; The Ideal Institute Lecturer, E. C. Johnson; Movable Schools of Agriculture and Their Work, by G. I. Christie; The Cooperation of Farmers' Institutes With Other Educational Agencies, by F. S. Cooley; Demonstration Work in Farmers' Institutes, by J. M. Stedman; The Farmers' Responsibilities, by H. J. Waters; How Can We Help the Boys? by B. Knapp; Women's Institutes of the Province of Ontario, by G. A. Putnam; Extension Service for Women, by E. G. Peterson; Extension Work for Rural Women, by Mamie Bunch; Extension Work for Rural Communities, by Mary E. Sweeney; Home Demonstration and Its Possibilities, by Gertrude McChene; Equipment for Extension Work in Home Economics, by Ava B. Milan; Rural Work in Home Economics in Missouri, by May C. Macdonald; How Far Should Entertainment be Made a Feature of Farmers' Institute Work? by A. J. Cook; The Market Problem and How Can Farmers' Institutes Help to Solve It, by C. J. Brand; Tillage, Its Rationale and Its Dangers, by C. B. Lipman; Shall Extension Services Include the Social, Recreational, and Educational Improvement of Rural and Urban Districts? by W. D. Hurd; Organization and Methods in Home Economics, by Mrs. H. W. Calvin; and Home Demonstrations, by Mary E. Creswell. Statistics of farmers' institutes in the United States and in Canada for 1914-15 are included.

### MISCELLANEOUS.

**Annual Report of California Station, 1916** (*California Sta. Rpt. 1916, pp. 133, pl. 1, figs. 5*).—This contains the organization list and a report of the director on the work and publications during the year, including a list of the station projects and some data pertaining to the instruction and extension work of the college of agriculture. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Report of Kansas Station, 1915** (*Kansas Sta. Rpt. 1915, pp. 69, figs. 21*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1915, a report of the director summarizing the work and publications of the station, and two special articles. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Twenty-eighth Annual Report of Massachusetts Station, 1915** (*Massachusetts Sta. Rpt. 1915, pls. 1-2, pp. VIII+72a+194, pls. 8, figs. 11*).—This contains the organization list, reports of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1915, and reprints of Bulletins 163-167, previously noted. The experimental work recorded is for the most part abstracted elsewhere in this issue.

**Thirty-fifth Annual Report of Ohio Station, 1916** (*Ohio Sta. Bul. 300 (1916), pp. XXIV, figs. 2*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1916, and a report of the director summarizing the work and publications of the station during the year.

**Monthly bulletin of the Western Washington Substation** (*Washington Sta., West. Wash. Sta., Mo. Bul., 4 (1916), No. 7, pp. 16, fig. 1*).—This number contains brief articles on the following subjects: Home Canning, by T. J. Newbill; The Value of Cow-testing Associations, by O. E. Gibson; Dairy Farming Problems, by H. L. Blanchard; Hints on Storing and Marketing Potatoes, by J. L. Stahl; Fall Plowing, by E. B. Stookey; Getting Fall and Winter Eggs, by Mr. and Mrs. G. R. Shoup; and Concerning Mold on Berries, by A. Frank.

## NOTES.

---

**Alabama College and Station.**—G. C. Starcher, associate professor of horticulture and associate horticulturist at the Virginia College and Station, has been appointed professor of horticulture and horticulturist, vice Ernest Walker, resigned to engage in commercial work.

**Georgia Station.**—F. H. Smith, assistant chemist, has been appointed head of the department of chemistry beginning January 10. His work will be confined largely to animal nutrition along the lines already under way.

**Kansas College and Station.**—Among the changes effective January 1 was the resignation of Dr. James W. Benner, instructor in veterinary medicine, to become assistant professor in the veterinary department in the Michigan College. Dr. Benner has been succeeded by Dr. J. P. Scott, who was appointed a fellow in pathology in the college last fall. Kurt Peiser, assistant in dairy bacteriology, has resigned to become milk inspector for the Board of Health at Cleveland, Ohio, and has been succeeded by J. R. McClung, assistant in chemistry in the college. Dr. Thomas P. Haslam, pathologist in the station, has resigned to engage in commercial work.

**Michigan College.**—Dr. J. P. Hutton has resigned as assistant professor of veterinary surgery to engage in commercial work.

**Minnesota University.**—About 1,500 farmers and farmers' wives attended the annual week's short courses in the college of agriculture.

**Nevada University.**—Mrs. Edna C. Baker of Sparks, B. F. Curler of Elko, and F. Abel of Reno were elected to the board of regents, vice Messrs. Dodd, Henderson, and Pratt, effective January 1. The resignation of President A. W. Hendrick took place January 4, on demand of the board, and Robert Lewers was appointed acting president. Paul Gaston, comptroller, also resigned and was succeeded by C. H. Gorman, a former comptroller.

**New Jersey Stations.**—At a recent meeting of the board of managers of the State Station, James Neilson was elected president of the board, George E. DeCamp, vice-president, and Irving E. Quackenboss, secretary-treasurer. J. P. Helyar was appointed State seed analyst, also continuing at the head of the station seed laboratory.

Louis J. Kleinfeld, assistant chemist in the State Station, resigned December 1, 1916.

The three-year international egg-laying and breeding contest, begun November 1, 1916, at Vineland, is now in full operation. The entries number 100 pens of 10 birds each, representing all of the more important breeds.

**Ohio Station.**—C. B. Williams, agronomist, has been appointed associate director. G. K. Livasian has been appointed assistant in the soil survey, vice A. H. Huisken resigned.

**Oregon College.**—At the invitation of President Kerr the entire legislative assembly visited the college January 20, this being its first official visit in six years.

Carl L. Kennedy, assistant professor of animal husbandry, has resigned to become county agent of Polk County, Iowa.

**Pennsylvania College and Station.**—L. F. Reese, instructor in horticulture, resigned January 1. L. D. Jesseman has been appointed instructor in horticulture, effective January 15, and Albert White, assistant in vegetable culture at the Maryland College, has been appointed superintendent of greenhouses and instructor in horticulture, effective on the same date.

**South Carolina College and Station.**—J. N. Harper has resigned as dean of the agricultural department, director of the station, and agronomist to engage in commercial work.

**Tennessee University.**—J. C. Pridmore, associate professor of agronomy, resigned February 1 to engage in commercial work, and has been succeeded by R. B. Lowry.

**Utah College.**—W. W. Henderson has been appointed professor of zoology and entomology, vice E. G. Titus whose resignation has been previously noted.

**Virginia Station.**—K. E. Quantz, special assistant in horticulture, and R. H. Cook, superintendent of the Charlotte County substation, resigned December 31, 1916, to accept positions with the Government of Brazil. Mr. Cook has been succeeded by A. P. Moore, a 1916 graduate of the college. Dr. M. T. Smulyan, assistant entomologist for the State Crop Pest Commission, whose experimental work is affiliated with the station, also resigned December 31 to accept a position with the Bureau of Entomology of the U. S. Department of Agriculture.

**American Society of Agronomy.**—The ninth annual meeting of the American Society of Agronomy was held in Washington, D. C., November 13 and 14, with the largest attendance on record.

The presidential address was given by C. R. Ball at a joint session held with the Society for the Promotion of Agricultural Science and the American Farm Management Association. Mr. Ball took for his subject Some Problems in Agronomy, and suggested a long list of problems along agronomic lines that are yet unsolved. Among other things, he discussed the preparation of investigators, and emphasized the necessity of a broad fundamental training in the sciences and languages before the student began to specialize. Cooperation among institutions in experimental work was suggested, as well as the conducting of group studies. In conclusion he spoke of the evolution of procedure, the increasing refinements of methods, and the necessity of definitely outlining proposed work and keeping adequate records.

Other papers presented before the society included the following: The Carbon Dioxid Content of a Planted and Unplanted Limed and Unlimed Soil, by T. L. Lyon and J. A. Bizzell; The Possible Rôle of the Active Organic Matter of the Soil, by C. J. T. Doryland; Field Crops and Bacterial Transformation of Soil Nitrogen, by K. F. Kellerman and R. C. Wright; A Method of Determining the Volume Weight of Soils in the Field, by C. F. Shaw; Studies on the Relation of the Cob to Other Ear Characters in Corn, by A. E. Grantham; Composts as an Aid in Soil Building, by J. G. Lipman; The Relation of Live Stock to the Maintenance of Organic Matter in the Soil, by E. O. Fippin; What is Agronomy, by A. N. Hume; The Sugar Beet as a Factor in National Preparedness, by C. O. Townsend; The Soil Mulch, by L. E. Call and M. C. Sewell; The Effect of Inoculation on Yield and Protein Content of Alfalfa and Sweet Clover, by A. C. Arny and R. W. Thatcher; Heating Seed Rooms to Destroy Insects, by E. G. Montgomery; The Effect of Sodium Nitrate Applied at Different Stages of Growth on the Yield, Composition, and Quality of Wheat, by J. Davidson and J. A. LeClerc; and A New Device for Harvesting Grass and Grain Plots, by A. G. McCall.

The committee on soil classification and mapping made several suggestions for future work. The committee on the standardization of field experiments

suggested the compiling of a bibliography on the subject of field experiments. The committee on agronomic terminology reported that it is submitting a glossary of terms through the *Journal of the American Society of Agronomy* for the approval of the society.

The committee on varietal nomenclature suggested the creation of a register of varieties, along the lines followed in the herd-books, giving the history, ancestors, etc., of the variety. E. G. Montgomery, chairman of the committee, discussed some work that had been done along these lines in the classification of oats at the Cornell Station, and exhibited some mounted specimens.

The following officers were elected for the ensuing year: President, W. M. Jardine; Vice-Presidents, J. G. Lipman and J. A. Foord; Secretary, C. W. Warburton; and Treasurer, George Roberts.

**American Association for the Advancement of Agricultural Teaching.**—The seventh annual meeting of this association was held in Washington, D. C., November 14, 1916. Two main topics were presented for discussion, the content of the course in the college of agriculture for prospective high school teachers of agriculture and the high school course in agriculture.

Under the first of these, Dean C. F. Curtiss discussed the relation of the sciences. He thought that the science taught ought to be applied science, which will directly connect up with the work of the farmer and the community in which the teachers will serve.

As to general professional subjects, K. L. Hatch held that psychology is the basis of the professional preparation, but that whether or not there should be a course in general education is doubtful. The student's time is so taken up with technical work in agriculture that an effort should be made to reduce the professional preparation to the minimum. The course in agricultural education ought to include the principles of general methods. A certain amount of practice work should be required with real students, with real classes and conditions, and with problems teachers are going to meet. Professor Hatch also discussed at length the growing demand for a course in the college known as general science or elementary science. In discussing this paper R. W. Stimson laid stress upon the importance of training college teachers of agriculture, if for no other reason than that the prospective teachers coming under their influence may imitate good teaching.

G. A. Works took up *The Content of the Methods Course for High School Teachers of Agriculture*, outlining the work given in the New York State College of Agriculture. This course, which is given three or four times a year, is open only to seniors. It runs for a term with two discussion periods and one laboratory period  $2\frac{1}{2}$  hours in length each week. The class is limited to 50 and each laboratory section to 12 students. The laboratory and lecture work are closely correlated throughout the course, and special attention is given to the selection of material adapted to the high school pupil and to its arrangement in seasonal sequence. Other topics taken up are the place of the home project and the organization of study material for the recitation lesson, the laboratory, and the field trip. A visit to a near-by high school is made for the purpose of studying equipment, library, and home projects, and some work is done in chart making and bulletin collecting and cataloguing.

*The Relations of High School Agriculture to Agriculture as Taught in the Lang-grant College*, was the title of a paper read by D. J. Crosby, in which the subject was discussed along the lines of the report of the committee on instruction in agriculture of the Association of American Agricultural Colleges and Experiment Stations (E. S. R., 35, p. 705).

In a paper on *How to Connect the High School Work with Practical Farm Operations*, A. K. Getman suggested (1) a seasonal distribution of the topics

studied, the study to coincide with the operations on the farm, (2) provision for field and laboratory work, and (3) the use of the home project properly planned, accounted, summarized, and supervised.

C. H. Lane, in a paper on *The Content of High School Courses in Agriculture*, said that it is not merely a question of what is worth teaching and studying, but what is best considering all local conditions, equipment, time, teacher, community interests, adaptations, etc. Thus, the determination of the content and arrangement of a course in agriculture becomes a local problem and no general solution can be given that will apply equally well to all localities. The following outline of work was, however, suggested: First year, practical work on how plants grow, soils and fertilizers, and field crops or fruits and vegetables, the choice depending upon local conditions as regards available material and interest in home project work. The second year should be given to the study of live stock. After such general courses the student is prepared for more special work. In sections where horticulture is important the third year may well be spent in such specialized branches of plant production as fruit growing, practical work on soils and fertilizers, cover crops, etc., as relate to the production of fruit, or market or vegetable gardening, and one-third of a unit on improvement of home grounds and ornamental planting.

Similar specialized courses should be provided in districts where one or more field crops, dairying, or some other special phase of animal husbandry predominates. In districts having broad interests in agriculture the school should be equipped to offer a number of special courses during the third and fourth years. While the subject of tools, implements, and machinery is necessarily considered in connection with crop production, the subject of farm mechanics is deemed sufficiently important to receive special attention during the fourth year. A half unit in rural economics and farm management should not preclude careful accounting in connection with the projects of each of the previous years nor the study of simple methods of accounting in connection therewith.

The officers elected for the ensuing year are W. H. French, Michigan Agricultural College, president; A. C. Monahan, U. S. Bureau of Education, vice-president; and C. H. Lane, U. S. Department of Agriculture, secretary-treasurer.

**Agricultural Education at the Fourteenth International Live Stock Exposition.**—After a lapse of three years, occasioned by the foot-and-mouth disease situation, the Fourteenth International Live Stock Exposition was held at Chicago in December, 1916. The agricultural colleges were again strongly in evidence, both the grand champion and the reserve champion in the bullock section coming from the University of California.

A new feature of the show is to be a special exhibit each year from some one agricultural college. The institution selected to initiate this practice was the University of Illinois, which depicted in miniature its campus and buildings and likewise a model farm divided into fields supporting a profitable and soil building rotation as well as much other illustrative material. A number of domestic science demonstrations were also given by the Iowa College, while the U. S. Department of Agriculture showed moving pictures of agricultural interest.

At the students' stock-judging contest, 16 institutions were represented, three for the first time. The first place was awarded to the team from Purdue University, second to the Iowa State College, and third to the Ohio State University.

**Colonization of Ex-soldiers and Sailors in England.**—An estate of 2,363 acres, near Patrington in Yorkshire, has been acquired for a land settlement colony of ex-service men. When fully developed the colony will comprise a central

farm of about 200 acres and 60 small holdings of about 35 acres each. On each of these holdings, a cottage and the necessary farm buildings will be built, while the central farm will be equipped with machinery, horses, etc., which may be hired by the settlers.

Applicants will receive training when necessary on the central farm until fitted to take up a holding independently. Cooperative methods are to be followed in the purchase of supplies and the disposal of produce for the entire tract. The enterprise is said to be the first of its kind in Great Britain. R. N. Dowling, organizer of agricultural education to the Lindsey County Council of Lincolnshire, has been appointed director of the colony.

**Miscellaneous.**—Following the death of Hon. James S. Duff, Minister of Agriculture for Ontario, the Prime Minister, Hon. W. H. Hearst, has taken charge of that department in addition to his other duties. President G. C. Creelman of the Ontario Agricultural College has also been appointed commissioner of agriculture for the Province, a new position in which he will act as chief adviser to the Prime Minister on matters of agricultural policy.

The Kaiser-i-Hind Medal of the First Class, conferred for public services in India, was bestowed on New Year's Day upon Dr. H. H. Mann, principal of the Agricultural College of Poona and agricultural chemist to the Government of Bombay.

William Marriott, assistant secretary of the Royal Meteorological Society from 1872 to 1915, and editor of the *Meteorological Record* from 1881 to 1911, as well as a frequent contributor to other meteorological publications, died at Dulwich, England, December 28, 1916, at the age of 68 years.

Valparaiso University, located at Valparaiso, Ind., has received a gift of 400 acres of land, valued at over \$50,000, from William F. Pinney and Miss Myra Pinney for the use of its department of agriculture.

J. A. McLean, formerly of the Massachusetts College, has been appointed professor of animal husbandry in the University of British Columbia, and has entered upon his duties.

Plans are under consideration for the establishment by the Board of Agriculture and Fisheries and the Board of Development Commissioners of Great Britain of a research institute for problems relating to agricultural machinery at Cambridge University in connection with the existing schools of agriculture and engineering.

Officers for the current year were elected by the American Phytopathological Society at its New York City meeting, December 27-30, 1916, as follows: President, M. T. Cook of the Delaware station; vice president, Charles Brooks, U. S. Department of Agriculture; councilor, H. S. Jackson of the Indiana station.

F. A. Stockdale, director of agriculture in Mauritius, has been appointed director of agriculture in Ceylon and has been succeeded by Dr. H. A. Tempany, chemist and superintendent of agriculture in the Leeward Islands.

Trees in medicine, Foote.....	244
Marketing of woodlot products, Calland.....	244
Service tests of treated and untreated fence posts, Bradley.....	244
Forest products of Canada, 1915.—Lumber, lath, and shingles.....	244

## DISEASES OF PLANTS.

Pathological quarantines in 1915, Beattie.....	244
Interesting finds in the phytopathological inspection service for 1915, Lyman.....	245
Growth of parasitic fungi in concentrated solutions, Hawkins.....	245
Culture work on the heteroecious rusts of Colorado, Bethel.....	245
Rusts in the Department of Sotshi, Voronikhin.....	245
Two wild hosts of <i>Bacterium solanacearum</i> , Fulton and Stanford.....	245
Life histories of Melanops, Shear and Beckwith.....	246
Morphology and developmental conditions of <i>Sclerotinia trifoliorum</i> , Peglion.....	246
The perfect stage of <i>Septoria ribis</i> , Stone.....	246
Occurrence of <i>Puccinia glumarum</i> in the United States, Humphrey and Johnson.....	246
Biologic forms of <i>Puccinia graminis</i> , Stakman and Piemeisel.....	246
Barberry and cereal rust in Denmark, Lind.....	247
<i>Puccinia</i> on spring wheat, Litvinov.....	247
Further results in controlling barley diseases by seed treatment, Johnson.....	247
The deterioration of maize infected with <i>Diplodia zeæ</i> , van der Bijl.....	247
Notes on an heretofore unreported leaf disease of rice, Godfrey.....	247
Leaf smut of timothy, Osner.....	247
A newly noted Phyllosticta on alfalfa in America, Jones.....	248
Some root diseases of the bean, Burkholder.....	248
Cabbage yellows and the relation of temperature to its occurrence, Gilman.....	248
Fourth progress report on Fusarium-resistant cabbage, Jones.....	248
Relation between storm and disease in Texas, Blodgett.....	248
Cucumber diseases in the Middle West, Gilbert.....	248
Angular leaf spot, a bacterial disease of cucumbers, Carsner.....	249
Steaming of soil for the control of root rot of ginseng, Brann.....	249
The development of <i>Mycosphaerella pinodes</i> in pure culture, Vaughan.....	249
<i>Spongospora subterranea</i> and <i>Phoma tuberosa</i> on the Irish potato, Melhus et al.....	249
The potato powdery scab quarantine, Beattie.....	250
The blackleg disease of potatoes caused by <i>Bacillus solanisaprus</i> , Murphy.....	250
Late blight and rot of potatoes caused by <i>Phytophthora infestans</i> , Murphy.....	250
Studies in the control of storage rots of the sweet potato, Taubenhaus.....	250

	Page.
Two interesting diseases on greenhouse tomatoes, Cook and Schwarze.....	250
Observations on fire blight in the Yakima Valley, Washington, Hotson.....	250
Black rot, leaf spot, and canker of pomaceous fruits, Hesler.....	250
Treatment for anthracnose.....	251
A wilt disease of the columbine, Taubenhaus.....	251
Sclerosis of <i>Forsythia viridissima</i> , Peglion.....	251
A new disease of bamboo, Turconi.....	251

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

A bibliography of British ornithology, Mullens and Swann.....	251
Notes on India earthworms, Heimburger.....	251
A review of applied entomology in the British Empire, Hewitt.....	251
How gases enter insects, Moore.....	251
A method of keeping alcoholic specimens, Bishopp.....	252
A new insecticide, Smith.....	252
Notes on some miscellaneous economic insects found in New Jersey, Weiss....	252
Report of the entomologist, Wolcott.....	252
Insect pests of the year, Bovell.....	252
Report of the economic biologist, Bodkin.....	252
[Reports of] division of entomology, Jepson.....	252
Insect and arachnid pests of 1915, Macdougall.....	252
Sarcosporidia, van de Wall de Kock.....	252
Grasshopper control in relation to cereal and forage crops, Walton.....	252
Some northern Georgia Acridiidae, Allard.....	252
Orthoptera and orthopteran habitats in vicinity of La Fayette, Indiana, Fox..	252
Parthenogenesis in <i>Anthothrips verbasci</i> , Shull.....	252
Descriptions of the new Thysanoptera, Hood.....	253
Feeding habits of <i>Sinea diadema</i> , Parker.....	253
The potato tingid ( <i>Recareduus</i> sp.), Dutt.....	253
Monograph of the North American species of <i>Orthotylus</i> , Van Duzee.....	253
The Anoplura and Mallophaga of North American mammals, Kellogg and Ferris..	253
A catalogue and host list of the Anoplura, Ferris.....	253
Eighty-seven generations in parthenogenetic pure line of <i>Aphis avenæ</i> , Ewing..	253
A review of the Pterocommini, Baker.....	253
Aphididæ on the apple in Britain and a new species from Africa, Theobald....	253
Satisfactory method of rearing mealy bugs for use in parasite work, Branigan..	253
A new fungus on the green scale, Nowell.....	253
The common cabbage worm ( <i>Pontia rapæ</i> ), Chittenden.....	254
The fall army worm, or "grass worm," and its control, Walton and Luginbill..	254
Campaign against surface caterpillar at Mokameh in 1913, Woodhouse and Dutt..	254
Campaign against surface caterpillar at Mokameh in 1914-15, Dutt.....	254
The taxonomic value of some larval characters in the Lepidoptera, Heinrich..	254
The apple leaf-sewer, Leach.....	254
Descriptions of new North American Microlepidoptera, Busck.....	254
Transmission experiments with <i>Anopheles punctipennis</i> , Mitzmain.....	255
Sea water and <i>Aedes sollicitans</i> and <i>A. cantator</i> , Chidester and Patterson.....	255
A mosquito collecting device, Griffiths.....	255
Mycetobia and the classification of the Diptera, Knab.....	255
Notes on some genera of Syrphidæ, with descriptions of new species, Shannon..	255
Synopses of Zodion and Mycopa, with notes on other Conopidæ, Banks.....	255
Description of two new tachinids, Townsend.....	255
A tachinid parasite reared from an adult capsid, Leonard.....	255
Rearing of <i>Winthemia quadripustulata</i> from rhyncophorous larva, Parker.....	255
New Tachinidæ from North America, Smith.....	255
More light on <i>Myiophasia</i> , Aldrich.....	256
Note on <i>Myiophasia aenea</i> , Townsend.....	256
Observations on the habits and parasites of common flies, Graham-Smith.....	256
The changes of the blowfly larva's photosensitivity with age, Patten.....	256
The spike-horned leaf-miner, Luginbill and Urbahn.....	256
Contribution to the American Siphonaptera, Jordan and Rothschild.....	257
A <i>Nosema</i> parasitic in the dog flea.....	257
A catalogue of Philippine Coleoptera, Schultze.....	257
A review of North American tortoise beetles, Barber.....	257
A new enemy of the black locust, Culbertson.....	257
Biology of <i>Cerambyx heros</i> , Barbey.....	257

	Page.
The cane-borer beetle in Hawaii and its control, Muir and Swezey.....	257
Orchard bark beetles and pinhole borers, and how to control them, Brooks....	258
Determination of abdominal and thoracic areas of cerambycid larvæ, Craighead.	258
Scientific queen rearing, Quinn.....	258
The Isle of Wight bee disease, Imms.....	258
A new bee of the genus <i>Dianthidium</i> , Rohwer.....	258
Notes on the biology of <i>Paraphelinus speciosissimus</i> , McConnell.....	258
A few observations on the apple maggot parasite, <i>Blastodes rhaqoletis</i> , Good....	259
One new genus and five new species of ichneumon flies, Viereck.....	259
New miscellaneous chalcidoid Hymenoptera, Girault.....	259
Life history of <i>Habrocytus medicaginis</i> , Urbahns.....	259
Description of eleven new species of chalcid flies, Girault.....	260
Descriptions of and observations on some chalcidoid Hymenoptera, Girault...	260
A new genus of pteromalid Hymenoptera from North America, Girault.....	260
A new genus of lalapine chalcidflies from the United States, Girault.....	260
The pear leaf-worm, Nougaret, Davidson, and Newcomer.....	260
Some American Hymenoptera, Crawford.....	261
The citrus mite named and described for the first time, McGregor.....	261
A new mite from the Hawaiian Islands, O'Gara.....	261
The dispersal of leaf-blister mite of cotton.....	261

## FOODS—HUMAN NUTRITION.

On the use of certain yeast nutriment in bread making, Kohman et al. ....	261
A cause of mustiness in bread, Wright.....	261
Manufacture of [soy] bean milk at Changsha [China], Johnson.....	262
Biochemistry of cod-liver oil, Funk.....	262
Studies on coal tar colors.—I. Fat-soluble dyes, Salant and Bengis.....	262
[Food and drug inspection], Ladd and Johnson.....	262
The food problem in wartime from the standpoint of a physician, Devoto.....	263
The increase in the cost of food since the outbreak of war, Wood.....	263
The food value of Great Britain's food supply, Thompson.....	263
The German food supply and its political economy, Schumacher.....	263
Studies on the growth of man, I-IV, Robertson.....	263
The use of boiled milk in infant feeding and elsewhere, Brennemann.....	264
The use of malt soup extract in infant feeding, Hoobler.....	264
The relation of diet to beri-beri, Vedder.....	264
The influence of flesh feeding on urinary creatinin, Burns and Orr.....	264
Feeding experiments with tyrosin reduced to a minimum, Totani.....	265
Feeding experiments with kynurenic acid, Asayama.....	265
Rôle of leucocytes in metabolism of carbohydrates, Levene and Meyer.....	265
The mechanism of cholesterol absorption, Mueller.....	265
A study of the electrolytic method of silver cleaning, Lang and Walton, jr....	266

## ANIMAL PRODUCTION.

The respiratory exchange of animals and man, Krogh.....	266
The growth and variability in the body weight of the albino rat, King.....	267
Influence of exercise on the growth of organs in the albino rat, Hatai.....	267
Composition and physiological activity of the pituitary body, I, II, Fenger....	267
Commercial feeding stuffs, Jones, jr., Fuller, Proulx, Cutler, and Roop.....	268
Concentrated commercial feeding stuffs, Turner and Spears.....	268
[Animal husbandry studies].....	269
Feeding for beef in Alberta, Hutton and Fairfield.....	270
Characteristics of sheep wool and determining its quality, von Allwörden....	270
The fleece of coarse-wool sheep, Kovalevskii.....	270
Sorrel color in horses, McCann.....	270

## DAIRY FARMING—DAIRYING.

Milk production cost accounts: Principles and methods, Larson.....	271
Labor on dairy farms as influenced by milking machines, Humphrey.....	272
Statistical weighting for age of advanced registry cows, Holdaway.....	272
Liver meal for milch cows: Influence on milk and dairy products, Isaachsen....	273
A study of factors affecting the composition of sheep's milk, Fabre.....	273
[Dairy industry in New Zealand], Cuddie.....	273
The milk supply of Paris before and during the war, Lucas.....	273

	Page.
The bacteriological examination of fresh milk, Ritchie.....	273
Bacterial testing versus dairy inspection, North.....	273
Some observations on causes of high bacterial counts in market milk, Pease.....	274
The experience of New York City in grading market milk, Brown.....	274
The pasteurization of milk from the practical viewpoint, Kilbourne.....	274
Milk clarifiers, Bahlman.....	274
Some observations on homogenized milk and cream, Baldwin.....	275
Condensed milk in Bermuda, Eells.....	275
Manufacture and marketing of creamery butter in the South, Potts and White..	275

## VETERINARY MEDICINE.

Report of the veterinary director general for 1915, Torrance.....	275
Report for 1914 of the principal of the Royal Veterinary College, McFadyean..	275
A new model of double pipette holder and the technique, Hecker.....	275
Lupines as poisonous plants, Marsh, Clawson, and Marsh.....	276
Studies on the action of glycerin, I, Simon.....	276
Action of amino acids, peptids, and proteins on hemolysis, Zunc and György...	276
Anaphylaxis produced by sensitization through the vagina, Hamm.....	277
The use of polyvalent sera, Cuvellier.....	277
A case of anthrax, Reinle and Archibald.....	277
Is <i>Bacillus abortus</i> pathogenic for human beings? Cooledge.....	277
The bull as a disseminator of contagious abortion, Hadley and Lothe.....	277
The causative organism of foot-and-mouth disease, Stauffacher.....	278
Investigation on the presence of the tubercle bacillus in milk, Charles.....	278
The clinical value of complement fixation in tuberculosis, Miller.....	278
Chemotherapy of tuberculosis.—First experimental report, Koga.....	278
The chemotherapy of tuberculosis.—First clinical report, Koga.....	279
The etiology of bovine metritis, Eggink.....	279
<i>Bacterium pyogenes</i> associated with multiple arthritis in a hog, Ward.....	280
Swine erysipelas and hog cholera, Ferreira.....	280
Agglutinins in hog-cholera immune serum for <i>Bacillus suispestifer</i> , Wehrbein...	280
The virulent salt solution used in production of hog-cholera serum, Robbins..	280
Lameness of the horse, Lacroix.....	280
Effect of feed inoculated with <i>Bacillus coli</i> , Graham and Himmelberger.....	280
Sclerostome parasites of the horse in England, I, Boulenger.....	280
Histopathology of chicks with <i>Bacterium pullorum</i> , Gage and Martin.....	281
The poisonous effects of the rose chafer upon chickens, Lamson, jr.....	281

## RURAL ENGINEERING.

The flow of water in wood-stave pipe, Scobey.....	281
New method of deriving weir formulas, Running.....	282
Design of small lined canals.....	282
Surface water supply in Washington and upper Columbia River basin, 1913...	282
Rogue River and Willamette Valley investigations, Whistler and Lewis.....	282
John Day Project: Irrigation and drainage, Whistler and Lewis.....	283
The type of colon bacillus occurring in surface waters, Rogers.....	284
Running water possible for every country home, Blasingame.....	284
First report of the state engineer of New Mexico, French.....	284
Annual report of state engineer and surveyor of New York, 1915, Williams.....	284
Third biennial report, State Road Commission 1913-14.....	284
[First annual report State Road Bureau West Virginia], Williams et al.....	284
New road laws of Oklahoma as passed by the legislature of 1915 and 1916.....	285
Road maintenance and its significance, James.....	285
The construction of roads and pavements, Agg.....	285
Should wider joints be provided in concrete roads laid late? Van Scoyoc....	285
General specifications for concrete bridges, Watson.....	285
Concrete and reinforced concrete, Webb and Gibson.....	285
Calcium chlorid hastens seasoning of concrete.....	286
Tensile strength of Portland cement mortars containing lime, Fuller.....	286
The economical brick mortar.....	286
Handbook of practical smithing and forging, Moore.....	287
Gas-engine principles, Whitman.....	287
Tractor engines, McVicker.....	287
A novel cooler for internal combustion engines.....	287

	Page.
Carburetion, Dean.....	288
Official tests of mechanical cultivation.....	288
Modern piggery buildings, Potts and Brooks.....	288
The construction of silos, Kuijsten.....	288

## RURAL ECONOMICS.

The country town, Anderson.....	288
The social survey: A bibliography, compiled by Potter.....	288
Proceedings of thirty-fifth session of Farmers' National Congress.....	288
Value to farm families of food, fuel, and use of house, Funk.....	289
Losses from selling cotton in the seed, Creswell.....	289
The elevator movement in the Pacific Northwest, Lewis.....	289
Report of the Bureau of Markets, 1915.....	289
The Federal Farm Loan Act, Palmer.....	289
The farm loan primer.....	289
National farm loan associations.....	289
How farmers may form a national farm loan association.....	289
The North Carolina credit union, Camp.....	289
Report on cooperative societies in Bihar and Orissa for the year 1914-15.....	290
The supply of agricultural implements by cooperative societies, Burt.....	290
Cattle insurance societies, Chatterjee.....	290
Employment on land in England and Wales of discharged sailors and soldiers..	290
Farming and food supplies in time of war, Rew.....	290
Our food supply, Turnor.....	290
[Report of the German food supplies committee].....	290
Vacant public lands on July 1, 1915, and July 1, 1916.....	290
The acquisition of title to public lands in Alaska, compiled by Tallman.....	290
Vermont farms.....	290
Report of Bureau of Agriculture, Labor, and Statistics of Kentucky.....	290
[Agriculture in Hawaii].....	291
Grain statistics of Canada, 1914-15, Magill, Staples, and Jones.....	291
[Agricultural statistics of São Paulo].....	291
Trade in agricultural products of Great Britain and Ireland, 1915, Van Rijn...	291
Fourth report of the board of agriculture for Scotland, Wright et al.....	291
[Agricultural production in Austria, 1915].....	291
The recent development of German agriculture, Middleton.....	291
Agricultural statistics of British India, 1913-14, Shirras.....	291

## AGRICULTURAL EDUCATION.

Agricultural and industrial education with recommendations.....	291
Agricultural education in New South Wales, Sedgwick.....	292
Agricultural education in the State of Victoria, Australia, Harrison.....	292
Gardening and farming in the Philippine schools, Foreman.....	292
The Philippine public-school system in cooperation with the home, Miller...	292
Rural science and school gardening, Johns.....	292
High-school extension in agriculture, Lane.....	293
School credit for boys' and girls' club work and extension activities, Benson..	293
How boys and girls respond to home work in a large city, Palmer.....	294
Girls' and boys' club work: A manual for rural teachers, Creswell.....	294

## MISCELLANEOUS.

Twenty-second Annual Report of Montana Station, 1915.....	294
Twenty-eighth Annual Report of Vermont Station, 1915.....	294
Publications for free distribution.....	294
List of available publications.....	294

## LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	<i>Page.</i>	<i>U. S. Department of Agriculture—Contd.</i>	<i>Page.</i>
Alabama College Station:	496	Bul. 423, Labor Requirements of Dairy Farms as Influenced by Milking Machines, H. N. Humphrey.....	272
Bul. 191, June, 1916.....	212	Bul. 432, The Spike-horned Leaf-miner, an Enemy of Grains and Grasses, P. Luginbill and T. D. Urbahns.....	256
California Station:		Bul. 435, The Apple Leaf-sewer, B. R. Leach.....	254
Bul. 270, Aug., 1916.....	234	Bul. 438, The Pear Leaf-worm, R. L. Nougaret, W. M. Davidson, and E. J. Newcomer.....	260
Hawaiian Sugar Planters' Station:		Bul. 444, False Blossom of the Cultivated Cranberry, C. L. Shear....	240
Bul. 13, Ent. Ser., Sept., 1916.	257	Bul. 447, Water Penetration in the Gumbo Soils of the Belle Fourche Reclamation Project, O. R. Mathews.....	210
Indiana Station:		Bul. 449, A Study of the Electrolytic Method of Silver Cleaning, H. L. Lang and C. F. Walton, jr.	266
Bul. 190, Aug., 1916.....	268	Farmers' Bul. 747, Grasshopper Control in Relation to Cereal and Forage Crops, W. R. Walton....	252
Kentucky Station:		Farmers' Bul. 752, The Fall Army Worm, or "Grass Worm," and Its Control, W. R. Walton and P. Luginbill.....	254
Bul. 203, July, 1916.....	268	Farmers' Bul. 763, Orchard Bark-beetles and Pinhole Borers, and How to Control Them, F. E. Brooks.....	258
Michigan Station:		Farmers' Bul. 766, The Common Cabbage Worm, F. H. Chittenden.....	254
Tech. Bul. 27, Mar., 1916.....	210	Farmers' Bul. 768, Dwarf Broom Corns, B. E. Rothgeb.....	229
Montana Station:		Farmers' Bul. 769, Growing Grain on Southern Idaho Dry Farms, L. C. Aicher.....	227
Bul. 110, Feb., 1916.....	227	Farmers' Bul. 775, Losses from Selling Cotton in the Seed, C. F. Creswell.....	289
Twenty-second An. Rpt., 1915.....	208, 231, 236, 294	Office of the Secretary:	
New York Cornell Station:		Circ. 66, Suggestions for the Manufacture and Marketing of Creamery Butter in the South, R. C. Potts and W. White.....	275
Bul. 379, Aug., 1916.....	250		
North Dakota Station:			
Bul. 118, Sept., 1916.....	206		
Spec. Bul., vol. 4, No. 7, Sept., 1916.....	262		
Ohio Station:			
Bul. 302, Aug., 1916.....	244		
Oregon Station:			
Bul. 139, Aug., 1916.....	237		
Utah Station:			
Bul. 146, Sept., 1916.....	234		
Vermont Station:			
Bul. 193, Feb., 1916.....	242		
Circ. 9, Apr., 1915.....	294		
Twenty-eighth An. Rpt., 1915.	294		
West Virginia Station:			
Circ. 23, Oct., 1916.....	294		
<i>U. S. Department of Agriculture.</i>			
Jour. Agr. Research, vol. 7:			
No. 4, Oct. 23, 1916.....	225, 259		
No. 5, Oct. 30, 1916.....	245, 249		
Bul. 354, Forests of Porto Rico, L. S. Murphy.....	243		
Bul. 376, The Flow of Water in Wood-stave Pipe, F. C. Scobey.	281		
Bul. 405, Lupines as Poisonous Plants, C. D. Marsh, A. B. Clawson, and H. Marsh.....	276

## RECENT WORK IN AGRICULTURAL SCIENCE.

---

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Chemical composition of alfalfa as affected by stage of maturity, mechanical losses, and condition of drying, C. O. SWANSON and W. L. LATSHAW (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 726-729).—From a study of the chemical composition of alfalfa as affected by variations in maturing and curing, the authors have found at the Kansas Experiment Station that alfalfa cut in the bud stage has the largest ash and crude protein and the smallest crude fiber and nitrogen-free extract content. "In each successive stage the crude fiber and nitrogen-free extract increases, and the crude protein and ash decrease. In pounds per ton the alfalfa cut in the earlier stages has more of crude protein and less of crude fiber. The total amount of any or all nutrients produced per acre depends to a large extent on the yield.

"The leaves and stems differ in content of ash, ether extract, and nitrogen-free extract, but the greatest difference is in the percentage of crude protein and crude fiber. The leaves contain over two and a half times as much protein as the stems, while the stems contain over two and a half times as much crude fiber as the leaves.

"In harvesting and handling there is a large loss of leaves, which loss affects the composition of the hay in an increase of crude fiber and a decrease of crude protein. The alfalfa cured in the sun has a larger pure protein content, as determined by Stutzer's method, than that cured in the shade. This difference is so great as to more than offset the influence of the loss of leaves. The differences in respect to pure protein content were most pronounced in the alfalfa cut in the earlier stages."

The chemical composition of *Oscillaria prolifica*, B. B. TURNER (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1402-1417, figs. 5).—The air-dried material examined was found to have the following percentage composition: Moisture, 9.7 per cent; protein, 46.25; ether extract, 2.2; fiber and nitrogen-free extract, 35.5; and ash, 6.4 per cent (a small part due to fine sand unavoidably collected with the alga).

By extraction with various solvents no crystalline and easily identified characteristic substances were found in any considerable quantity in the alga. A small quantity of a crystalline magnesium salt of an organic acid (possibly caproic) was obtained. Saponin was not obtained in any appreciable quantity. A glucosid or a polysaccharid having physical properties similar to saponin was, however, detected.

"The bad smell and taste of the decaying alga appears to be due largely to higher acids of the fatty (butyric) series, some of which were separated; indol

or skatol from decomposition of the proteins seems also to be present in traces. The fresh alga contains an aromatic compound soluble in petroleum spirit which causes a characteristic odor. The spectra have been determined of various coloring matters from the alga, a 'chlorophyll' similar to that of the higher plants, and a blue substance soluble in water and in glycerol, with an intense red fluorescence, having properties which indicate that it is either associated with and carried down by the proteins in solution or itself has similar precipitation properties. This substance, which is believed to be new and may be allied chemically to the chlorophyll of the alga, has been named 'algocyan.'

The principal carbohydrate found was a pectin-like substance, insoluble in water, which on heating formed a jelly. It was slowly hydrolyzed by 5 per cent sulphuric acid. On examination of the hydrolytic products the presence of a nonreducing substance with a high positive rotation and a reducing sugar with a smaller rotation was indicated. A small quantity of a phenyl hydrazin compound, melting point 217° C., containing about 11 per cent of nitrogen was also obtained, but could not be identified with any known compound.

A modification of the Kjeldahl method for the determination of nitrogen, in which as little as from 5 to 10 mg. of sample and containing 1 mg. or less of nitrogen can be used, has been devised and is described in detail. A new form of extraction apparatus suitable for a continuous extraction with large quantities of material is also described.

**Barium in tobacco and other plants, BONNIBEL ARTIS and H. L. MAXWELL** (*Chem. News*, 114 (1916), No. 2959, pp. 62, 63).—Using the method for the determination of barium in plant materials essentially as described by McHargue (*E. S. R.*, 30, p. 502), the authors report the following percentages of barium (as BaSO<sub>4</sub>) in the materials examined: Havana tobacco from Cuba, leaf 0.0608, stem 0.076; broadleaf tobacco grown in Pennsylvania, leaf 0.0648, stem 0.078; Havana tobacco grown in Connecticut, leaf 0.06, stem 0.072; Pennsylvania tobacco, leaf 0.098, stem 0.128; Sumatra tobacco, leaf 0.0308, stem 0.0408; Wisconsin tobacco, leaf 0.0192, stem 0.028; tobacco grown in New York, leaf 0.0132, stem 0.504; dogwood leaf 0.0224; cottonwood leaf 0.0052; cherry leaf 0.0392; black-locust leaf 0.0324; mulberry leaf 0.0696; elm leaf 0.0356; linden leaf 0.0152; wild-olive leaf 0.0048; plum leaf 0.0372; box-elder leaf 0.036; hard-maple leaf 0.0368; walnut leaf 0.0752; and pear leaf 0.0196. The following results were obtained in the examination of immature leaves gathered in May soon after their appearance: Soft maple 0.0273; wild grape 0.0941; wild cherry 0.0336; box elder 0.0295; cottonwood 0.0528; lime 0.0435; cherry 0.0134; elderberry 0.0143; black walnut 0.0096; sumac 0.0071; elm 0.0182; and blackberry 0.0086.

The percentage of ash in the tobaccos analyzed is also reported.

**The synthesis of a new tripeptid, glycocyamilglycylglycin (guanidoglycylglycylglycin), A. CLEMENTI** (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 12, pp. 806-811).—The author describes the preparation of the new tripeptid from diglycylglycin and cyanamid.

**The isomeric pentacetates of glucosamin and of chondrosamin, C. S. HUDSON and J. K. DALE** (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1431-1436).

**The optical rotatory powers of some acetylated derivatives of maltose, cellose, and lactose, C. S. HUDSON and R. SAYRE** (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 9, pp. 1867-1873).

**An automatic pipette, A. LOWY** (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 734, 735, figs. 3).—An automatic stopcock pipette is described in detail. Advantages claimed for it are that an exact measured volume of liquid drawn into the pipette can be controlled automatically by the operator; that the necessity of adjusting, maintaining, and manipulating the exact volume of the liquid

after it has passed above the graduation mark is obviated; and that it is exceedingly easy to manipulate.

**The determination of aluminum as oxid,** W. BLUM (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1282-1297, figs. 2).—From experiments reported it was found with a hydrogen electrode and suitable indicators that the precipitation of aluminum hydroxid by ammonium hydroxid is complete when  $[H^+]$  ranges from  $10^{-6.5}$  to  $10^{-7.5}$ . These points are approximately defined by the color change of methyl red and rosolic acid. The presence of ammonium chlorid is advantageous in controlling the alkalinity and in coagulating the precipitate. Solutions of ammonium nitrate and chlorid are equally satisfactory for washing the precipitated hydroxid. For the determination of aluminum the following procedure is recommended:

To the solution containing at least 5 gm. of ammonium chlorid per 200 cc. (or an equivalent amount of hydrochloric acid) a few drops of methyl red are added and the solution then heated just to boiling. Ammonium hydroxid is carefully added until the color of the solution changes to a distinct yellow. Boiling is continued for one or two minutes and the precipitate filtered at once and washed thoroughly with hot 2 per cent ammonium chlorid or nitrate solution. The hydroxid is ignited in a platinum crucible and after all the carbon is burnt off is blasted for five minutes. The crucible is then covered and placed in a desiccator until cool. After weighing, a second blasting of five minutes is desirable, as it permits of a more rapid weighing and, consequently, more accurate results.

It is indicated that the crucibles containing the ignited alumina should be kept covered in the desiccator and on the balance. Five or 10 minutes blasting is sufficient for precipitates containing from 0.1 to 0.2 gm. aluminum oxid. The presence of ammonium chlorid during ignition causes no appreciable loss of alumina.

**Notes on the determination of aluminum,** C. F. SIDENER and E. PETTIJOHN (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 714-716).—Experimental data submitted show that boiling the solution for one minute completely precipitates all aluminum present, and that longer boiling may lead to a re-resolution of part of the precipitate. The complete removal of ammonium chlorid from the precipitate before ignition was found not to be necessary. A great excess of ammonium hydroxid should be avoided during precipitation and should never be more than 1 or 2 cc. per 250 cc. of solution. When the precipitate is large it must be blasted for 40 minutes to insure its being reduced to a constant weight, as the ignited alumina is strongly hygroscopic. See also a previous note by Daudt (*E. S. R.*, 34, p. 205) and that by Blum, noted above.

**A study of the silver arsenate test for arsenic,** L. J. CURTMAN and P. DASCHAVSKY (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1280-1282).—The authors have found that with pure solutions of arsenate the test with silver nitrate is sensitive to 0.02 mg. of arsenic. Ammonium nitrate was found to have no influence on the detection of 0.2 mg. of arsenic as sodium arsenate. A procedure in which the test is capable of detecting 0.5 mg. of arsenate with certainty is outlined.

**Titrametric determination of nitrites,** B. S. DAVISSON (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 9, pp. 1683-1687, fig. 1).—The author, at the Ohio Experiment Station, reviews the earlier methods for the titrametric determination of nitrites and outlines a procedure based on the nitrous acid-potassium iodid reaction. A special form of aeration flask used in the method is described.

Analytical data submitted indicate the accuracy of the modified procedure. Organic matter in soil extracts does not materially affect the results. When

necessary, however, the nitrites may be removed from a second portion of the sample by boiling with acetic acid and the effect of the organic matter determined by a blank titration.

It is concluded that "nitrous nitrogen can be determined titrametrically when care is taken to expel the air from the titration flask with some gas which will not affect the determination."

Notes on soil analysis, K. GEDROITS (*Zhur. Opytn. Agron.*, 16 (1915), No. 1, pp. 83-94).—The determination of the loss in soils which do not contain carbon dioxide, alkalis, and chlorids of metals by calcination at temperatures from 530 to 560° C. showed that within these limits the higher the temperature the smaller was the loss. The same phenomenon was observed for soils in general.

Determination of the loss by calcination for soils containing calcium carbonate and chlorids of metals showed during a period of one hour at the temperature noted above the same results as calcination of soils not containing these substances. If the soils contained magnesium carbonate in addition to the above, the procedure could not be used on account of the decomposition of magnesium carbonate. The determination is rendered still more difficult if in addition to magnesium carbonate the soil contains considerable quantities of chlorids, as the effect of high temperature on the latter will depend on their composition and on the composition of the soil, containing possibly sodium, magnesium, calcium, and other chlorids. Calcium and magnesium chlorids are not volatilized on heating but may be decomposed to a greater or lesser extent, especially magnesium chlorid, on account of the hydrolytic action of the water in the soil. Sodium chlorid is volatilized entirely by heating over the flame of a Teclu burner.

It is indicated that the processes taking place in the soil during calcination are not clearly understood. The temperature of heating should apparently be from about 530 to 560°.

Decomposition of a soil containing sulphates by means of hydrofluoric acid is a very disagreeable operation on account of the necessity of evaporating the excess of sulphuric acid, and experiments were made in which hydrochloric acid was substituted for sulphuric acid. To 5 gm. of a fine black loam soil in a platinum dish was added 25 cc. of fuming hydrofluoric acid (38 to 40 per cent), and the mixture evaporated slowly to dryness on the water bath. To the dry residue 15 cc. more of the acid was added and 25 cc. of hydrochloric acid (specific gravity 1.19) and the mixture again slowly evaporated. The latter process was repeated a second time, when complete decomposition of the mineral substance was obtained. In order to remove the hydrofluoric acid completely the residue was treated four or five times with hydrochloric acid in a boiling water bath, dried, transferred to a suitable container, heated with hydrochloric acid, filtered through an ashless filter, and carefully washed with hot water and a weak solution of hydrochloric acid. The filtered residue was then treated with more hydrochloric acid and nitric acid, and the filtrate was neutralized in the usual manner and found to contain aluminum, potassium, phosphorus, and traces of calcium.

The determination of the alkalinity and phosphoric acid content in the ash of foodstuffs, I. M. KOLTHOFF (*Chem. Weekbl.*, 13 (1916), No. 33, pp. 910-914).—The author briefly reviews the method described by Farnsteiner (E. S. R., 18, p. 1107) and indicates some disadvantages in its use.

For the determination of the alkalinity of the ash the following procedure is described: From 0.2 to 0.3 gm. of ash are treated with hydrochloric acid as in the method of Farnsteiner, filtered, and the filtrate neutralized with tenth-normal sodium hydroxid. A solution containing 0.25 gm. of neutral potassium oxalate and a solution containing the same amount of sodium chlorid are then

added, and the liquid is titrated with standard alkali, using phenolphthalein as an indicator.

Formulas for calculating both the alkalinity and the phosphorus content of the ash are included.

Comparative analytical data obtained in the examination of cocoa and pepper are also submitted.

**Pomace wines: Their composition and detection**, J. R. EOFF, JR. (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 723-726).—This article briefly discusses the manufacture of pomace wines and submits detailed analytical data of a number of white and red pomace wines, together with analytical data of two pure Catawba wines. The analytical data include determinations of alcohol by volume, reducing sugar as invert, nonsugar extract, glycerol, total acidity as tartaric, volatile acid as acetic, fixed acid as tartaric, free tartaric acid, cream tartar, combined tartaric acid, tannin and coloring matter, pentosans, volatile esters, and ash, and a complete mineral analysis of the ash.

**The nonprotein nitrogenous constituents of feeding stuffs**, H. S. GRINDLEY and H. C. ECKSTEIN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1425-1431).—An aqueous extract of alfalfa hay, timothy hay, blood meal, corn, and clover hay from which the water-soluble native protein was precipitated by colloidal ferric hydroxid was examined for its nonprotein nitrogenous constituents, and the analytical results are submitted in detailed tabular form.

The data show that the nonprotein nitrogenous constituents consist largely of the forms of nitrogen that result from the decomposition of proteins by hydrolysis. The sum of the amid, humin, free and combined amino, and free and combined acid-amid nitrogen represented in the nonprotein nitrogenous constituents form from 80 per cent in alfalfa hay to 94 per cent in blood meal of the nonprotein nitrogen.

It is deemed probable that "only a small part . . . of the nonprotein nitrogenous constituents of foods and feeding stuffs can in any way interfere with the application of the Van Slyke method for the determination of the chemical groups characteristic of the different amino acids of protein to the estimation of the free and combined amino acids and amids of feeding stuffs."

The so-called amid nitrogen of feeding stuffs is largely composed of free amino acids and peptid linkings. These forms, including the humin nitrogen, constitute about 53 to 63 per cent of the water-soluble nitrogen not precipitated by the colloidal ferric hydroxid. The free ammonia varied from 6.33 to 12.44 per cent of the water-soluble nitrogen not precipitated by the ferric hydroxid.

See also a previous note by Hart and Bentley (*E. S. R.*, 34, p. 501).

**A new sensitive method for the analysis of oils**, A. MAZZARON (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 8, pp. 583-594).—The author describes a new constant for use in the examination of oils which depends on the determination of the sulphur dioxid liberated after treatment of the oil with concentrated sulphuric acid.

The procedure consists of treating 20 cc. of the oil with 5 cc. of concentrated sulphuric acid (specific gravity 1.84), thoroughly shaking for about a quarter of a minute, and aspirating the liberated sulphur dioxid into a standard tenth-normal iodine solution, passing a current of air through the oil and acid mixture during the reaction. The reaction is carried out at 20° C., and when complete the iodine used is determined by titrating the excess with standard sodium thiosulphate. The number of cubic centimeters of tenth-normal iodine required to oxidize the sulphur dioxid liberated from 20 cc. of the oil is termed the sulphur-dioxid number of the oil.

The following figures for oils examined are submitted: Olive oil, 2.4; sesame oil, 49.5; cottonseed oil, 137.5; maize oil, 65; soy-bean oil, 223; rape oil, 15;

and peanut oil, 7. From comparative data submitted there appears to be no definite relation between the new sulphur-dioxid number and the Maumené number.

**I, Soy bean oil. II, Flax studies,** W. F. WASHBURN (*North Dakota Sta. Bul.* 118 (1916), pp. 35-48).—Part 1 of this bulletin contains tabulated analytical data of the percentage of crude ether extract, Hanus iodine number of the oil, saponification value at 25° C., refractive index at 25°, specific gravity at 15.5°, and the color of the oil of some 45 varieties of soy beans grown in a number of States under various climatic conditions. The samples examined included the crops of 1912, 1913, and 1914.

It is indicated, in general, from the data that no definite conclusions could safely be drawn as to the effect of climatic conditions on the content and quality of oil of different varieties of beans until the beans had been grown at least three years in the same locality.

Exposure tests to determine the value of the oil as a paint vehicle are in progress.

Part 2 contains data obtained from the examination of various strains of flaxseed, relative to the percentage content of moisture, protein, and oil and the drying quality of the oil. Further data of the percentage content of moisture and oil and iodine number, saponification number, refractive index at 25°, specific gravity, and acid number of the oil obtained from immature and high-grade flaxseed and from various strains of seed grown and harvested under the same conditions, and also from the seed of flax which had been allowed to become wet and injured to some extent after the harvest, are also submitted.

**The volatile oil of *Calycanthus occidentalis*,** C. C. SCALONE (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 729-731).—The oil distilled from the leaves and twigs of the plant possessed a greenish color, bitter taste, and camphoraceous odor. The following constants were determined: Density at 25° C., 0.9295; rotation, +7° 28'; index of refraction at 20°, 1.4713; free acid, 0.05 per cent; saponification value, 54.3; and acetyl value, 33.5. The oil was found to be soluble in all proportions in 90 per cent alcohol, and in from 15 to 16 volumes of 70 per cent alcohol by volume.

Seven fractions, the boiling points of which ranged from 154° to 220° and over, were obtained by fractional distillation. From the examination of these fractions the following percentage composition is given for the oil: Pinene (*d* and *l*), 8.3; cineol, 60.32; borneol, 9.21; camphor, ?; methyl salicylate, ?; linalyl acetate, 18.99; sesquiterpene alcohols, ?.

**Volatile oil of *Euthamia caroliniana*,** G. A. RUSSELL (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 7, pp. 1398-1402).—The oil examined was distilled from the fresh herb gathered just previous to the flowering stage. The yield obtained calculated with reference to the fresh material was 0.693 per cent. The oil was pale yellow in color and possessed a pleasant aromatic odor. The following physical and chemical constants were obtained: Specific gravity at 23° C., 0.8587; index of refraction, 1.4805; angle of rotation at 23°, -10° 48'; saponification value, 6.35 (equivalent to 2.1 per cent esters calculated as acetate); acetyl value, 25.3 (equivalent to 7.01 per cent of alcohol in the original oil); and ester number, 6.35. The oil was readily soluble in six volumes of 90 per cent alcohol and clearly soluble in an excess. Qualitative tests for phenols were negative, while a small amount of aldehydes was detected in the oil.

The original oil was fractionated into three fractions, and after first being saponified fractionated into six fractions. The analytical results obtained from an examination of these fractions are submitted in detail. It is indicated that the oil consists mainly of dipentene with a trace of pinene and possibly a small amount of limonene. Although the oil had been distilled and stored for 15

months, no free acids were present, but there was a small percentage of combined acids, probably formic and acetic. Of the 7.01 per cent of alcohol present 5.35 per cent was free and 1.66 per cent combined.

**Relative oil yield of Florida oranges,** S. C. HOOD (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 709-711).—From a study of the commercial possibilities of the manufacture of orange oil from Florida cull oranges a wide variation in the yield of oil of oranges under different climatic and cultural conditions was observed. "The oil content has not reached its maximum until the oranges are fully mature, but the oil is present in commercial quantities before the fruit are ready for harvest. The occurrence of heavy rainfall during the season of harvest will cause a considerable decrease in the oil content. The presence of rust mite does not decrease the percentage yield of oil of the mature fruit, but may show some effect early in the season."

**Studies on the extraction of rosin from wood.—I, Experiments using a petroleum solvent,** R. C. PALMER and H. R. BOEHMER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 695-701, figs. 7).

**A numerical expression for color as given by the Ives tint photometer,** O. KRESS and G. C. McNAUGHTON (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 8, pp. 711-714, figs. 8).—This article reports preliminary experimental data of a study to determine the possibility of using the Ives tint photometer as a measure of the progress of beating in paper milling and to observe the relation between the numerical expressions for depth of color as read from the instrument and the relation of the shades as noted by the eye.

The results obtained are expressed in graphic form.

## METEOROLOGY.

**The problems of agricultural meteorology,** G. AZZI (*Bol. Min. Agr. e Indus., Com. ed Lavoro [Rome], Scr. B*, 15 (1916), 11, No. 5-8, pp. 38-47).—This article discusses in some detail the elements necessary for the solution of the problems of agricultural meteorology, the organization and equipment of agricultural meteorological stations, methods, and forms to be used in reporting observations on the relation of plant growth to meteorological conditions, and methods of determining the critical period and forecasting the growth and yield of plants under different conditions of culture and climate.

**Climatological data for the United States by sections** (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 3 (1916), Nos. 9, pp. 222, pls. 2, figs. 4; 10, pp. 224, pls. 2, figs. 5).—These volumes contain, respectively, brief summaries and detailed tabular statements of climatological data for each State for September and October, 1916.

**Annual report of the Weather and Crop Service for 1915,** G. M. CHAPPELL (*Iowa Yearbook Agr.*, 16 (1915), pp. 593-643, figs. 3).—This report includes summaries of the monthly and weekly bulletins issued by the Iowa Weather and Crop Service in cooperation with the Weather Bureau of the U. S. Department of Agriculture. It shows that the average temperature for the State during the year 1915 was 47.8° F.; the average precipitation 39.53 in., or 7.56 in. above the normal; and the average snowfall 31.3 in.

"The striking features of the year were the remarkably cool summer, the frequency of showers during the crop season, the excessive cloudiness, the killing frost and freezing temperatures over the northeastern counties in August, and the fact that frost occurred at some place in the State every month of the year. The summer was the coolest of record, there being an average deficiency of temperature of 4.8° per day from May 1 to September 30, inclusive. Showers were frequent and many of them heavy, which delayed

corn planting and replanting, washed out many acres of corn, prevented or interfered with haying and harvesting, and ruined much of the hay and grain that had been cut. The cool, wet, and cloudy weather prevented the normal development of corn, and as a result two-thirds of the crop was not fully matured at the time of the first killing frost. The yield of practically all crops was, however, nearly up to the normal, but the quality of staple field crops was far below the normal, so that the year as a whole was one of the worst, if not the worst, in the history of the State."

The report also contains notes on fungus diseases in 1915, by L. H. Pammel, with special reference to the relation of the weather conditions to the prevalence and virulence of such diseases.

**Meteorological record, 1915** (*Montana Sta. Rpt. 1915, p. 260*).—A summary by months is given of observations at Bozeman, Mont., on temperature, precipitation, cloudiness, and winds. The highest temperature recorded was 90° F., August 30; the lowest, -17°, December 30. The mean temperature for the year was 41.68°. The annual rainfall was 24.72 in. The last killing frost in the spring occurred May 16; the first in the fall, September 14. The number of clear days was 144. The number of days with 0.01 in. or more of rain was 120. The prevailing direction of the wind was southeast.

**The phenology of Nova Scotia, 1915**, A. H. MACKAY (*Proc. and Trans. Nova Scotian Inst. Sci., 14 (1915-16), No. 2, pp. 133-140, fig. 1*).—This article gives the average dates (phenochrons) of various phenomena of wild life and of agricultural operations for each of the 10 biological regions of the Province and for the Province as a whole. These are based upon 350 of the best schedules of observations "made in the schools of the Province of Nova Scotia as a part of the nature study work prescribed."

[**Results of meteorological and soil temperature observations**], A. A. RAMBAUT (*Oxford: Humphrey Milford, 1916, pp. XV+215, pls. 4; rev. in Nature [London], 98 (1916), No. 2457, pp. 247, 248*).—This report gives the results of observations at Radcliffe Observatory, Oxford, on pressure, temperature, precipitation, wind, clouds, and other phenomena during 5 years—1911 to 1915—and on temperature at different depths in the soil during 12 years—1898 to 1910. The soil temperature observations were made by means of platinum resistance thermometers.

A comparison of the soil temperatures with the air temperatures shows clearly the retardation of phase as well as the diminution in amplitude in the passage of any oscillation of temperature from the surface to a depth of 10 ft. in the soil. There was found to be "a general falling off in the mean temperature amounting to about 2° during the period of 12 years over which the observations extend."

**Swedish meteorological observations, 1914** (*Met. Iakttag. Sverige (Observ. Mét. Suéd.), Met. Centralanst., 56 (1914), pp. XII+175*).—These are the usual meteorological summaries of observations made under the direction of the Central Meteorological Institute of Sweden.

**The distribution of precipitation in north Germany**, G. HELLMANN (*Sitzber. K. Preuss. Akad. Wiss., 1914, XXXVIII, pp. 980-990, figs. 2*).—The mean annual rainfall of the region during 20 years is shown to have been 638 mm. (25.1 in.), the lowest mean at any point being 416 mm. and the highest 1,700 mm.

**Thunder and hail in the region of Paris**, A. ANGOT (*Compt. Rend. Acad. Agr. France, 2 (1916), No. 31, pp. 912, 913*).—The record of the occurrence of thunder and hail in this region from 1874 to 1913 is given. This indicates that there is no relation between hail and electric phenomena.

**The climate of western and equatorial Africa**, R. CHUDEAU (*Ann. Géogr. 25 (1916), No. 138, pp. 429-462, figs. 12*).—This region is divided into three

climatic zones, of which the characteristic conditions of physiography, temperature, pressure, winds, humidity, evaporation, and rainfall are described, with a brief note on tornadoes and a short description of the more general climatic characteristics of the region.

The correlation of rainfall and the succeeding crops with special reference to the Punjab, S. M. JACOB (*Agr. Jour. India, Indian Sci. Cong. No., 1916, pp. 86-102, pls. 11*).—Studies of the relation between the July, August, September, and October rainfall and area sown to crops and between the September-March rainfall and the yield of crops are reported. These studies were made as a necessary preliminary to the successful forecasting of the total crop production. The studies are based on 30 years' (1886 to 1915) observations on irrigated wheat, unirrigated wheat and gram, and all other unirrigated crops. The general outcome of the application of the various correlations observed was an error of prediction for the area of irrigated wheat of 5.6 per cent of the mean; of unirrigated crops 9 per cent of the mean.

The Kincer method of prediction of yield of cotton, based on the assumption that the best conditions are the normal ones (E. S. R., 33, p. 117), was applied to unirrigated wheat. "The weighted rainfall in each month was added together, and a coefficient of benefit *B* obtained, and this was correlated with the area of unirrigated wheat for 1900 to 1915. The correlation is  $-0.91$ , even higher than Kincer's figure of  $0.88$ . The formula giving the percentage of failure in terms of the coefficient *B* is  $K=24.2-0.35B$ ." The agreement of the values shown by this formula is, in the opinion of the author, very good and "affords a posteriori justification of the hypothesis. The introduction of suitable corrections for other climatic factors, such as temperature, sunshine, evaporation, precipitation in the form of dew, wind, and the like would improve the prediction still further."

The climatic control of Australian production, G. TAYLOR (*Commonwealth Bur. Met. Aust. Bul. 11 [1916], pp. 32, pls. 7, figs. 10; rev. in Scot. Geogr. Mag., 32 (1916), No. 10, p. 487*).—The distribution and production of cattle, sheep, and wheat with reference to climate is discussed. This seems to depend mainly upon the rainfall, particularly in the case of wheat. Temperature is also a limiting factor in the case of wheat, but less so in the case of cattle and sheep.

It is shown that the most intensive cattle production occurs in the eastern and wetter (over 20 in. of annual rainfall) parts of the country, and that the greatest sheep production occurs in areas having from 15 to 20 in. of rainfall. The relation of wheat growing to temperature and rainfall in the different Australian States is shown in the following table:

*Relation of temperature and rainfall to wheat production in Australia.*

Wheat belt.	Temperature.			Rainfall.		
	Annual.	April-October.		Annual.	April-October.

**SOILS—FERTILIZERS.**

The present status and future development of soil classification, G. N. COFFEY (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 4, pp. 239-243).—An outline of the present status of soil classification is given, it being pointed out that "the tendency at the present time is to develop a system of classification based upon actual differences in the character of the soil itself. . . . For the working out of such a system in detail it is essential to have a knowledge not only of the peculiarities and differences in soils but also the relative importance of these in terms of crop production."

Field operations of the Bureau of Soils, 1913 (fifteenth report), M. WHITNEY ET AL. (*U. S. Dept. Agr., Field Operations Bur. Soils, 1913, pp. 2438, pls. 43, figs. 62, maps 54*).—This report contains a general review of the field operations of the Bureau of Soils during 1913 by the chief of the Bureau, together with detailed accounts of 53 surveys which have already been noted in the Record. During the calendar year 1913 a total area of 31,676 square miles, or 29,272,640 acres, were surveyed and mapped in detail, making the total area surveyed and mapped up to the end of that year 315,794 square miles, or 202,108,160 acres. There were also conducted reconnoissance surveys covering an area of 15,917 square miles, or 10,186,880 acres.

[Soil analyses] (*Biol. Agr. [São Paulo], 17. ser., No. 4-5 (1916), pp. 337-344*).—Chemical analyses of 79 samples of different soil types of the State of São Paulo, Brazil, are reported and discussed.

Water penetration in the gumbo soils of the Belle Fourche Reclamation Project, O. R. MATHEWS (*U. S. Dept. Agr. Bul. 447 (1916), pp. 12, figs. 4*).—Studies of the rate of flow of water in very heavy clay gumbo soils of residual origin when loose and saturated and when wet and dry under field conditions are reported.

These soils are said to be highly productive, with large water capacity, but the large content of clay makes them subject to extreme changes in volume with changes in water content. Three-in. samples of the soil to a depth of 24 in. were studied, and it was found that the time taken for an inch of water to pass through 3-in. layers of loose saturated soil was four hours for the first-foot sample and 12 hours for the second-foot sample. It was further found that "on a dry soil, penetration takes place rapidly to a depth of about 2 ft. because of the cracked condition of the soil near the surface. After the layer of easily penetrated soil becomes wet, it becomes so swollen and compact that it is nearly impervious, and further water movement is very slow. The fact that moisture can move only very slowly in the wet surface soil would make it necessary to run water over the soil for a very long time in order that any considerable portion might be absorbed. This is not practicable, for the experiment with a dry subsoil showed that water from the surface penetrated almost as deep in a few minutes as it did in 10 days."

The freezing point method as a new means of determining the nature of acidity and lime requirement of soils, G. J. BOYRUCOS (*Michigan Sta. Tech. Bul. 27 (1916), pp. 56, figs. 18*).—The freezing point method was tested with a large number of soils of different kinds under a variety of conditions to determine their lime requirement, as well as to study the absorption by the soil of sodium, potassium, and ammonium from solutions of potassium, sodium, and ammonium hydroxids; and the effect of acids and acid salts and of soluble salts upon the lime requirement of soil.

The method as used consists of adding to 2 gm. of soil 10 cc. of water and determining the lowering of the freezing point. Then to this mixture are added various amounts of  $\text{Ca}(\text{OH})_2$  until there occurs a change in the magni-

tude or direction of the freezing point depression. The method is based upon the following principles: (1) The freezing point depression of a soil containing a soluble acid or acid salt decreases upon adding various quantities of  $\text{Ca}(\text{OH})_2$  up to a certain point and thereafter increases with further additions. This point is considered to be the point of neutralization of the acid or acid salt and of the saturation of the soil for lime. (2) The freezing point depression of a soil containing neither a soluble acid nor an acid salt but possessing an absorptive power for lime remains constant as  $\text{Ca}(\text{OH})_2$  is added up to a critical point and thereafter rises with further additions. The critical point is considered to be the saturation of the soil for lime. (3) The freezing point depression of a soil already alkaline and saturated with bases starts to rise almost immediately upon the addition of a small amount of  $\text{Ca}(\text{OH})_2$ .

The results showed that the amount of lime taken up by soils varied greatly. The freezing point method gave much higher lime requirements than the Veitch method, and appeared to indicate the true maximum lime requirement of soils. "The absorption curve of the mineral soils signifies that the  $\text{Ca}(\text{OH})_2$  is taken out of solution and is rendered inactive as far as the freezing point depression is concerned. The substances which accomplish this are in the solid phase. . . . The absorption curve also indicated that there is no basic exchange in soils, when a hydrate is employed, until the soil is satisfied or saturated with the base."

Most of the few peats tested gave evidence of acidity and took up calcium, potassium, sodium, and ammonium hydroxids in equivalent amounts.

"When a soil ceased to take up one base it took up very little if any of another base, or if it did it released a corresponding amount of the one with which it was already saturated. On the other hand, when a soil still absorbed one base it absorbed a corresponding quantity of another. The addition of acids and acid salts increased the lime requirement of soils. The magnitude of the increase was approximately equal to the amount of lime required to neutralize the quantity of the acid or acid salt added. . . .

"When a soil was treated with an excess of acid and then washed, the lime requirement was also increased, but the results plotted into an absorption curve. When a soil which showed a high lime requirement was treated with an excess of acid the clear supernatant liquid failed to give an acid curve, indicating that it contained very little if any acid. The litmus paper tests showed that it was very nearly neutral. The sediment, however, gave an acid curve, signifying that it contained a considerable amount of acid. . . . When this sediment was washed with water, however, the acid curve could no longer be obtained, showing that the acid was washed away." The same was observed with salts in solution.

"All soluble salts increased the lime requirement of soils, but the magnitude of the increase was greater in the case of the neutral salts than of the acid phosphate salts."

The conclusion is drawn that "the presence of soluble acids, or acid salts, in the mineral soils under favorable natural conditions is only temporary, if ever present, and never permanent. The acidity or lime requirement of soils, therefore, seems to be due mainly to the insoluble acids of the soil, the silicic acid, silica, acid aluminosilicates, and perhaps to the insoluble organic matter. There appears to be then practically no active acidity in the mineral soils, but only negative. Exceptions to these general statements are probably very few. In the peats and mucks, however, the formation of organic acids is probably quite rapid, and consequently these soils, as indicated by the data, may contain permanent active acidity as well as permanent negative acidity."

The organic phosphorus of soil, R. S. POTTER and T. H. BENTON (*Soil Sci.*, 2 (1916), No. 3, pp. 291-298).—A method proposed for determining the total organic phosphorus content of soil is described, and experiments conducted at the Iowa Experiment Station on the content of organic phosphorus in a fallow orchard soil are reported.

It was found that "while the method can not be said to give an absolute knowledge of the organic phosphorus content of soil, it at least gives comparative results. . . . As a result of the work done so far, it can be definitely stated that a large part of the phosphorus of the soil is organic in nature."

A list of 18 references to literature bearing on the subject is appended.

The effects of certain organic compounds on plant growth, M. J. FUNCHESS (*Alabama Col. Sta. Bul.* 191 (1916), pp. 103-132, pls. 8).—Two years' pot culture experiments with oats and corn are reported to determine whether the results obtained by adding fertilizers and lime and certain organic compounds, including coumarin, vanillin, pyridin, quinolin, dihydroxystearic acid, and pyrogallol, to heavy, sticky red clay, unproductive sandy soil, and to productive and unproductive sandy loam soils at rates of 100, 250, 500, and 1,000 parts per million of dry soil would parallel those obtained in solution cultures.

It was found that lime, carbon black, and pyrogallol, which have been shown to remove the toxic properties of a poor soil extract, were unable to increase the crop yield when added to the poor soils used. "On the other hand, the addition to soils of such toxic compounds as vanillin, coumarin, dihydroxystearic acid, pyridin, or quinolin, failed to increase greatly the infertility of the infertile soils used. The application of such compounds in ratios as great as 1,000 parts per million of dry soil decreased the yields in some cases where the crop was planted on the same day that these heavy applications were made. But when these compounds had been in the soil for a few months . . . little or no toxic effects were to be found. Indeed, the nitrogenous compounds had a beneficial effect in all cases reported, though there was evidence that these may be harmful for a short time after the applications are made. This constitutes good evidence that rapid chemical or biochemical transformation of these compounds into beneficial or inert forms occurs in unsterilized soils under the conditions of these experiments. Slight injury to oats was apparent in most of the heavy treatments of pyridin and quinolin during the first weeks of growth; but this injurious action disappeared, and the pots so treated usually produced crops which compared favorably with those produced by the nitrate-treated pots."

The addition of potassium and phosphorus greatly increased the beneficial effects of pyridin and quinolin. This action is not regarded as an antitoxic action, as these two mineral elements greatly increased the effect of asparagin, nucleic acid, and sodium nitrate, none of which is toxic to plants.

It is pointed out further that "had these experiments been terminated when the plants were only 15 days old . . . both pyridin and quinolin would have been found to be harmful, while . . . vanillin and coumarin would have been recorded not injurious. Neither of the latter showed injury to oats during the first few days of growth; only in the later stages could their effect be noted, and that effect was a simple retardation of growth."

The results show "that solution culture and soil culture experiments fail to agree," and the author concludes that "soil fertility problems can not be solved by means of short-time solution culture studies."

Physiological balance of nutrient solutions for plants in sand cultures, A. G. McCALL (*Soil Sci.*, 2 (1916), No. 3, pp. 207-254, pl. 1, figs. 8).—Experiments conducted at the Maryland Experiment Station are reported on the relative growth rates of young winter wheat seedlings when grown in a substratum

of washed quartz sand, supplied with a nutrient solution having an initial total concentration of 1.75 atmospheres maximum osmotic pressure, but with 36 different proportions of potassium phosphate, calcium nitrate, and magnesium sulphate. "The total growth period was 24 days, during which time the total water loss from each culture was determined at the end of each 3-day interval. At the end of the growth period the cultures were compared with respect to (1) dry weight of tops, (2) dry weight of roots, (3) total water loss, (4) water requirement per gram of dry tops, (5) water requirement per gram of dry roots, and (6) the ratio of the weight of tops to dry weight of roots."

It was found that "the graphs representing the growth rate of young wheat plants for three preliminary series show a region of optimal growth rate lying between the concentrations 1 and 2 atmospheres. With the initial total concentration about 1.75 atmospheres, the nutrient solution that produced the greatest dry weight of tops also produced the greatest dry weight of roots. This solution is characterized by having 0.2 of the total osmotic concentration derived from  $\text{KH}_2\text{PO}_4$ , 0.7 from  $\text{Ca}(\text{NO}_3)_2$ , and 0.1 from  $\text{MgSO}_4$ .

"A general comparison of the results from this sand-culture series with solution cultures (Shive's) grown from the same lot of seed but at a different time period brings out [that] (1) the average dry weights of both tops and roots were decidedly greater for the plants grown in the sand than for those grown in the solutions; (2) the results obtained in the solution-culture series, having a total osmotic concentration of 0.1 atmosphere, are more nearly like those from the sand series than are the results secured from the more concentrated solution series (1.75 atmospheres), in which the solutions were of the same total osmotic concentration as that employed for the sand cultures; and (3) there is a marked difference between the solutions producing the best development of plants in sand and those giving the best growth in the solution cultures with respect to the osmotic proportions of the three salts employed. A comparison of the results from these two series, the one grown in solution and the other in sand cultures, furnishes evidence for the conclusion that selective adsorption plays an important rôle in bringing about the observed physiological differences. The sand-culture solutions giving low yields of tops are characterized by a wide range in the Mg/Ca ratio, a very wide range in the Mg/K ratio, and a narrow range in the Ca/K ratio value. The solutions giving high yields of tops show a narrow range in the Mg/Ca ratio and a comparatively wide range in both the Mg/K and Ca/K ratio values. The data presented support the conclusion of earlier workers to the effect that the total transpirational loss from a plant culture is approximately proportional to the growth made by the plants during the period of time considered.

"The water requirement per gram of dry tops varies considerably with the different proportions of the component salts. It appears that low water requirement for tops is associated with a low partial osmotic concentration of monopotassium phosphate, and that high water requirement is associated with high partial concentrations of both magnesium sulphate and monopotassium phosphate. The water requirement per gram of dry roots is much higher than the same value for tops. A consideration of the ratio of tops to roots brings out the fact that in every instance a high water requirement corresponds to a high ratio of tops to roots. Good growth of tops was found to be associated with a high osmotic ratio of  $\text{Ca}(\text{NO}_3)_2$  to  $\text{MgSO}_4$  and poor growth of tops with a low value of this ratio."

A list of 46 references to literature bearing on the subject is appended.

Preliminary investigations in comparison of field with laboratory experiments in soil biology, G. P. KOCH (*Soil Sci.*, 2 (1916), No. 1, pp. 87-92, fig. 1).—

Preliminary investigations conducted at Rutgers College comparing field and laboratory experiments in soil biology and using loam, silt loam, and sandy soil are reported.

It was found that "biological experiments (e. g., in ammonification) can be successfully carried out in the field. As a rule, a greater amount of organic matter seems to be ammonified in the laboratory tests than in the field. Nitrogen fixation and nitrification studies in the field are greatly interfered with by rains. The nitrogen content of the soil varies considerably, even over a comparatively small area."

Sources of error in soil bacteriological analysis, H. C. LINT and D. A. COLEMAN (*Soil Sci.*, 2 (1916), No. 2, pp. 157-162, fig. 1).—Experiments conducted at Rutgers College with sandy loam and clay loam soils, using dried blood as organic matter, to determine the influence on ammonification of time and method of mixing the soil with organic matter, are reported.

It was found that mixing the organic matter with the soil for 30 seconds showed a larger ammonia accumulation than where the mixing occupied only 15 seconds. The experimental error of the average for 30-second mixings was smaller than that obtained for 15-second mixing periods. In general, there was not so great a difference between the two periods of mixing with the shaker as was the case where the spatula was used. The averages obtained with the shaker were larger than where the spatula was used to stir the organic matter into the soil. A comparison of the moist and the air-dry soil showed a larger accumulation of ammonia in the case of the former soil. "In general, the experimental error of the averages of the soils prepared in the shaker is smaller than that obtained with the spatula, which bespeaks a narrower variation in the duplicate determinations."

A study of the action of carbon black and similar absorbing materials in soils, J. J. SKINNER and J. H. BEATTIE (*Soil Sci.*, 2 (1916), No. 1, pp. 93-101, pls. 3).—It is pointed out that finely divided carbon is a good agent for physiologically purifying distilled water and certain poor soil extracts, and that by its absorptive qualities it improves the solution as a medium for plant growth. A test made by mixing carbon black with poor soils failed to effect an improvement, as the carbon, even though it might have had an absorptive action, would itself be intermingled with the soil and be in contact with the plant roots.

"With carbon incased in porous earthenware pots buried in soil, the growth of grass, clover, and cowpeas was improved when growing in a poor unproductive soil in the greenhouse. On benches in the greenhouse a soil which contained salicylic aldehyde and other organic compounds was improved for the growth of string beans by the absorptive action of carbon buried in porous tubes in the soil. In an experiment with string beans and lettuce in greenhouse benches a soil made poor by the addition of salicylic aldehyde and vanillin was improved in productivity by the action of carbon incased in porous tubes. In a two years' field experiment carbon, charcoal, and chalk when put in porous tubes and buried in the plats caused a good increase in growth of cowpeas.

"The beneficial action of carbon and other absorbents may be attributed to its removing something from the soil solution which is harmful to plants. The soil moisture passing through the carbon in its process of moving downward and upward in the soil would be robbed of any such material. Soils which contain soluble organic substances harmful to plants would be improved for crop growth."

Five references to literature bearing on the subject are appended.

Soil fungi and their activities, S. A. WAKSMAN (*Soil Sci.*, 2 (1916), No. 2, pp. 103-155, pls. 5).—Experiments conducted at the New Jersey Experiment

Stations with garden, orchard, meadow, and forest soils, gravelly loam, a medium loam containing 48 per cent iron, an adobe soil from Oregon, and different California soils are reported to determine the numbers and activities of soil fungi.

It was found that the fungi found in all the soils studied represent a group of organisms in numbers large enough to warrant a conclusion that they probably play an important part in the fertility of the soil. No distinct difference was observed between the species of fungi found in cultivated soils and those in uncultivated soils, though each soil seemed to have a more or less characteristic fungus flora; for example, the cultivated orchard soil, has a great abundance of Mucorales, while the forest uncultivated soil, has an abundance of Penicillia and Trichodermae. The numbers of fungi decreased rapidly with depth, so that at 12 to 20 in. below the surface very few fungi were found, the largest numbers occurring within the upper 4 in. of soil. As to the species, no distinct differences among the organisms were found with the different soil depths, except that in the subsoils of most of the soils studied, *Zygorhynchus vuilleminii* was found to be present, often as the only organism, when soil was inoculated directly upon sterile medium.

“Over 100 distinct species of fungi were isolated from the soil, belonging to 31 genera, many of the species being isolated from several of the different soils. Many pathogenic fungi, such as different Fusaria, Alternaria, Aspergilli, Coniothyrium, and others, have been isolated from the soil. . . .

“The study of the physiological activities of the fungi pointed out the fact that they do not play a very great, if any, part in the fixation of atmospheric nitrogen, but they do prove to be able to decompose organic matter rapidly and liberate ammonia, under laboratory conditions. Many of them prove to be strong decomposers of cellulose, though fewer of them hydrolyze starch.”

A list of 125 references to literature bearing on the subject is appended.

**Azotobacter in Hawaiian soils**, P. S. BURGESS (*Soil Sci.*, 2 (1916), No. 2, pp. 183-192).—Experiments conducted at the Hawaiian Sugar Planters' Station on the azotobacter content of 30 sugar cane soils from the islands of Oahu, Hawaii, Maui, and Kauai, as indicated by their ability to fix nitrogen in manure solutions are reported.

Only 5 soils were noted which failed to show azotobacter growth in solutions. “In these cultures some fixation is recorded which indicates that probably certain Clostridium forms are also fairly prevalent here.” Four different forms of Azotobacter were isolated in pure culture, namely, *A. chroococcum* var., *A. vinelandii* n. var.? *A. vinelandii* var., and “B 29?”.

Two references to literature bearing on the subject are appended.

**Environmental factors influencing the activity of soil fungi**, D. A. COLEMAN (*Soil Sci.*, 2 (1916), No. 1, pp. 1-65, figs. 10).—Experiments conducted at Rutgers College with sandy loam and clay loam soils on the influence of organic matter in the form of dried blood, cottonseed meal, soy-bean meal, vetch, and rye; of mechanical and chemical composition of the soil, moisture, and temperature on the activity of soil fungi; and experiments on the associative action of soil fungi and soil bacteria are reported. It was found that the type of soil, the quality of the organic matter, definite combinations of soil and organic matter, mechanical composition, and moisture content of soil are important factors in regulating the activities of the organisms tested.

**The effect of time and depth of cultivating a wheat seed bed upon bacterial activity in the soil**, P. L. GAINES (*Soil Sci.*, 2 (1916), No. 2, pp. 193-204, figs. 4).—This article reports studies conducted at the Kansas Experiment Station on nitrate and ammonia formation in soil, described in a report of previous experiments by Call (E. S. R., 33, p. 217) on the effects of different methods

of preparing a seed bed for wheat on yield, soil moisture, and soil nitrates. Plats were selected which were representative of the extremes in treatment in the previous experiments.

It was found that "the differences in nitrate content reported by Call can not be attributed to a difference in the bacterial content. Some nonbiological condition existing in certain plats, under field conditions, prevents the normal activity of the bacterial flora. Among the factors controlling bacterial activity the available moisture probably plays a paramount rôle."

Four references to literature bearing on the subject are appended.

**Studies on the activity of soil protozoa**, G. P. KOCH (*Soil Sci.*, 2 (1916), No. 2, pp. 163-181, fig. 1).—In a further contribution (*E. S. A.*, 34, p. 422) experiments conducted at Rutgers College with sandy loam and clay soil to determine the influence of moisture content, organic matter, and physical properties of soil on the presence of protozoa in soils in the active state are reported.

It was found that "the direct examination of the soil under the microscope for a period of 15 to 20 minutes (taking three or four samples), gives a fair indication as to the relative extent of active protozoa in the soil. Practically all of the protozoa as found in the soil can be observed under the low power of the microscope.

"The addition of organic matter to the Sassafras sandy loam soil encouraged a greater protozoan development than where none had been added. Additions of dried blood to the Penn clay loam soil increased the number of active protozoa but very little, while cow manure had no effect on the protozoan activity of this soil.

"Increasing the porosity and aeration of the soils by the addition of sand did not increase the number of motile protozoa.

"In the Sassafras soil to which cow manure had been added flagellates were noted on the first day, while with the other samples they were not seen until the second or third and, in some cases, the fourth day. The maximum numbers were recorded on the fourth and sixth days, after which there was a marked decrease, so that on the twenty-first and twenty-eighth days practically none were found to be in the active state. This would indicate that the destructive ability . . . would be present for only a limited period, namely, the early stages of organic decomposition.

"Flagellates were the first protozoa to excyst; later, on the third and fourth days, small ciliates appeared. On the fourteenth, twenty-first, and twenty-eighth days small ciliates were more numerous than flagellates. With these soils the largest number of protozoa was recorded where the moisture was highest. The Penn clay loam soil seemed to be a very undesirable medium for protozoa, as very few of these organisms were noted in any of the samples compared with those found in the Sassafras soil.

"At the lowest moisture content (one-third of the optimum), protozoa did not become active. With these soils moisture seemed to be the primary limiting factor which determined the presence or absence of active protozoa.

"With one exception, no correlation between the presence of protozoa in the active condition and the numbers of bacteria could be seen. Increased numbers of bacteria were observed irrespective of the presence or absence of living protozoa. On the fourteenth day in the soils, even where no protozoa were found in the active condition, there was a great decrease in bacterial numbers.

"Inasmuch as the numbers of protozoa in comparison with the bacterial numbers are so small, even in the presence of such abnormal quantities of organic matter as were used, it hardly seems that they would be of very great importance in agricultural practices."

A list of 19 references to literature bearing on the subject is appended.

The increase of nitrogen in fermenting manures, W. E. TOTTINGHAM (*Jour. Biol. Chem.*, 24 (1916), No. 3, pp. 221-225; *abs. in Chem. Abs.*, 10 (1916), No. 14, p. 1901).—Experiments conducted at the Wisconsin Experiment Station are reported on the increase in nitrogen content of a mixture of fresh cow and horse manure mixed in the ratio of 2:1, with and without fine and coarse chopped wheat straw at rates of 0.5 and 6.25 kg. per 6.25 kg. of manure.

After four weeks it was found that there was an appreciable gain of nitrogen in the straw-littered manures. Further tests of the manures for nitrogen fixation in mannite solution showed that "the manures contain nitrogen-fixing organisms of considerable activity. As their activity was greatest in the fermentation experiments in those manures which were mixed with straw, the latter material appears to be an important source of energy for the organisms."

The action of barnyard manure and commercial fertilizers, P. WAGNER (*Arb. Deut. Landw. Gesell.*, No. 279 (1915), pp. 544).—This is a report of results of a series of cooperative experiments extending from 4 to 14 years. They included 20 series of rotations varying in length from 3 to 14 years. The series were divided into two groups, one with commercial fertilizers alone and the other with the addition of manure. The soils varied from sand to clay loam. The crops grown included potatoes, beets, winter rye, winter wheat, barley, oats, and clover. The general plan and methods of conducting the experiments were substantially the same as in previous experiments reported by the author. Experimental data are given in detail and carefully summarized and analyzed.

Among the conclusions reached are that \$100 expended for fertilizers produced an average increase worth \$210 in the series of experiments with commercial fertilizers alone and \$190 in the series in which manure and fertilizers were combined.

It was found to be necessary to apply phosphoric acid in the form of Thomas slag in great excess, namely, six to seven times as much as the increased yields contained in order to meet the crop requirements for this constituent. Only 18 per cent of the citric acid-soluble phosphoric acid in the slag applied was recovered in the crops in the course of three rotations on a soil very deficient in phosphoric acid. The assimilation of the phosphoric acid increased from year to year with continued applications of slag, reaching its normal level in about seven years. The phosphoric acid of manure was much more quickly utilized by plants than that of Thomas slag, the ratio being 100:181 in the first rotation and 100:172 in the second.

Of the potash applied in form of potash salts 34 per cent was utilized in the first rotation and 51 per cent in the course of the two rotations. The author concludes from these and previous experiments that not more than 60 per cent of the potash applied is likely to be utilized under any circumstances in practice. The potash in manure appeared to be somewhat more quickly utilized by plants than that of Stassfurt salts. For example, 34 per cent of the potash of the Stassfurt salts as compared with 40 per cent of the potash of manure was utilized in the first rotation. On the other hand, the corresponding figures for the second rotation were 51 and 52 per cent.

About 60 per cent of the nitrate nitrogen applied was utilized by the crops, but only 25 per cent of the manure nitrogen was utilized in the first rotation.

The average figures for the utilization of the fertilizing constituents of manure and commercial fertilizers by crops may be summarized in brief as follows:

*Assimilation of fertilizing constituents of manure and fertilizers by crops.*

	Phosphoric acid.	Potash.	Nitrogen.		Phosphoric acid.	Potash.	Nitrogen.
Sandy soils:	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	Loam soils:	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Manure.....	25	58	21	Manure.....	25	53	19
Fertilizers.....	45	76	69	Fertilizers.....	36	70	71

The average composition of 73 samples of moderately rotted yard manure used in these experiments was phosphoric acid 0.35 per cent, potash 0.55 per cent, and nitrogen 0.5 per cent. The author holds, contrary to B. Schulze's view, that the fertilizing value of manure, as of commercial fertilizers, depends upon its percentage content of plant food (E. S. R., 26, p. 424). As with other fertilizers, however, conditions of soil and season must be favorable for the best results. Moreover, it appears that manure contains too little nitrogen to make it possible to secure the best use of the phosphoric acid and potash which it contains, crops grown with manure alone being oversupplied with the latter. Therefore the true value of the plant food of manure is not secured by its exclusive use. In no case did manure alone give as high yields as manure with fertilizers, the average relation of yields in all experiments being 1:1.3. Maximum crops, especially of cereals, were often obtained with fertilizers alone, and in some cases the results were higher than with fertilizers and manure combined. On the other hand, in the case of hoed crops, such as potatoes and beets, better results were uniformly obtained with fertilizer and manure combined.

The ratios of grain to straw with the different treatments were as follows:

*Ratios of grain to straw with different fertilizer treatments.*

Kind of crop.	Parts of grain to 100 parts straw.		
	Check.	Complete commercial fertilizer.	Complete fertilizer and manure.
Oats.....	63	58	55
Winter rye.....	52	48	48
Winter wheat.....	53	50	49
Barley.....	78	77	77

The percentage contents of phosphoric acid, potash, and nitrogen in the crops grown in the experiments are given. These show that the composition of the grain of cereals is quite constant, while that of straw and hoed crops generally is very variable. The author concludes that such data can be used only as a basis for further tests of the fertilizer requirements of plants.

The results of these experiments indicate that if sodium nitrate is used exclusively the amount applied must be increased from year to year, and, furthermore, that the exclusive use of commercial fertilizers, as a rule, accelerates the loss of nitrogen from the soil, while the use of manure with fertilizers not only prevents loss but brings about a marked increase in the nitrogen content of the soil.

Summarizing the results of 37 rotations it is shown that of 100 parts of phosphoric acid and of potash in the soil soluble in hydrochloric acid, 0.64 parts and 0.79 parts, respectively, were used by plants, and of 100 parts of total nitrogen in the soil 1.09 parts were utilized by plants.

**Experiments with humogen and heated peat**, C. T. GIMMINGHAM (*Nat. Fruit and Cider Inst., Long Ashton [Eng.], Rpt. 1915, pp. 110-113*).—Pot experiments with tomatoes on a stiff loam soil to compare bacterized peat and heated peat, when added at rates of 1 lb. 4 oz. and 1 oz. to 20 lbs. of soil, with stable manure, stable manure and bacterized peat extract, stable manure and heated peat extract, and stable manure and sodium nitrate are reported.

It was found that large doses of both bacterized and heated peat gave large increases over the control. As good results were obtained, however, with ordinary treatment for tomato culture. "There seems no reason to attribute the increase in yield to anything more than ordinary manurial properties. . . . One oz. of humogen has apparently given as good results as 4 oz., but the increase over the yield from soil only is not very great in any case and is within the limits of experimental error. . . . The treatment with the water extract of humogen or peat has given no increase whatever."

**Absorption and washing out of nitrogen in fertilizing with ammonium sulphate**, C. H. VAN HARREVELD-LAKO (*Arch. Suikerindus. Nederland. Indië, 24 (1916), No. 6, pp. 177-204, fig. 1; Meded. Proefstat. Java-Suikerindus., 6 (1916), No. 2, pp. 17-44, fig. 1; abs. in Chem. Abs., 10 (1916), No. 14, p. 1902*).—The work of others bearing on the subject is briefly reviewed, and experiments are reported on the absorptive power for ammonia of Java sugar-cane soils to which 0.2-normal ammonium sulphate was added at the rate of 50 cc. per 50 gm. of dry soil.

It was found that the absorption coefficient of the soils for ammonia varied between 15 and 219 and in most cases was above 140. Soils with a high absorptive power lost less ammonia through washing than those with low absorptive power. If the absorption coefficient is between 80 and 140 there is thought to be little danger of ammonia loss by washing. As a rule a low absorption coefficient of soil accompanied a coarse texture and vice versa. There were, however, exceptions to this rule. When equal amounts of ammonium sulphate of the same concentration were added to different quantities of soil, the amount of increase in ammonia absorption decreased as the quantity of soil used increased. The presence of humus in the soil increased the absorptive power for ammonia. With reference to the exchange of ammonia for calcium, magnesium, potassium, and sodium it was found that the total sum of equivalents of the latter equaled the equivalent of the absorbed ammonia.

**Phosphate rock in 1915**, W. C. PHALEN (*U. S. Geol. Survey, Mineral Resources of the United States, Calendar Year 1915, pt. 2, pp. 227-244, pl. 1, fig. 1*).—This report deals with the production, sale, imports, and exports of phosphate rock during 1915, describes domestic phosphate reserves, gives notes on the conservation of phosphate rock, describes processes for making soluble phosphates, and contains an article by W. B. Hicks on simple tests for phosphate.

"The quantity of phosphate rock mined in 1915 was 1,935,341 long tons. Compared with the quantity mined in 1914 . . . this was a decrease of about 27 per cent. In Florida the decrease amounted to nearly 31 per cent; in Tennessee it was about 9 per cent; in South Carolina, 31 per cent; and in the Western States, 25 per cent. No rock was reported mined in Kentucky in 1915. Stocks on hand at the close of 1915 showed an increase for the entire country amounting to nearly 11 per cent. In Florida the increase amounted to 14 per cent; in Tennessee it was 6 per cent; in South Carolina there was a decrease of 34 per cent." "The phosphate rock marketed in the United States in 1915 amounted to 1,835,667 long tons, valued at \$5,413,449. Compared with the pro-

duction of 1914 . . . this was a decrease . . . of nearly 33 per cent, and in value . . . nearly 44 per cent."

**The conservation of phosphate rock in Tennessee**, W. C. PHALEN (*Resources Tenn.*, 6 (1916), No. 4, pp. 193-216, figs. 5).—This article deals with the occurrence and distribution of phosphate deposits in Tennessee and describes specific examples of modern ways and means of conserving phosphate rock as practiced in the Mount Pleasant, Tenn., field.

**The limestones of the Canterbury Province**, R. SPEIGHT (*Jour. Canterbury Agr. and Past. Assoc.*, 3. ser., 4 (1916), pp. 5-16, figs. 7).—This article describes the occurrence, distribution, and composition of the limestones of the Province in New Zealand. Analyses of three different limestones from the Province show calcium carbonate contents of 88.64, 82.26, and 67.6 per cent.

**Sodium chlorid as a fertilizer**, P. BOLIN (*K. Landtbr. Akad. Handl. och Tidskr.*, 55 (1916), No. 5, pp. 368-376; *Meddel. Centralanst. Försöksv. Jordbruksområdet*, No. 131 (1916), pp. 3-11; *abs. in Chem. Abs.*, 10 (1916), No. 17, pp. 2268, 2269).—Field experiments with sugar beets and potatoes are reported, the results of which are taken to indicate that common salt when added to the fertilizer used did not decrease the dry matter in the crop. On the other hand, it is concluded that the amount of dry matter is no less with sodium chlorid than with potassium chlorid, but is increased at about the same rate by both salts.

**Fertilizer experiments with manganese dioxid used on grain**, R. RICCI and G. BARBERA (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 9, pp. 677-689; *abs. in Chem. Abs.*, 10 (1916), No. 18, p. 2382).—Experiments with wheat on the use of manganese dioxid alone, with sodium nitrate, and with ammonium sulphate at the rate of 300 lbs. per hectare (about 121 lbs. per acre) are reported.

The greatest yield of grain was obtained where manganese dioxid was used with sodium nitrate, and the yield with manganese dioxid alone was next. There was no apparent advantage in the use of manganese dioxid with ammonium sulphate. No great difference was observed in the yield of straw, but the manganese dioxid alone seemed to act as a depressant.

Eight references to literature bearing on the subject are appended.

**How to remedy the scarcity of fertilizers**, E. MIÈGE (*Comment Remédier à la Pénurie des Engrais*. Paris: J. B. Baillière & Sons, 1916, pp. 59).—This pamphlet discusses the scarcity of fertilizing materials due to the European war, and describes methods of utilizing fertilizing materials from natural sources, especially green manuring; conserving crop residues; rotation of crops, including legumes; proper cultivation; and the use of relatively cheap soil amendments.

**Buying and using fertilizers**, R. M. SALTER (*W. Va. Col. Agr. Ext. Dept. Circ.* 87 (1916), pp. 15, figs. 7).—This circular gives information on the purchasing and use of fertilizers, with special reference to the requirements and conditions of West Virginia soils as determined by the state experiment station.

## AGRICULTURAL BOTANY.

**Rolliniopsis**, a new genus of Annonaceæ from Brazil, W. E. SAFFORD (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 8, pp. 197-204, figs. 2).—An account is given of two species of plants collected in Brazil which are considered as new forms and which, with two allied forms hitherto assigned to the genus *Rollinia*, are now assigned to a genus created for this purpose for which the name *Rolliniopsis* is proposed.

**The occurrence of bacteria in frozen soil**, E. C. HARDER (*Bot. Gaz.*, 61 (1916), No. 6, pp. 507-517, figs. 2).—During the winter of 1914-15 the author studied the effect of cold and moisture on the number of bacteria in field and

potted soils at Madison, Wis., where the variations in temperature are said to be greater than those recorded by former investigators. The results are reported to have shown a close relation between the moisture content and the number of bacteria in the soil, also a distinct retardation caused by cold, which even a higher moisture content was usually insufficient to counteract.

**Incubation studies with soil fungi, S. A. WAKSMAN and R. C. COOK** (*Soil Sci.*, 1 (1916), No. 3, pp. 275-284, fig. 1).—Describing studies with three fungi in order to ascertain the ways in which the lengths of the life cycles of fungi affect their relation to soil fertility, the author states that the optimum moisture conditions for ammonification by fungi lie near the physical optimum. While each organism has its own incubation period, the employment of a 12-day period is preferred as most suitable for practical work. The biological stage of the fungus seems to show correlation with ammonia accumulation. The largest amount appears during spore germination, the smallest during the time preparatory to actual spore formation. *Monilia sitophila* showed the largest accumulation within the first 3 or 4 days, a *Penicillium* studied between 10 and 15 days, and *Mucor plumbeus* between 6 and 10 days, these periods corresponding to those of active spore formation.

**The inoculation and incubation of soil fungi, N. KOPELOFF** (*Soil Sci.*, 1 (1916), No. 4, pp. 381-403, figs. 8).—The author, having made a study of the accumulation of ammonia by *Rhizopus nigricans*, *R. oryzae*, *Zygorrhynchus vuilleminii*, and *Penicillium* sp., states that an increase in the number of spores used to inoculate the soil caused a proportional increase in ammonia accumulation. One cc. of spore suspension is regarded as the most desirable quantity, all factors considered, for inoculations in experiments with pure cultures of soil fungi. To increase the number of inoculating spores beyond a certain point does not further accentuate the difference between ammonification of dried blood and that of cottonseed meal, the latter appearing to be a better source of food for the organisms employed.

With *Z. vuilleminii*, the maximum ammonia accumulation occurred on the twelfth day with both the above foods. *R. nigricans* gave its maximum with dried blood on the seventh, and with cottonseed meal on the ninth, day. A seven-day incubation period is regarded as the most advantageous, all factors considered, for a study of soil fungi other than those of the *Penicillium* group. After the first five days a striking increase of ammonia production is observed to occur every other day. It is thought that ammonia production depends upon the metabolic processes of the fungi rather than upon their biological stage.

**On pairs of species, R. R. GATES** (*Bot. Gaz.*, 61 (1916), No. 3, pp. 177-212, figs. 12).—The author has begun a detailed study regarding the relationships of particular species by an examination of pairs of species in the same genus taken at random. It is considered as desirable that there should be developed a taxonomy based on the anatomical and cytological study of plants.

It has been found that the several pairs of species studied bear very different relationships to each other, both as regards characters and distribution. They may occupy identical, overlapping, adjacent, or widely separated areas. One species may be a giant of another, or may differ from it by a few sharp differences which originated as units, or may show differences which can not be externally analyzed in this way. Several such pairs are discussed with the problems they present, as well as the agency of mutation (*E. S. R.*, 34, p. 629).

It is considered that crossing experiments and cytological investigations may provide the final answer to the specific questions involved.

**Studies on the correlation of morphological and physiological characters: The development of the primordial leaves in teratological bean seedlings,**

J. A. HARRIS (*Genetics*, 1 (1916), No. 2, pp. 185-196).—The author, considering a study of the relationships between slight structural variations and the physiological characteristics of individuals or of organs as one of the most fundamental lines of genetic research, has presented the results of an attempt to determine something of the more fundamental physiological characteristics to which incapacity for survival may be due. Seed of a strain of navy beans which has been under observation for several years was germinated in sand in warm houses and studied under controlled conditions as to given types of variation occurring with the greatest frequency.

The results as tabulated and discussed are considered to show that the weight of primordial leaf tissue developed by morphologically aberrant seedlings of *Phaseolus vulgaris* is, on the average, less than that produced by normal controls grown under conditions as nearly as possible comparable. Evidences obtained by employment of the conductivity and freezing point methods to detect differences in the concentration in molecules and ions in cell sap of leaves from teratological and those from normal plants suggest a lower concentration of both electrolytes and total solutes in tissue fluids of teratological plants, but the differences are slight and variable, requiring further and more refined determinations for actual demonstration of relationship. The data as a whole demonstrate merely that no clear differences in properties exist between the leaf sap of the two types of leaves.

The dependence of mutation coefficients upon external conditions, H. DE VRIES (*Ber. Deut. Bot. Gesell.*, 34 (1916), No. 1, pp. 2-7).—The author details the percentages of four clear and easily recognizable mutants obtained by growing indoors at 30° C. *Oenothera lamarckiana*, also from those obtained by crossing *O. lata* with *O. lamarckiana*, *O. lata* with *O. nanella*, and *O. lamarckiana* with *O. nanella*.

A comparison of the wood structure of *Oenothera stenomeris* and its tetraploid mutation *gigas*, W. W. TUPPER and H. H. BARTLETT (*Genetics*, 1 (1916), No. 2, pp. 177-184).—Data bearing upon the nature of the changes in particular cells and tissues which follow mutative changes in the germ plasma are presented. The authors state that the change from the 2x to the 4x chromosome number in *O. stenomeris* is accompanied by an increase of 50 per cent in the length of the vessels and of 150 per cent in the area of the cross section, an increase of 50 per cent in the length and the diameter, and of 200 per cent in the volume of the tracheids, an increase in all three dimensions of the ray cells resulting in a cell of different shape, with an increase of 274 per cent in volume, and a breaking up of the tall multiple medullary rays into their constituent simple rays.

Anthocyanin markings and cell mutation, E. KÜSTER (*Ber. Deut. Bot. Gesell.*, 33 (1915), No. 10, pp. 536, 537).—It is claimed that cell markings in many cases are to be ascribed to cell mutation, some of these, however, being independent of the formation and distribution of anthocyanin, but it is said that in a number of varieties of *Coleus hybridus* anthocyanin distribution is not to be ascribed to cell mutation.

The differentiation of starches of parent stock and hybrids, E. T. REICHERT (*Carnegie Inst. Washington Year Book*, 14 (1915), pp. 408, 409).—It is stated that the studies on the differentiation and specificity of corresponding vital substances have, during the past year, been restricted to the study of the starches of parent stocks and hybrids, noting chiefly the peculiarities observable in case of each parent and tracing them to the starch of the offspring.

The extension and improvement of methods previously employed (E. S. R., 31, p. 804) have resulted in a confirmation of the conclusions previously an-

nounced supporting the view that complex protoplasmic metabolites are specifically modified in relation to genera, species, and varieties, and hence that difference in corresponding substances constitutes a specific means of differentiation as to relationship in both plants and animals. It is stated that while the methods of investigation employed differ widely in character, the results are remarkably harmonious in the demonstration of certain principles of fundamental importance in normal and abnormal biology. Each property is claimed to be an independent physico-chemical character unit, each method and each reagent being an independent means of differentiation, so that results produced by one reagent do not indicate what will follow the employment of another. However, the property values thus determined can be reduced to figures, and when these are charted it can be seen that the sum total of these values is, in case of each starch, as distinctive of genus, species, variety, or hybrid as are ordinary botanical characters. A hybrid may be definitely referred to its true parentage, also the hybrids of separate crosses may be recognized as such. Corresponding histological examinations of plant tissue associated with macroscopical investigation have confirmed the results of the starch investigations, and strengthened the belief of the author that vital peculiarities may be resolved to a physico-chemical basis.

Notes on the anatomy of the young tuber of *Ipomœa batatas*, FLORENCE A. MCCORMICK (*Bot. Gaz.*, 61 (1916), No. 5, pp. 388-398, figs. 8).—This is an account of a study of sweet potato in line with that of Kamerling (*E. S. R.*, 33, p. 27) and of other authors named.

Biochemical and physiological study of the rest period in the tubers of *Solanum tuberosum*, C. O. APPLEMAN (*Bot. Gaz.*, 61 (1916), No. 4, pp. 265-294, figs. 2).—This work has been noted from another source (*E. S. R.*, 32, p. 129).

The vitality of seeds passed by cattle, D. MILNE (*Agr. Jour. India*, 10 (1915), No. 4, pp. 353-369).—From the experiments reported it is concluded that uncrushed wheat grains, etc., intentionally or accidentally fed to cattle working on pure culture plats during or just before seeding time are a source of serious danger to the purity of the crops.

The roots of herbaceous plants, A. P. MODESTOV (*Kornevaia Sistema Travānist'kh Rastenii*. Moscow: I. N. Kushnerev, 1915, No. 1, pp. 138, pls. 3, figs. 38).—This collection comprises four contributions. The first deals with differences in the growth attained by roots in various groups of cultivated plants, the second with the length of roots attained under conditions of natural development, and the third with the root system of flax. The fourth gives a list of related contributions, comprising over 500 titles.

Stomatal structure and function in *Camellia (Thea) japonica*, MAGDA HEILBRONN (*Ber. Deut. Bot. Gesell.*, 34 (1916), No. 1, pp. 22-31, figs. 4).—It is claimed that in *C. japonica* the walls of the guard cells are lignified and immobile except in case of very young leaves in which the stomata can still open and close. It is stated that in three species of *Thea* more or less lignified stomatal cells have now been demonstrated, namely, *T. viridis*, *T. assamica*, and *T. bohea*.

The periodicity and distribution of radial growth in trees and their relation to the development of "annual" rings, J. C. GROSSENBACHER (*Trans. Wis. Acad. Sci., Arts, and Letters*, 18 (1915), pt. 1, pp. 1-77).—Certain facts observed in a study previously noted (*E. S. R.*, 22, p. 650) have led the author to a reexamination of the extensive literature bearing upon irregularities in the time of commencement and closing of cambial activity, and a discussion is herein given of radial growth and the factors thought to determine its distribution, the author reserving for a separate paper the results obtained from a

study of the early stages of crown rot. Important hypotheses and investigations are given in some detail and compared with each other in relation to the author's observations. In the main, the present purpose of the article is to restate the questions raised by the investigators, though sometimes in modified form. A restudy of the structural and tension changes accompanying periodic growth may also, it is thought, lead to an investigation of the enzymes active during radial growth and to the effect which adverse changes of environment have upon them while in an active condition.

Winter foliation in beech, F. WEBER (*Ber. Deut. Bot. Gesell.*, 34 (1916), No. 1, pp. 7-13, fig. 1).—Potted young plants of *Fagus sylvatica*, after being exposed to acetylene gas for three days early in December and then brought into the hothouse, began to develop leaves by the end of the month, and during the first and second weeks of January the plants which had been exposed to the gas became covered with leaves while the controls showed no sign of awakening. The claim that a very prominent part is played by light in foliar development in winter is questioned. While the stimulating influence of light is admitted, it is thought that even the dim light of winter days may be more than sufficient to supply the light requirement as regards leaf development and that the winter rest of plants is therefore due primarily to other causes than a lack of illumination.

The action of light on the living organism, F. SCHANZ (*Biochem. Ztschr.*, 71 (1915), No. 4-5, pp. 406-414).—This is largely a discussion of contributions made by others than the author, who, however, claims to have shown by experimentation described that chlorophyll can act as a vigorous catalyzer even on serum albumin.

The measurement of oxidation potential and its significance in the study of oxidases, G. B. REED (*Bot. Gaz.*, 61 (1916), No. 6, pp. 523-527, figs. 2).—The author describes an apparatus and a method by which, it is claimed, excellent results may be obtained, at least in some cases, in studying the effect of a catalyzer in accelerating an oxidation reaction. Some results already obtained are to be described in subsequent papers.

The significance of color changes in oxidase reagents, G. B. REED (*Bot. Gaz.*, 61 (1916), No. 5, pp. 430-432).—Quantitative values are presented as obtained in tests intended to supply workers in oxidase reactions with quantitative as well as qualitative data upon which to proceed in their investigations of this class. The oxidation necessary to produce color in ordinary oxidase reagents or in plant chromogens appears to be very small. After the color has appeared, it is thought that the oxidation may continue without further change of color. The oxidation necessary to produce color in various reagents varies over a wide range.

A comparative study of nutritive solutions, I. V. IAKUSHKIN (JAKOUCHKINE (*Iz Rezult. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.)*, 10 (1914), pp. 258-288, figs. 6; *Niĕskol'ko Damiĕkh po Normal'n'im Smĕsĕm*, Moscow: Rĕbushinskikh, 1915, pp. 32, figs. 6).—Employing modifications as indicated of several common nutritive solutions in sand cultures, the author tested the influence exerted by each on different economic plants. These were found to respond in different ways and were modified variously by external conditions. Crone's solution, as here modified, gave improved results with millet, barley, buckwheat, and lupine. With Camelina, the solution of Prĕnishnikov was more favorable. With flax, the solutions of Knop, Hellriegel, and Prĕnishnikov gave better results than were obtained from Crone's solution.

The action of saline solutions on living plants in causing a reversible removal of basic substances from the plant, H. DEVAUX (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 15, pp. 561-563).—In experimentation described

and discussed, it is claimed that such an aquatic plant as *Elodea* can be made to give up an appreciable amount of calcium to a solution of potassium chlorid or ammonium chlorid in which it is kept for 30 minutes. This decalcifying action is accompanied with the fixation by the plant of a portion of the cations. Salts of other alkali metals can withdraw calcium, and the action is said to be reversible.

The relations between the presence of magnesium and assimilation in leaves, G. ANDRÉ (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 15, pp. 563-566).—Having followed up the work of Willstätter (E. S. R., 24, p. 329; 30, p. 311) and Mameli (E. S. R., 35, p. 435) bearing upon the alleged relation of magnesium to chlorophyll in leaves, the author found that the absolute maximum of magnesium present in the leaves was attained in horse chestnut and lilac May 4 and May 3, respectively, and in chestnut April 26. If the ratio between organic and residual magnesium be considered, these plants attained their respective maxima May 26, May 3, and June 14.

A labile form of albumin and its relation to living protoplasm, O. LOEW (*Biochem. Ztschr.*, 71 (1915), No. 4-5, pp. 306-320).—It is claimed that there is present in the cell sap, and even in the cytoplasm of many plant cells, a very labile albuminous body which is differentiated from ordinary albumin in that it may be separated by means of ammonia and organic bases from the solution, after which, as a rule, it quickly undergoes a change resulting in a stable compound. This labile and active form of albumin reacts toward coloring agents as does living protoplasm, while the protosomes coagulated by heat, acids, alcohol, or other means behave like killed protoplasm in the presence of stains. The intimate relation between the stored labile albumin and the organized labile albumin or living protoplasm is said to be shown in many ways.

The organic nutriment of green flowering plants, T. BOKORNY (*Biochem. Ztschr.*, 71 (1915), No. 4-5, pp. 321-364).—Considerable data have been obtained by the author regarding the ability of several common plants to utilize organic products, including some such as supposedly correspond to the products of decay in humus soils.

Retention of chlorophyll in yellowed and fallen autumn leaves due to attack by animal parasites, O. RICHTER (*Ztschr. Pflanzenkrankh.*, 25 (1915), No. 7, pp. 385-392, figs. 2).—Instances of retention of green color in case of certain trees by autumn leaves in spots attacked by insects, etc., are discussed. The phenomenon may be due to an interruption of the conducting vessels or possibly to the production of certain substances by animal parasites.

Abscission in *Mirabilis jalapa*, F. E. LLOYD (*Bot. Gaz.*, 61 (1916), No. 3, pp. 213-230, pl. 1, figs. 2).—The author concludes a study of *M. jalapa* with the claim that in this case abscission is not brought about by a separation resulting from the complete solution and destruction of a layer of tissue, but that the mode of abscission agrees in all essential details with that shown to occur in *Gossypium* and *Aristolochia*.

Abscission, F. E. LLOYD (*Ottawa Nat.*, 28 (1914), Nos. 3-4, pp. 41-52, figs. 3; 5-6, pp. 61-75).—A lecture delivered before the Ottawa Field Naturalists' Club, on January 27, 1914, which includes the results of observations on about 30 species of plants with special reference to the mechanism of abscission.

Daily transpiration during the normal growth period and its correlation with the weather, L. J. BIGGS and H. L. SHANTZ (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 4, pp. 155-212, pls. 2, figs. 18).—An account is given of investigations on the daily transpiration of a part of the plants included in the water requirement experiments at Akron, Colo., in 1914 and 1915 (E. S. R., 34, p. 522). The principal objects of the investigations were to determine the

march of transpiration during the growth period and the extent to which the daily transpiration is correlated with various weather factors.

During a 10-day period of maximum transpiration the daily loss of water from small grains ranged from 12 to 16 times the dry weight of the crop harvested; from millets, corn, and sorghums, 6 to 9 times; and from alfalfa, 36 to 56 times. The loss of water from the small grains during the period of maximum transpiration amounted to 1.5 kg. per square meter of plant surface per day; from Sudan grass, 0.8 kg.; and from alfalfa, 1.6 per kg. These amounts are said to be from 5 to 14 per cent of the loss during the same period from a free water surface of equal area.

In considering the march of transpiration due to changes in the plant alone, transpiration in annual crop plants is found to rise to a maximum a little beyond the middle of the growth period, after which it decreases until the plants are harvested. With perennial forage crops, such as alfalfa, there is a steady increase of transpiration to a maximum at or near the time of cutting.

Correlation coefficients are shown for the different physical factors of environment as related to the transpiration of different crops. Small grains show individually a markedly higher correlation between transpiration and the intensity of the various physical factors than was observed when all the crops were combined in one population. Corn, sorghums, millets, and legumes show a somewhat lower correlation between transpiration and the intensity of the physical factors of environment. The plants of all crops show, however, the same relative dependence of transpiration on physical factors.

**Self-warming in flowers of night-blooming *Cereus*, E. LEICK (*Ber. Deut. Bot. Gesell.*, 34 (1916), No. 1, pp. 14-22).**—Reporting results of experiments carried out in 1902 and 1904 in the botanical institute at Greifswald with *C. grandiflorus* and *C. pteranthus*, the author states that the flowers show a certain amount of self-warming, but that this does not in every case make good the loss due to transpiration and is too small to be of much biological significance. The excess temperature is related to the size of the flower and is greater when it is closed and when the humidity is high, but it shows no real periodicity and disappears at the close of the blooming period. Anthers generally develop more heat than the other floral parts.

**Measurement of evaporation rates for short time intervals, E. S. JOHNSTON and B. E. LIVINGSTON (*Plant World*, 19 (1916), No. 5, pp. 136-140, fig. 1).**—Noting the limitations of atmometers previously discussed (*E. S. R.*, 34, p. 34), the authors describe herein a form of spherical porous cup atmometers in which the intensity of evaporation, which varies from time to time, may be made to indicate its value at any given time by the height of a column of mercury affected by the fluctuations in pressure.

**A field auxanometer, G. N. COLLINS and J. H. KEMPTON (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 8, pp. 204-209, figs. 3).**—It is believed that the principal requirements for securing satisfactory measurements of the growth of plants in the open have been met by a contrivance which is described. The cost is said to be sufficiently low to permit a number of plants to be studied at the same time. The essential features are a pasteboard mailing tube, around which is secured the record sheet, mounted on an axis attached to the winding stem of an ordinary alarm clock lying on its face, and a marker adjustably attached to a glass rod suspended from a pulley and counterbalanced, its lower end being fastened to the top of the growing plant. The whole contrivance is inclosed in a box with glass front and attached adjustably to a vertical post driven near the plant to be studied. The advantages of the machine are described.

## FIELD CROPS.

The influence of atmospheric electricity on crop development, T. HEDLUND (*Ber. Verks. Alnarps Lantbr. och Mejeri Inst., 1913, pp. 67-97, fig. 1*).—Observations are reported and discussed which led to the conclusion that variations in plant development, either hereditary or otherwise, which manifest themselves in different latitudes are the result of differences in temperature and sunshine, and that there is no evidence that electric currents have any significance in this connection.

An experiment in electroculture by the Lemström system with sugar beets and grain at Alnarp is described and the data secured are shown in tables. The results were not sufficiently decisive to ascribe increases in yield to the influence of the artificially applied electric currents.

[Work with field crops on the demonstration farm at Sacaton, Arizona] (*U. S. Dept. Int., Rpt. Comr. Indian Aff., 1915, pp. 26, 27*).—Notes are given on the culture of various crops on this farm, and a yield of 890 lbs. per acre of lint of long-staple Egyptian cotton on a 4-acre plat under irrigation is reported.

Growing grain on southern Idaho dry farms, L. C. AICHER (*U. S. Dept. Agr., Farmers' Bul. 769 (1916), pp. 23, figs. 9*).—This bulletin is a discussion of the dry farming conditions of southern Idaho, based on the results obtained at the Aberdeen substation since 1911. The information given is intended in particular for those who contemplate taking up homestead claims in the Snake River basin territory. The general climatic and soil conditions are discussed. Dry farm machinery equipment is described in some detail, and recommendations are made for its use. The general cultural practices best adapted to the region are discussed, and the most productive varieties of each of the leading cereals given.

The best winter wheat varieties are those of the Crimean group of hard red winter wheats. The successful production of winter wheat is dependent upon certain climatic and topographical factors which are emphasized in the discussion. Leading spring wheat varieties are Early Baart, Pacific Bluestem, and Colorado Special. The production of this crop is also somewhat limited by conditions similar to those mentioned above. The highest-yielding oat varieties are Sixty-Day and Kherson. Winter barley has proved hardy at the lower elevations. Tennessee Winter barley has given the highest yields. Mariout and White Smyrna are the leading spring barley varieties. Winter emmer and spelt, rye, and flax have been tested at the substation, but rye is the only one of the four that can be recommended for general use. The Ivanof variety is one of the best types for this region.

Dry farm grain tests in Montana, A. ATKINSON and N. C. DONALDSON (*Montana Sta. Bul. 110 (1916), pp. 165-218, figs. 7*).—The work here reported has been noted from U. S. Department of Agriculture Bulletin 398 and Farmers' Bulletin 749 (*E. S. R., 35, p. 735; 36, p. 33*).

Measuring hay in ricks or stacks, H. B. McCLURE and W. J. SPILLMAN (*U. S. Dept. Agr., Office Sec. Circ. 67 (1916), pp. 10, figs. 4*).—This circular is a revision of material noted in Bureau of Plant Industry Circular 131 (*E. S. R., 29, p. 532*), including new data relating to errors in measurement and to the rate of settling of hay in the stack.

A table has been compiled showing the losses due to measuring 6 in. short in any dimension for the nine different shapes of stacks illustrated. The greatest error occurs in measuring width and the least in measuring the "over."

The "Department rule," as outlined, is compared with the "quartermaster's rule" and the Frye-Bruhml rule for measuring the volume of a stack in cubic

feet. The quartermaster's rule shows a variation of 25 per cent, except when used to measure medium-full, low stacks, in which case it compares favorably with the Department rule. The Frye-Bruhm rule shows a variation of 24 per cent and compares favorably with the Department rule in the measurement of the full-rounded type of stack only.

Studies of the rate of settling indicate that hay in the stack after the third day will suffer a further loss in height of approximately 17 per cent in 146 days.

Experiments with potatoes and root crops, P. R. FEDOROV (*Bezenchuk. Selsk. Khoz. Opytn. Sta., No. 70 (1915), pp. 9*).—In culture tests with potatoes the average yield for five years was largest on ground plowed from 8 to 9 in. deep, while the average for ten years was in favor of plowing to a depth of 7 in. Experiments with tubers of different sizes for seed resulted in favor of whole tubers of large or medium size and from the use of small potatoes planted two in a hill. Planting 22 in. apart each way gave the most satisfactory results. Hoeing and hilling the soil around the plants proved beneficial except in localities subject to drought.

A comparison was made of dry manure, manure ash, ordinary barnyard manure, barnyard manure and Thomas phosphate, and Thomas phosphate used alone. The use of dry manure gave the greatest yield in 1915 and also on the average for the three preceding years.

The varieties tested, given in decreasing order of yield, were Richter Imperator, Professor Maerker, Alcohol, Six-Weeks, White Elephant, Local Yellow, White Flour Ball, Local Pink, Mayflower, White Star, Delicatesse, Sunrise, Count Razumovski, Blue Giant, and Professor Wohltmann. Richter Imperator, Professor Maerker, and Alcohol produced the greatest quantity of starch.

Beet seed was sown after soaking and the plants were thinned the middle of May and the middle of June to a distance of 17 in. in the row. The Pink half-sugar beet produced the best yield. The Gerand carrot proved most productive and resistant to insect pests.

Studies in Indian oil seeds.—I, Safflower and mustard, A. and GABRIELLE L. C. HOWARD, and A. R. KHAN (*Mem. Dept. Agr. India, Bot. Ser., 7 (1915), No. 7, pp. 235-272, pls. 6, figs. 2*).—This article discusses the economic value of Indian safflower (*Carthamus tinctorius*) and Indian mustard or rai (*Brassica juncea*), describes the blossoms of these plants, presents a classification and description of types, and reports the results of observations on pollination and cross fertilization.

Observations on the blossoms of safflower under bags and nets and unprotected led to the conclusion that insects were not necessary for pollination, provided that air movement and the natural humidity were not affected. Under parchment-paper bags the average number of seeds set per head was small as compared with blossoms covered with nets and those allowed to develop in the open. A test of confining blossoms in lamp chimneys closed below and partially opened above and allowing blossoms to develop in free air to determine the effect of increased humidity on setting showed a marked inhibiting effect of the moist, confined air in the lamp chimney, but it is thought possible that temperature is a factor also and that the pollen grains do not germinate readily in moist, hot air. The effect of the season on the setting of the seed was found to be quite marked. The best results in nearly every case were secured from early planting. A study of 321 plants of four different types resulted in the determination of 52 heterozygotes, or 16.5 per cent. In connection with this indication of a high percentage of self-fertilization it is pointed out that apparently natural crossing is not essential in maintaining the vigor of the crop.

A study of the oil content of the types of Indian safflower showed a range from 13.86 to 30.19 per cent. The data showed further that there was no

antagonism between high oil content and the full development of the red coloring matter, as indicated by the faded florets.

In selection experiments with Indian mustard, 197 out of 398 single plant cultures, or 49.5 per cent, bred true. Observations on 1,067 plants of five different types showed that only 151 were heterozygotes. The results of hybridization experiments with Indian and Burma mustard showed that in four out of six cases the  $F_1$  was taller than the taller parent, while in the other two it was intermediate. When types with close and spreading pods were crossed the close arrangement prevailed in the progeny. Indian mustards with divided leaves crossed with Burma forms with entire leaves gave an intermediate  $F_1$  and a series in  $F_2$ . The  $F_1$  of a cross of late and early forms was intermediate.

**Growth of legumes as influenced by lime, A. LAPARAN Y LAYOSA** (*Philippine Agr. and Forester*, 4 (1916), No. 9-10, pp. 181-184).—The results are reported of liming experiments conducted at the College of Agriculture at Los Baños, caustic lime being applied at the rates of 1,500 and 2,500 lbs. per hectare. The use of lime proved beneficial for the production of psophocarpus, soy beans, and kulthi, but cowpeas and mongos gave better yields on the unlimed plats. The application of 1,500 lbs. per hectare gave the better results with psophocarpus and soy beans and the heavier application with kulthi. The effect of lime was more marked during rainy than dry weather.

**Abaca fiber, R. B. ESPINO** (*Philippine Agr. and Forester*, 4 (1916), No. 9-10, pp. 200-216, fig. 1, pls. 3).—The results of an anatomical study of abaca and of some cultural tests made with the crop are reported. The standard grades of abaca strips and of abaca fiber are briefly described.

In summarizing the article the author states that the erect stem of abaca contains no sclerenchyma strands near the epidermis, since it is enclosed and supported by many overlapping leaf sheaths strong enough to hold up the leaf laminae, flowers, and fruit in their proper places. The width of the sheaths of a trunk is stated to increase from the outermost to one-third or one-half of the way to the middle, and decreases from there inward. The yield of fiber varies with the width of the sheath. Fibers from the edges of the sheath were determined to be stronger per unit of weight than those from the middle part of the same sheath. The strongest fiber was obtained from the widest sheath. It is stated that the most fiber strands are situated near the outer epidermis, followed on the inside by sclerenchyma strands with some conducting tissue. Large vascular bundles are found in the internal portion of the sheath. Fiber composed of cells having thin walls and wide laminae was found weaker than fiber with cells having thicker walls and narrower laminae, and fiber composed of long cells weaker than that composed of shorter ones.

In a field test plants exposed to the sun and wind yielded almost double the amount of fiber produced by those under shade and protected from the wind. It was found that the formation of fiber was greatly influenced by cleaning the plantation.

**A study of four strains of beets, V. BOLOTOV** (*Zhur. Opytn. Agron.*, 16 (1915), No. 2, pp. 106-117).—Results of experiments are reported showing that the size of cells in beets is a hereditary character, and that beets with small cells are generally higher in sugar content than those in which the cellular structure is of larger dimensions.

**Dwarf broom corns, B. E. ROTHGEB** (*U. S. Dept. Agr., Farmers' Bul.* 768 (1916), pp. 16, figs. 7).—This gives detailed information on the production of the dwarf broom corns. The harvesting and marketing of the crop are fully discussed.

**A study of the effects of commercial fertilizers on corn, P. L. MONTELLANO** (*Philippine Agr. and Forester*, 4 (1916), No. 9-10, pp. 217-230).—The results

of a series of fertilizer experiments reported led to the conclusion that the use of reasonable amounts of double or single superphosphates is profitable on the soil in question. The crop did not appear to show any sign of preferring one form of fertilizer to another as a means of supplying the same element of plant food. Heavy applications of commercial nitrogenous fertilizers did not prove profitable. Applications of from 500 to 1,500 kg. per hectare (445 to 1,335 lbs. per acre) of lime broadcasted are considered safe and remunerative. Complete fertilizers greatly hastened the increase of height in the plants, while nitrogen alone had an invigorating effect on the development of large, deep-green leaves and heavy stalks. The use of potash seemed to affect the development of all parts of the plant.

**Maize grading, 1915, J. A. T. WALTERS** (*Rhodesia Agr. Jour.*, 13 (1916), No. 1, pp. 45-51).—The grading of maize for export in 1915 in Rhodesia is briefly reported, together with a description of the grades and the chief causes of rejection. A table shows that for a part of the year the exports consisted of 44.1 per cent of first grade and 48.7 per cent of second grade maize, while 7.2 per cent of the quantity offered was rejected.

**Cotton breeding report for 1914, B. G. C. BOLLAND** (*Agr. Jour. Egypt*, 5 (1915), No. 1-2, pp. 19-30, pls. 2).—This is a report of progress in the breeding of four varieties of cotton, presenting detailed descriptions of the characters of each variety together with tabulated statistical data based on measurements and other determinations.

**Cotton production in the United States: Crop of 1915** (*Bur. of the Census [U. S.], Cotton Prod. U. S., 1915, pp. 28*).—Statistics are presented in tables as to the cotton ginned from the crop of 1915 for the United States, the several States, and individual counties. The cotton production for the year, as reported, was 11,191,820 500-lb. bales with 880,780 500-lb. bales of linters in addition. The production of Sea Island cotton is given as 91,844 running bales.

**A study of cowpea culture with special reference to selection in the New Era variety, A. CONSTANTINO Y SAN JUAN** (*Philippine Agr. and Forester*, 4 (1916), No. 9-10, pp. 185-194).—A selection experiment with New Era cowpeas is described and the results are discussed. Of 1,000 plants studied, 13 indicated exceptional forage and 16 exceptional grain production. As compared with unselected stock the selected plants produced a gain of 251,244 kg. of seed and 1,651,483 kg. of vegetable matter per hectare (224 and 1,470 lbs. per acre).

The New Era is reported as the one variety having proved successful on the college farm and in its vicinity at Los Baños. A test of planting cowpeas on different dates showed that the best returns were secured from plantings made from August to December.

**Flax for fiber.—Its cultivation and handling, J. ADAMS** (*Canada Expt. Farms Bul.* 28, 2. ser. (1916), pp. 23, figs. 15).—A general discussion is presented on the cultivation of flax for fiber and its preparation for the market under Canadian conditions. Some of the results secured in experimental work relating to flax culture at the Canada Experimental Farms are quoted.

**Napier fodder or elephant grass (*Pennisetum purpureum*), J. A. T. WALTERS** (*Rhodesia Agr. Jour.*, 13 (1916), No. 1, pp. 87-91, pls. 4).—A description is given of this grass and its composition is compared with that of green maize. When the crop was cut March 1, 3 ft. of green growth had been made by the first week of July as compared with 2.25 ft. when cut April 1 and 6 in. when cut May 1. Two roots of the grass planted April 17, 1914, were divided into 224 individual plants on December 7. Rooted cuttings planted on a dry ridge made a good growth, although the rainfall in the first season subsequent to planting was less than 12 in.

**Methods for the determination of the hull content of oats, ZAIDE** (*Fühling's Landw. Ztg.*, 64 (1915), No. 11-12, pp. 295-311).—This article reports the results of the determination of the hull content in numerous samples of several varieties of oats, describes and discusses the different steps in the determination, and proposes methods for determining this factor as a means of ascertaining the feeding value as well as to what extent the hull content represents a variety character.

For the determination of the hull content of a sample in judging its feeding value, the author proposes the removal from an average sample of all foreign matter together with all undeveloped kernels, empty hulls, hull parts, and naked caryopses, the taking of a portion of about 25 gm. from the sample thus cleaned, the separation of the hulls and the caryopses, with the removal at this time of all kernels found to be imperfect, and the determination by weight of the perfect caryopses and their hulls calculated to a percentage basis.

For the determination of the hull content as a varietal characteristic, the sample secured as above described is divided into firsts and seconds or outer and inner kernels, and the hull content determined from each separately. It is stated that for all practical purposes it is sufficient to determine the hull content for the outer kernels only, as the hull content of the outer kernel bears a fairly constant relation to that of the inner kernel. As this procedure does not take into account the relative production of the outer and inner kernels it is suggested that if this is to be ascertained the material for study should include all the kernels produced by plants representing the average stand of the field.

**A study of the production of peanuts, G. CONSUNJI Y TONGCO** (*Philippine Agr. and Forester*, 4 (1916), No. 9-10, pp. 195-199).—Cultural notes and varietal descriptions are given, and the results of a comparison of seven varieties of peanuts are shown in tables.

The best average yields of nuts were secured from the Big Japan, Virginia Bunch, and Improved Virginia varieties. For catch crops in young plantations the American, Chinese, Big Japan, Virginia Bunch, Native Lemery, and Improved Virginia, and in old plantations the Spanish varieties; for a cover crop the Improved Virginia; for haymaking the Spanish varieties; and for marketing in the form of nuts the Chinese variety are recommended.

[**Potato experiments**], O. B. WHIPPLE (*Montana Sta. Rpt. 1915*, pp. 252, 253).—Notes are given on potato experiments conducted on the station farm and at the Judith Basin substation.

At the Judith Basin substation, Pearl, Green Mountain, and Carman No. 1 gave the highest yields. Thinning slightly reduced the yield but improved the quality of the tubers. Under dry-land conditions a planting distance of from 12.5 to 15.5 in. apart in the row gave the best results, while ridging slightly reduced the yield.

On the station farm Russet Burbank gave the highest yield among the main-crop varieties, and Early Ohio the best of the early varieties. Early thinning was found to be most effective, but only with Russet Burbank was it found to increase the yield. Pure lines of Russet Burbank and Rural New Yorker, isolated by hill selection, were tested again in 1915, but did not give noticeably higher results. The planting of cull seed for a 3-year period has only slightly increased the percentage of culls produced as compared with selected seed.

**Influence of the size of the seed tuber on the quantity and quality of the potato crop, P. IGONIN** (*Bezenchuk. Selsk. Khoz. Opytn. Sta.*, No. 67 (1915), pp. 5).—The results of the experiments here reported indicated that the starch content is higher in large than in small tubers. While the size of the seed tuber influenced the growth of the plant, the increase in tuber production was not in proportion to the size of the seed tuber. The net crop from small

tubers was greater than from large ones, but the largest crop was secured from the use of medium-sized tubers for seed. The size of the seed tuber had the same influence with early and late varieties. The yield of late potatoes was from 75 to 100 per cent greater than that of early varieties.

The cost of potato production in Russia, V. KOTELNIKOV (*Selsk. Khoz. i L'bosov.*, 249 (1915), Oct., pp. 213-243).—This article reports the cost of potato production in rubles (0.515 cts.) per dessyatine (2.7 acres) for each of the Governments of Russia. The data collected in this connection are presented in tables. The average cost of production on large and small farms in 19 Governments is given in the table below:

*Average cost per dessyatine of producing potatoes in 19 Governments of Russia.*

Kind of expenditures.	Gentlemen's estates.		Peasants' farms.	
	Rubles.	Per cent.	Rubles.	Per cent.
Labor.....	43.24	37.2	36.66	36.3
Fertilizer.....	19.26	16.6	16.62	16.4
Seed.....	35.25	30.4	32.83	32.3
Incidentals.....	6.61	5.7	3.25	3.2
Land lease.....	11.77	10.1	11.77	11.7

Green-manuring rice, G. C. SHERRARD (*Agr. Jour. Bihar and Orissa [India]*, 3 (1915), No. 1, pp. 66-68).—The results of green-manuring rice with san hemp (*Crotalaria juncea*) and dhaincha (*Sesbania aculeata*) are reported for a series of years on three different farms.

The tabulated results show that green manuring gave an increase in the yield of rice every year at each of the places where the work was conducted. It is recommended that these green manuring crops be sown in time to reach the proper stage of development at the period when the land is ordinarily puddled, that all of the green substance of the crops be mixed with and buried in the mud, and that the rice be transplanted on the land thus prepared about a week later.

Nitrogenous fertilizers for winter rye, S. HASUND (*Tidsskr. Norske Landbr.*, 23 (1916), No. 3, pp. 139-147).—Cooperative experiments with Norwegian lime-nitrogen and Norwegian nitrate as a fertilizer for winter rye are described, and the results are reported in tables. The applications used furnished equal quantities of nitrogen. The use of Norwegian lime-nitrogen gave, in general, the same crop increase secured from the applications of Norwegian nitrate.

Factors influencing the protein content of soy beans, J. G. LIPMAN and A. W. BLAIR (*Soil Sci.*, 1 (1916), No. 2, pp. 171-178).—This is a continuation of work already noted (*E. S. R.*, 34, p. 140).

It was found that thick seeding up to 20 and 30 plants per pot increased returns as regards dry matter and total nitrogen, the latter fact seeming to indicate increased or intensified utilization of atmospheric nitrogen by means of symbiotic bacteria in case of the thicker plantings. It seems certain that by thick seeding of soy beans, much more nitrogen is secured from a given area, much of which is drawn from the atmosphere.

In order to test whether, with abundant available nitrogen in the soil, legumes draw less nitrogen from the air than when soil nitrogen is scanty, experiments were carried out with gradually increasing nitrogenous fertilizers. From these experiments, in which both tops and roots gave the same sort of results, it is concluded that in the sand cultures at least, nodule formation is not decreased by applications of nitrogenous fertilizers. The plants evidently used some of the applied nitrogen, but the excellent growth made by the checks would lead

to the belief that perhaps 65 to 75 per cent of the nitrogen recovered was secured from the atmosphere.

Variety tests with pot cultures and in the open field are also described and discussed.

Variations in the sugar content of the beet in relation to selection in Italy, O. MUNERATI, G. MEZZADROLI, and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 9, pp. 605-637, figs. 2).—For the purpose of this study analyses of beets planted April 2, May 19, and July 11 were made on different dates from July 23 to January 5. Also different portions of the root were analyzed to determine the distribution of sugar in the beet. The data secured relating to sugar content and its fluctuation and the weight of the leaves and the roots are given in tabular form.

The results of the analysis of different portions of individual beets showed the least variation in the samples taken from the upper third of the root. From other data obtained it is concluded that the composition of the beet at a certain time can not be regarded as indicating its sugar content on an earlier or a later date, if left to grow. It was further brought out that two beets apparently identical in all respects may present different values in the transmission of their sugar-producing qualities and that, on the other hand, beets differing in weight and in sugar content may have the same merits or defects.

The influence of defoliating sugar beets on their sugar content, O. MUNERATI, G. MEZZADROLI, and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 10-11, pp. 743-771, figs. 2).—The experiments described were conducted to determine the influence of removing the leaves of sugar beets on their sugar content, and for this purpose analyses of normal and defoliated beets were made on different dates of the growing period. The results of the analyses are given in tables.

It was found that beets allowed to develop normally after transplanting increased constantly in weight in proportion to the development of the new leaves. The beets with abundant foliage were able to treble their weight in about three months, while beets with scanty foliage increased but little in weight. Beets from which the leaves were removed from time to time did not increase in weight, and in many instances showed a loss. In the normal beets the total sugar content was also closely related to the development of the leaves, while the beets defoliated sustained a loss in sugar content. The percentage of sugar also diminished constantly and progressively in the defoliated beets, while in the normal beets, with the exception of an initial reduction due to the growth of the first leaves, the percentage of sugar remained nearly stationary during the constant and progressive increase in the weight of the root. In certain individuals not only was the weight of the root greatly increased and in consequence the total sugar, but also the percentage of sugar. It was found that the defoliated beets were reduced in storage quality. The authors believe that their results confirm the claim that the production of new leaves is carried on at the expense of the sugar contained in the root.

Notes on the growth of sugar cane, J. M. TALUQDAB (*Agr. Jour. Bihar and Orissa [India]*, 3 (1915), No. 1, pp. 15-28, pl. 1).—Observations are reported on the rate of growth of sugar cane, and the results of excessive growth measurements are given in tabular and graphical form.

Variation in the rate of growth noted during the season suggested that if certain canes spend more energy for their growth during a certain period they will have less energy at their disposal during the period of time immediately following, which causes a reduction in the rate of development. It is concluded from the data obtained that the rate of growth depends upon the degree of moisture and temperature of the soil and the atmosphere, that these two factors

must cooperate in their action, and that the effect of both is influenced and controlled by the individuality of the type of cane and its accumulated energy.

**Chemical changes during the ripening of sugar cane,** J. MIRASOL Y JISON (*Philippine Agr. and Forester*, 4 (1915), No. 5-6, pp. 101-108).—A study of the chemical changes occurring in ripening sugar cane is reported, and the results of experiments with local Philippine varieties are presented. The analytical data are given in tables.

It was determined that during the ripening period a point is reached when the purity is very high, the sucrose content at its maximum, and the reducing sugar at its minimum, and that sugar made from the juice at this stage is of high grade. It was observed that after this point is reached and maintained for a length of time depending on the variety, the soil, and climatic conditions, the purity and sucrose content of the cane decrease and the reducing sugar increases. The upper third of the cane was found to contain the least sucrose and the most reducing sugar, together with a low degree of purity. It is stated that the sugar produced from a given area of Los Baños White cane by a modern mill is of more than twice the value of sugar obtained from the same area by native processes.

**A comparison of annual cropping, biennial cropping, and green manures on the yield of wheat,** B. A. MADSON (*California Sta. Bul.* 270 (1916), pp. 3-14, fig. 1).—This bulletin is an amplification of the results obtained from cereal investigations reported in Bulletin 211 (E. S. R., 24, p. 637). A study is made of the effect of continuous cropping, alternate cropping, and fallow and green manuring on the yield of wheat and on the soil.

Continuous cropping rapidly decreased the yield of wheat to a point below profitable production. Fallow was found to be the most effective means of maintaining the productiveness of semiarid soils, although the use of green manure crops increased the yield above that of continuous cropping. A decided difference was noted in the effect of different cover crops upon wheat production, the outstanding feature being that a cereal should not be used as a green manure in a cereal rotation.

The organic matter added to the soil from a green-manure crop seems to be lost through oxidation the following summer, and the humus content of the soil, or the humus nitrogen content, does not appear to be increased. The favorable effects of green-manure crops must therefore be attributed to other causes than the increase of humus in the soil. Frequent fallowing will probably deplete the humus content of the soil, although it greatly stimulates production.

**The irrigation of wheat,** F. S. HARRIS (*Utah Sta. Bul.* 146 (1916), pp. 3-32, figs. 22).—This bulletin gives the results of irrigation experiments with wheat extending over a period of four years. The general literature on the subject is reviewed, together with 17 bulletins published by the Utah Station dealing with the irrigation of wheat. The experiments were divided into two groups: (1) The plats to which varying quantities of water were added weekly, and (2) the plats receiving a uniform amount of water at each of four fixed stages in the growth of the crop. These stages were (1) when five leaves had developed, (2) when the plants were just preparing to head out, (3) when most of the plants were in bloom, and (4) the dough stage. Some of the more striking results are as follows:

The highest yields were obtained with three irrigations of 5 in. each applied at the first, second, and third stages of growth. Irrigation water applied after the grain was planted but before it was up and that applied after the dough stage decreased the yield. If only one irrigation is to be given it should be applied at the first stage of growth. The date of maturity of wheat was retarded by excessive irrigation. Economy in water was increased by the use

of barnyard manure. From 75 to 95 per cent of the yield of irrigated wheat under the various systems of irrigation was produced by the natural precipitation.

The detailed results of the experiments are given in tabular form.

**Yellow-berry in wheat: Its cause as indicated by its composition,** W. P. HEADDEN (*Proc. Soc. Prom. Agr. Sci.*, 36 (1915), pp. 41-56).—This paper reviews the conclusions of a number of investigators of this subject, and presents the results of experiments by the author in support of the contention (E. S. R., 33, p. 41) that the ratio of available nitrogen to available potassium, and not the climatic conditions, is the principal factor in determining flintiness and starchiness of wheat.

An experiment on wheat is noted in which 12 in. of water was applied in addition to a rainfall of 9.94 in. from spring to harvest in comparison with growing wheat with a rainfall of 8.37 in. during the same period. Under these two methods of culture both flinty and yellow-berry wheat was produced. The differences in composition of flinty and starchy kernels grown in this experiment on the same plat were found to be identical with those of the flinty and starchy kernels of the same wheats grown under the same conditions but receiving either nitrogen or potassium. It is stated that wheat grown on contiguous plats of the same land and from the same lot of seed produced dark or flinty kernels with the application of nitrates, and light-colored, starchy kernels with the application of potassium. It was further shown that the application of nitrogen suppressed the phosphorus while the application of potassium did not increase it. The samples of yellow-berry wheat analyzed in this connection contained approximately 50 per cent more phosphorus than the flinty samples.

Another experiment was made to determine the effects of applying 1, 2, and 3 acre-feet of water. Marquis wheat sown April 2 received its first and last irrigations May 11 and August 15, respectively. The plats receiving 3 acre-feet of water were irrigated at intervals of from 8 to 12 days, while the plats receiving 2 acre-feet were given five irrigations and those receiving 1 acre-foot three irrigations. The wheat produced from all these plats was badly affected by yellow-berry, but the analytical results indicated no such differences as were found between the flinty and yellow-berry wheats. A sample grown with 1 acre-foot of water contained 10.423 per cent crude protein, 7.669 per cent true gluten, and 0.45 per cent phosphorus; that grown with 2 acre-feet, 10.557 per cent crude protein, 7.381 per cent true gluten, and 0.449 per cent phosphorus; and that receiving 3 acre-feet, 10.519 per cent crude protein, 8.079 per cent true gluten, and 0.454 per cent phosphorus. A sample of wheat grown with an application of 1 acre-foot of water on another soil contained less than 15 per cent of yellow-berry and had a protein content of 15.998 per cent, of true gluten 11.042 per cent, and of phosphorus 0.374 per cent.

Three trials were made to show that well-rotted manure does not produce the results shown to follow the application of nitrogen in the form of sodic nitrate. The manure was applied at the rate of approximately 16 loads per acre and the water used was 1, 2, and 3 acre-feet. In the wheat produced on these plats yellow-berry was just as prevalent as in the grain grown without manure. The crude protein in three samples grown without manure was 10.423, 10.557, and 10.519 per cent, and in three samples grown with manure 10.813, 10.519, and 11.931 per cent. The true gluten in the grain grown without manure was 7.669, 7.381, and 8.079 per cent; with manure, 7.864, 8.005, and 7.904 per cent; while the phosphorus in the grain grown without manure was 0.45, 0.449, and 0.454 per cent, and with manure, 0.452, 0.456, and 0.458 per cent.

**Witch weed or rooi-bloem (*Striga lutea*):** A new pest of the maize crop in Rhodesia, J. A. T. WALTERS (*Rhodesia Agr. Jour.*, 13 (1916), No. 2, pp. 234-236).—This article discusses briefly the relation of this plant to maize culture and suggests a method of control. The witch weed is parasitic on the roots of the maize plant, which remains short and stunted and even fails to produce an ear when attacked. "It is computed that a single plant frequently produces a thousand seeds, and it is known that these seeds retain their germinating power for years."

**Contributions to the control of weeds by means of chemical substances, especially sulphuric acid,** W. GELPKE (*Beiträge zur Unkrautbekämpfung durch chemische Mittel, insbesondere durch Schwefelsäure. Diss. Univ. Giessen, 1914, pp. 74, pls. 6*).—Results of experiments in weed control by means of the following substances are described: Ferrous sulphate, iron chlorid, sulphuric acid, sodium chlorid, sodium carbonate, borax, chrome alum, potassium bichromate, manganese dioxide, acid potassium sulphate, carbolineum, carbolic acid, potash soap, calcium cyanamid, nitrate of soda, sulphate of ammonia, kainit, Thomas slag, and cupro-azotin.

For the destruction of wild mustard a 15 to 20 per cent solution of ferrous sulphate was found adequate. Other weeds, exclusive of the grasses, were destroyed by the use of sulphuric acid in solutions ranging from 3 to 10 per cent of acid of 66° Baumé. The relatively weaker solutions applied at the rate of from 1,000 to 1,500 liters per hectare (107 to 160 gal. per acre) are recommended, and applications of this kind are reported as causing no serious injury to growing grain. The use of this solution was most effective at the time the weed plants had from three to five leaves. It was found that the use of sulphuric acid solution did not destroy the underground parts of those weeds naturally provided with well-developed root systems, especially when the plants were in an advanced stage of growth.

A list of 71 references to literature on the subject is given.

## HORTICULTURE.

**Diseases and pests of garden plants,** M. VAN DEN BROEK and P. J. SCHENK (*Ziekten en Beschadigingen der Tuinbouwgewassen. Groninger: J. B. Wolters, 1915, vols. 1, pp. XII+382, figs. 157; 2, pp. VIII+252, figs. 70*).—Part 1 of this work contains descriptive accounts of the destructive insects, birds, animals, and other pests of plants, as well as the more important fungus diseases. Part 2 describes the various means of combating pests and diseases of garden plants. A résumé of the principal laws enacted in various countries relating to pests and diseases of plants is included.

**Muck crops,** A. E. WILKINSON (*New York: Orange Judd Co., 1916, pp. XIII+257, figs. 82*).—A treatise on vegetable growing on muck land. The first few chapters discuss the nature, distribution, and value of muck and methods of reclaiming muck land. The succeeding chapters treat in detail of the culture of different vegetables, information being given relative to specific requirements, varieties, preparation of the soil, planting, care of crops, fertilizer, harvesting, marketing, yield, costs, and returns. The subject matter is drawn primarily from the experience of practical men.

[Report of horticultural investigations], O. B. WHIPPLE (*Montana Sta. Rpt. 1915, pp. 250-252*).—In continuation of previous work (*E. S. R.*, 33, p. 534) mulching experiments were conducted with something over 20 different vegetables. The mulch, which consisted of 5 or 6 in. of straw, proved to have a retarding influence on practically all crops, the warm season crops suffering the most. While the mulch conserved more moisture than cultivation, it lowered the

soil temperature so much as to offset the increased moisture conservation. Cauliflower was the only crop which showed any improvement, the yield and quality of heads being considerably better on mulched plats. Plants on mulched plats suffered much more from the frosts of late spring and early fall. The work is to be continued in other sections of the State where conditions are hotter and drier than at the station.

The work on premature seeding of celery was continued. Seedlings started February 2 and set in the field June 17 produced 64 per cent of seed stalks, while seedlings started March 2 and set in the field June 17 produced only 15 per cent. Soil made very rich with well-rotted manure increased the percentage of seed stalks in the case of early planting about 20, as compared with plants in good average greenhouse soil. Moving the plants of the early planting to cold frames early, where their growth was checked by cool temperatures, increased the amount of seed stalks by 30 per cent. A severe trimming of the tops at transplanting time also had a tendency to increase the number of seed stalks.

Variety tests with cabbage, cauliflower, and onions are briefly noted.

At the horticultural substation in the Bitter Root Valley apple trees in plats which have been in clover two years out of each three-year period since the orchard was planted have not only made the best growth, but have produced the most fruit. During the eight years of growth the trees on clean cultivated plats have not only produced less fruit and less growth, but are now in very bad condition due to lack of soil fertility. Most of the varieties of apples suffering the previous year from blight were again seriously affected. The Wealthy variety has shown the greatest susceptibility at the crown of the tree and just below the surface of the ground. It would appear that this variety must be worked on some resistant stock if it is to be planted commercially. Vanderpool Red gives promise of becoming a good commercial variety for such altitudes as that of the Bitter Root Valley. Of the sour cherries under test, Dyehouse and Baldwin appear to be the best early ones and Morello and Wragg the best late ones.

Tests conducted at the Judith Basin substation have demonstrated that even in the nonirrigated sections of Montana a good collection of ornamental trees and shrubs can be grown.

Notes on the newer varieties, P. THAYER (*Ohio State Hort. Soc. Ann. Rpt.*, 49 (1916), pp. 45-49).—This comprises notes on the newer varieties of orchard and small fruits under observation at the Ohio Experiment Station.

Do we need new varieties of commercial fruits? E. J. WICKSON (*Trans. and Proc. Cal. Assoc. Nurserymen*, 5 (1915), pp. 43-50).—In this paper the author calls attention to some weaknesses of present varieties of commercial fruits and suggests qualities which should be sought for in producing new varieties.

Five years' experiments in orchard fertilization, F. H. BALLOU (*Ohio State Hort. Soc. Ann. Rpt.*, 49 (1916), pp. 94-103).—An abridged report of investigations previously noted (*E. S. R.*, 36, p. 40).

Pruning investigations, V. R. GARDNER, J. R. MAGNESS, and A. F. YEAGER (*Oregon Sta. Bul.* 139 (1916), pp. 92, figs. 99).—This bulletin reports the following pruning studies conducted at the station:

*The early summer pruning of young apple trees*, V. R. Gardner (pp. 3-45).—Preliminary experiments started by C. I. Lewis and E. J. Kraus of the station in 1910 showed that early summer pruning of young apple trees aided in the development of the framework of the trees and stimulated fruit spur formation. The present investigation was started in 1912 to find out to what extent this is the case and how the earlier bearing condition is brought about. Some of the trees in the experimental orchard received no pruning, some were pruned in the ordinary way late in the dormant season, and others were similarly

pruned during the dormant season and also given a heavy early summer (July 1 to 10) thinning out and heading back. Records of growth under the varying pruning treatments included number and length of shoots, shoot diameter, trunk circumference, and number and distribution of fruit spurs.

The results of this investigation as a whole are summarized as follows:

"The data relating to shoot growth indicate that on the average the unpruned tree increases in size a little more rapidly than the tree that is winter pruned only, or that is both winter and summer pruned. Its average annual shoot growth is less, but it loses none of this by pruning, and hence its net increase is greater. Broadly speaking, there is but little difference in increase in size between trees that are winter pruned only and those that are both winter and summer pruned. The summer-pruned trees lose more shoot growth from pruning, but they produce nearly enough more to compensate for the additional loss.

"The amount of shoot growth produced any one season by young apple trees that have not yet developed many spurs is closely correlated with the amount they made the preceding season and shows little correlation with the amount of (i. e., the severity of) their winter pruning. Likewise the amount of shoot growth produced late in the summer, following early summer pruning, is closely correlated with the amount of the shoot growth possessed by the tree at the time of summer pruning and shows little correlation with the amount of (i. e., the severity of) the summer pruning.

"During certain portions of the growing season the winter-pruned trees of certain varieties increase in trunk circumference more rapidly than trees that have been both summer and winter pruned; during other portions of the year the reverse is the case. There seems to be a close correlation between increase in trunk circumference at any period during the summer and the leaf area possessed by the tree at that particular time.

"In some varieties heavy early summer pruning has the effect of causing those shoots remaining after the pruning to thicken and become more stocky than those in trees that are not summer pruned. In other varieties the shoots in the trees that are winter pruned only are the thicker and stockier. In all the varieties studied the late shoot growth on the summer-pruned trees (i. e., the shoot growth formed after the summer pruning) is comparatively slender.

"Summer pruning of the type described affords a direct stimulus to fruit-spur formation. Some of the buds on the basal portions of the shoots that are left after the summer pruning almost invariably grow out into fruit spurs during the latter part of the summer. Those that remain dormant during the latter part of the summer are just as apt to develop into spurs the following year as similarly situated buds on shoots that are not summer pruned.

"The late summer-shoot growth of the summer-pruned trees is very productive of fruit spurs the season following its formation. A high percentage of its buds develop into spurs. Herein, apparently, lies the chief gain in fruit-spur production from the summer pruning. On the trees that are winter pruned only, there is no growth to correspond with it. There is little or no relation between the severity of the summer pruning and the number of spurs to each unit of shoot length that remains.

"Summer pruning of the type described affords a means of developing a fruit-spur system in young apple trees earlier than is possible with the ordinary method of winter pruning only; it is estimated that its judicious use with varieties bearing mainly upon spurs will enable the apple grower to bring his trees into bearing approximately a year earlier than is otherwise possible, and still maintain and develop a good framework.

"Summer-pruned trees show a tendency to mature their wood a little later in the fall and might consequently be expected to be more susceptible to winter injury. They have not, however, proved more susceptible to bark splitting caused by severe winter weather."

*The influence of summer pruning on bud development in the apple*, J. R. Magness (pp. 46-77).—The investigation upon which the present paper is based was conducted to determine some of the influences of certain types of summer pruning on buds of the apple. It included a study of the effect of these types of pruning upon developing flower buds on spurs, upon leaf buds borne on spurs, and upon axillary buds on the current season's growth, whether leaf or fruit. The trees included in the work were in their fourth season of growth when the first summer pruning was given them. But studies were conducted on seven representative varieties of apples, the buds being collected at different intervals during the year, prepared, stained, and mounted for further comparison. The investigation as a whole is summarized as follows:

"The method and season of spur fruit bud differentiation and development was found to be identical with that described by previous investigators. Spur leaf buds developed during early summer, but little growth occurred later than buds developed during early summer, but little growth occurred later than July in those varieties investigated.

"Axillary buds developed very rapidly for a time following their initial formation, then grew slowly until about the time shoot growth ceased. Initial differentiation of axillary fruit buds occurred about one month later than in spur buds on the same trees. The main differentiation took place during late August and September. Method of development of axillary fruit buds seemed to be exactly like that of spur fruit buds. However, they followed spur buds in point of time of differentiation, and never entirely caught up with them. The difference between axillary buds in general and buds on spurs in general seemed to be in degree of development rather than in method. No influence of the early summer heading backs could be detected in the number of fruit buds formed on established spurs. Early summer heading back tended greatly to reduce the number of fruit buds formed on the one year wood. Leaf buds on pruned shoots, both on the primary and secondary growth, were not visibly influenced by the pruning. They appeared to function like similarly located buds on unpruned shoots. This, coupled with the fact that the form of the summer-pruned shoot allows many axillary buds to be left at the time of the following winter pruning, accounts for the greatly increased number of spurs in trees that have received regularly an early summer heading back."

A bibliography of cited literature is appended and the study is illustrated by a number of microphotographic plates.

*A statistical study of the fruit-spur system of certain apple trees*, A. F. Yeager (pp. 78-92).—This investigation was conducted to determine what relation various characteristics of the spur bear to fruit production. Two series of data were collected. One entire series was furnished by a single 25-year-old Grimes tree. The second series was obtained for the purpose of learning something about the life histories of old spurs, and the spurs were obtained from Grimes, Domine, and Yellow Bellflower trees, all approximately 25 years old. The results secured from the data as a whole are summarized as follows:

"As a general rule, the percentage of spurs which flowered decreased more or less rapidly with age, depending on the variety. The percentage of spurs bearing fruits decreased much more rapidly than the percentage blooming. On the average, spurs decreased in amount of fruit to each bearing spur as they became older, though the more vigorous of the older spurs produced more than

the average of the younger spurs. Among spurs of uniform age, there was a marked degree of correlation between their length and production. This correlation was more pronounced as the spurs became older.

"There was considerable correlation between the amount of growth that a spur made one year and its production the following year. The average Grimes spur grew more during the year that it produced fruit, than the year it was not fruiting. Spurs bearing two years in succession averaged somewhat less to each spur the second season than other spurs that bore no crop the first season.

"There was a high degree of correlation between the diameter of spurs and their production. This was practically the same for old spurs as for young. Spurs of the same age borne on branches of large diameter bore a larger amount of fruit than those on smaller branches.

"In the Grimes tree studied the largest average production for each spur was found in the south quarter. The upper part of the tree produced more to each spur than the lower, and there was a slightly greater production for each spur on the outside of the tree than on the inside. Wherever the average production for each spur was less than the mean, the average age was more."

**Factors which influence regular bearing in an apple orchard, J. H. GOURLEY** (*Ohio State Hort. Soc. Ann. Rpt., 49 (1916), pp. 67-73*).—The substance of this paper, which is based on the results of experiments at the New Hampshire Experiment Station, has been noted from another source (*E. S. R., 34, p. 833*).

**Arsenate of lime in combination with soluble sulphur as a spray material for the apple, G. E. SANDERS** (*Agr. Gaz. Canada, 3 (1916), No. 4, pp. 305-307*).—In view of the severe burning of apple leaves caused by soluble sulphur in combination with lead arsenate when used as a summer spray, tests were made of a mixture of arsenate of lime and soluble sulphur with special reference to its burning effect. Data are given showing the results of these tests, together with comparative tests of other combinations of soluble sulphur, Bordeaux, and lime-sulphur.

Briefly stated, the experiments show that a mixture of arsenate of lime, 0.75 lb. to 40 gal., and soluble sulphur, 1 lb. to 40 gal., caused practically no burning on apple foliage. It is pointed out that soluble sulphur should not be exposed to the air for any length of time, since the sodium sulphid crystals change to sodium thiosulphate or photographers' "hypo" which, even though it is more or less readily soluble in water, is incapable of any further change and therefore of no value as an insecticide or a fungicide.

**Apple storage problems, L. GREENE** (*Trans. Ind. Hort. Soc. 1915, pp. 72-96, figs. 6*).—This paper comprises a popular summary of the author's storage investigations previously noted (*E. S. R., 30, p. 41*).

**False blossom of the cultivated cranberry, C. L. SHEAR** (*U. S. Dept. Agr. Bul. 444 (1916), pp. 7, pls. 4, figs. 2*).—A popular descriptive account, with illustrations, of the false blossom of cranberries which the author in his investigations of cranberries in cooperation with L. R. Jones found to be a physiological trouble due to unfavorable cultural conditions (*E. S. R., 31, p. 841*). To overcome the disease it is recommended that optimum conditions for growth should be provided, including good drainage, clean culture, and pruning. Where diseased vines are numerous the bog should be scalped and replanted with healthy vines. To prevent the further spread of the disease only vines known to be absolutely free from it should be planted.

**The cranberry industry and its possibilities in Canada, M. B. DAVIS** (*Canada Expt. Farms Bul. 29, 2. ser. (1916), pp. 30, figs. 20*).—This bulletin contains practical directions for cranberry culture, the subject matter being based

upon the experience of successful cranberry growers in Nova Scotia and Massachusetts.

**Southern strawberries**, G. M. DARROW (*Jour. Heredity*, 7 (1916), No. 12, pp. 531-540, figs. 6).—The author describes the work of prominent strawberry breeders in the South, and shows the important bearing it has had in developing the strawberry industry of the South.

**Graft stocks resistant to drought**, L. MALLET (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 37 (1916), No. 46, pp. 470-473).—The results are given of a test conducted on the plains of Herault, France, in which a large number of different stocks on which were grafted the Aramon variety of grape were compared with reference to their resistance to dry conditions.

**Citrus observations in Brazil**, A. D. SHAMEL (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 11, pp. 396-408, fig. 1).—A descriptive account of the agricultural expedition of the U. S. Department of Agriculture to southern Brazil in 1913-14 in quest of information relative to the navel orange and other citrus and agricultural crops of that country.

**Severinia buxifolia**, a citrus relative native to southern China, W. T. SWINGLE (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 19, pp. 651-657, figs. 2).—The species here described is a shrub readily propagated from cuttings and suitable for hedges. Experiments have shown that *S. buxifolia* can withstand unusually large amounts of salt in the soil. Hence, it is suggested that it may prove of interest as a stock for citrus fruits in regions having alkali in the soil or having salty irrigation water.

**Variation in the flowers of the papaya**, L. B. KULKARNI (*Poona Agr. Col. Mag.*, 7 (1915), No. 2, pp. 102-112, pls. 4).—This paper has been previously noted as a reprint (E. S. R., 35, p. 449).

**Notes on the history, uses, and cultivation of the papaya**, H. J. DAVIES (*Dept. Land Rec. and Agr. United Prov. Agra and Oudh, Bul.* 37 (1916), pp. 7).—A popular bulletin prepared with special reference to conditions in India.

**Excelsa coffee**, P. J. S. CRAMER (*Teysmannia*, 27 (1916), No. 4-5, pp. 211-223, pls. 2).—The author gives an account of the present status of Excelsa coffee as grown in Java since its introduction from Africa in 1905.

**Preliminary investigations of value in the selection of the tea plant**, C. P. C. STUART (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee*, No. 40 (1916), pp. XII+328, pls. 27, figs. 21).—This work has been prepared with special reference to its use in the conduct of scientific and practical selection experiments with tea plants. It contains a historical and botanical study of the tea plant, methods of conducting investigations with populations and races of tea, a study of the tea blossom and tea seed, and an outline of methods for conducting selection work. A bibliography of cited literature is appended.

**Report on certain aspects of the tea industry of Java and Sumatra**, G. D. HOPE (*Indian Tea Assoc. [Pamphlet]*, 2 (1916), pp. 122, pls. 11).—This comprises the results of a survey of the tea industry of Java and Sumatra, special attention being given to methods of work on estates that are considered to be improvements on those now employed in India.

**Notes on new plants and plants not well known**, W. HUNT (*Ann. Rpt. Hort. Socs. Ontario*, 10 (1915), pp. 57-64, figs. 2).—A brief review of some of the newer or less known ornamental plants that have been tested in the borders and grounds of the Ontario Agricultural College during the past five years.

**Notes on novelties and plants not well known**, F. E. BUCK (*Ann. Rpt. Hort. Socs. Ontario*, 10 (1915), pp. 85-87).—Descriptive notes are given on a number of the newer annual flowers being tested at the Central Farm, Ottawa.

The roses, COCHET-COCHET and S. MOTTET (*Les Rosiers. Paris: O. Doin & Sons, 1916, 4. ed., rev. and enl., pp. XIV+370, figs. 66*).—A revised and slightly enlarged edition of this work (E. S. R., 22, p. 449).

## FORESTRY.

The book of forestry, F. F. MOON (*New York and London: D. Appleton & Co., 1916, pp. XVII+315, figs. 79*).—A popular treatise on forestry prepared with special reference to its use by the general reader, and particularly "Young America."

Part 1 tells the story of the forest, how it grows, how it is planted, the life of a forester, etc., the subject matter being based on methods and conditions as found in the United States. Part 2 contains popular descriptions of the more important trees and shrubs in each section of the country, including also a key for the identification of the woods of the different species. Appended to the work are tables showing the uses of the principal American species, volume table measurements for white pine, a list of reference books on forestry, and definitions of terms used in forestry and logging.

The mountain communities and the Forest Service, C. DUBOIS (*Univ. Cal. Jour. Agr., 4 (1916), No. 3, pp. 71-74, figs. 3*).—In this article the author describes some extension phases of the U. S. Forest Service employees' work among mountain communities.

Grazing resources of the National Forests, J. T. JARDINE (*Univ. Cal. Jour. Agr., 4 (1916), No. 3, pp. 79-81, figs. 3*).—An account of the extent and utilization of the grazing facilities of the National Forests.

A new method of germinating acorns for forest planting, J. W. HARSHBERGER (*Amer. Forestry, 22 (1916), No. 275, pp. 687, 688, fig. 1*).—The method here described and illustrated consists in taking immature acorns, the embryos of which have not ceased to grow, and planting them. The result is the elongation and growth of the embryo into a young seedling plant without any intervening rest period.

In view of the trouble in successfully preserving the viability of acorns over winter, it is suggested that the acorns can be planted while green in protected frames and carried over winter in the frame or cool greenhouse already germinated and ready to plant out in the spring.

Studies in tolerance of New England forest trees.—III, Discontinuous light in forests, G. P. BURNS (*Vermont Sta. Bul. 193 (1916), pp. 3-23, pls. 4*).—In continuation of previous studies of tolerance of forest trees (E. S. R., 31, p. 338), the author reviews the literature dealing with light measurements in forests and presents the results of light readings secured from a number of tree zones in Michigan and Vermont. The readings were made with special reference to determining the value of light measurements in the forest and their significance in a study of the light requirements of our forest trees. A bibliography of cited literature is appended.

Summing up the results of previous investigators relative to light quality, the author concludes that filtered light in the forest has little value as a means of decomposition of carbon dioxide; the important light in the forest is weakened white light. Data secured from readings in Michigan and Vermont forests show conclusively that the present methods of determining light values in the open forest are of little value inasmuch as the so-called shade of the forests is a discontinuous shade and a constantly changing factor. "The variations in light intensity due to clouds, the impossibility of making equal exposures in repeated readings, the variability of the forest cover thus requiring the operator to choose a typical station for the forest under consideration, and the habit of

reading only on bright days about noon; all these make for inaccuracy and emphasize the difficulty, if not impossibility, of determining the relation of forest trees to light by a study in the forests."

Since results of forest measurements indicated that the relation of tree growth to light as an influencing factor can be determined only by controlled greenhouses and nursery trials, the author constructed a series of frames, some of which were covered with white cheesecloth and others with similar cloth dyed black. With such an equipment it was found that a continuous shade of any desired percentage of total light can be obtained within certain limits during an entire experimental period. A preliminary experiment with white pine, balsam fir, and hemlock seedlings was conducted under such shade. It was found that when the light intensity was so far reduced as to register 0.0266 no starch whatever could be detected in the white pine leaves. Hemlock reached its minimum at about 0.005. The trials are being continued, using several more varieties. Observations made of white pine seedlings growing under large cheesecloth shade with the light reduced to varying degrees of intensity indicate that the chief factor of the slow development in some cases was not lack of light but some other factor, possibly root competition for water and food in the soil.

The author is of the opinion that "tolerance" should be stricken from the vocabulary of forestry students unless it can be made to mean more than light relationship, since it expresses not a light relationship but the total relationship of a tree to all factors of the habitat.

**The Keene forest.**—A preliminary report, J. W. TOUMNEY and R. C. HAWLEY (*Yale Forest School Bul. 4 (1916), pp. 25, pls. 4*).—This comprises a descriptive account of the Keene forest of the Yale School of Forestry, located near Keene, N. H., including suggestions relative to work accomplished and to a general policy for the treatment of each type of wood in the forest.

**Forests of Porto Rico; past, present, and future, and their physical and economic environment,** L. S. MURPHY (*U. S. Dept. Agr. Bul. 354 (1916), pp. 99, pls. 13, figs. 7*).—This bulletin comprises a report of a survey of forest problems in Porto Rico conducted by the Forest Service in cooperation with the Government of Porto Rico. It also revises and brings up to date two previous bulletins of the Forest Service dealing with the forests and forest conditions of Porto Rico (E. S. R., 11, p. 853; 16, p. 878). A general account is given of the physical and economic features of Porto Rico, together with a discussion of the condition and distribution of forests, forest formations, forest influences, commercial aspects, forest industries, products, and problems, and suggestions relative to an insular forest policy.

Appended to the bulletin is a descriptive account of Trees of Porto Rico, by W. D. Brush, L. S. Murphy, and C. D. Mell. Each species is described with reference to its nomenclature, distinguishing characteristics, wood structure, and economic uses. A bibliography of consulted literature is also appended.

**The productive capacity of the Douglas fir lands, western Oregon and Washington,** T. T. MUNGER (*Univ. Cal. Jour. Agr., 4 (1916), No. 3, pp. 92, 93, fig. 1*).—A discussion of the productive capacity of Douglas fir lands, including some data showing the current annual growth of Douglas fir forests at various ages on three separate site qualities. The discussion is based upon studies conducted under the direction of the Forest Service of the U. S. Department of Agriculture and partially noted (E. S. R., 25, p. 141).

**Hovea tapping results, Experiment Station, Peradeniya, 1915,** T. PETCH (*Dept. Agr. Ceylon Bul. 25 (1916), pp. 14*).—A progress report on tapping experiments started in 1912 (E. S. R., 33, p. 542).

**Moreh oak, a new name for Quercus morehus,** W. H. LAMB (*Jour. Wash. Acad. Sci., 6 (1916), No. 19, pp. 657, 658*).—The name Moreh oak is here pro-

posed as a standard common name for *Q. morchus*, a tree of the Sierra Nevada foothills and the north coast ranges of California.

**I, Timbers of British North Borneo. II, Minor forest products and jungle produce, F. W. FOXWORTHY** (*Govt. Brit. North Borneo Dept. Forestry Bul. 1 (1916), pp. 67+VII*).—A descriptive account of the timbers of North Borneo and their uses, including also notes on minor forest products and jungle produce.

**Trees in medicine, J. FOOTE** (*Amer. Forestry, 22 (1916), No. 275, pp. 648-653, figs. 9*).—A popular account of some medicinal uses of substances obtained from trees.

**Marketing of woodlot products, J. W. CALLAND** (*Ohio Sta. Bul. 302 (1916), pp. 41-69*).—This bulletin discusses methods of measuring woodlot products, estimating the amount of timber in the woodlot, principal products and prices, cost of lumbering, determining the stumpage value of timber, uses of the principal kinds of woods and prices, and cooperative marketing.

**Service tests of treated and untreated fence posts, H. BRADLEY** (*Bul. Amer. Ry. Engin. Assoc., 18 (1916), No. 187, pp. 39-53, figs. 4; Reprint, pp. 15, figs. 4*).—In cooperation with the Forest Service of the U. S. Department of Agriculture, experimental treated and untreated fence posts were installed during the period 1906 to 1909 at the South Carolina Agricultural Experiment Station, Clemson College, S. C.; Alabama Polytechnic Institute, Auburn, Ala.; North Louisiana Agricultural Experiment Station, Calhoun, La.; University of Minnesota, Zumbra Heights, Minn.; Iowa State College, Ames, Iowa; and Maryland Agricultural College, College Park, Md. The present report briefly describes the experiments and presents the results thus far secured.

The data show that nondurable species, especially in the South, should have at least a light top treatment in addition to the heavier butt treatment. The results as a whole clearly indicate that a good open-tank treatment of fence posts with creosote will give satisfactory results in preventing decay in most of the nondurable species. Posts treated with water-gas-tar creosote and water-gas-tar have stood up very well thus far, the creosote giving somewhat better results. Brush treatments, soaking in cold oil, and double-tank treatments where asphaltum was used as the heating media in the hot bath were not very effective in preventing decay in nondurable species. Charring was apparently of no value. Care must be taken to have the butt treatment extend well above the ground line to allow for possible changes in the ground level or for carelessness in setting. The conditions seem to be more favorable for decay when posts are set around yards, pig-sties, chicken yards, barnyards, etc., than when set in fields, meadows, or woodlots.

Butternut and willow decayed so readily in the tops that a heavy treatment of the entire post seems advisable.

Analyses of several of the creosotes used in the experiments are appended.

**Forest products of Canada, 1915.—Lumber, lath, and shingles** (*Dept. Int. Canada, Forestry Branch Bul. 58A (1916), pp. 31*).—Statistics of the production of lumber, lath, and shingles by 3,239 mills operating in Canada during the calendar year 1915 are reported.

The total value of the lumber, lath, and shingles produced in Canada in 1915 was \$69,695,477, of which lumber represented \$61,919,806.

## DISEASES OF PLANTS.

**Pathological quarantines in 1915, R. K. BEATTIE** (*Abs. in Phytopathology, 6 (1916), No. 1, p. 95*).—Quarantines for protection against the introduction of injurious plant diseases, in effect at the date of publication, exclude from the

United States all 5-leaved pines from Europe and Asia, on account of the white pine blister rust; potatoes from Newfoundland, St. Pierre, Miquelon, Great Britain, Germany, and Austria-Hungary, because of potato wart, and this quarantine is extended to include Canada and all continental Europe except Denmark and most of the Netherlands, on account of the powdery scab; sugar cane from all countries, on account of several serious diseases; all kinds of citrus plants from all foreign countries, because of citrus canker and other serious diseases; and corn from Java and India, because of *Scelerospora maydis*.

In addition several quarantines have been established to exclude insects.

Some interesting finds in the phytopathological inspection service for 1915, G. R. LYMAN (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 96).—In the inspection service in connection with the enforcement of the Federal horticultural law, there were found, during the season reported upon, citrus-canker on 19 different lots of budwood from the Philippine Islands; withertip on budwood from the Philippines, Japan, Peru, Australia, and the Fiji Islands; and powdery scab on potatoes from Peru and Ireland. The Dutch bulb disease, due to *Botrytis parasitica*, was found on two shipments of bulbs grown by the Department at Bellingham, Wash. The same disease was found on tulips from Ireland and on narcissus from Holland.

Growth of parasitic fungi in concentrated solutions, L. A. HAWKINS (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 5, pp. 255-260).—The author reports an investigation to determine the possibility of the growth of fungus parasites in solutions of a considerably higher concentration than is found in the cell sap of the host plants. Ten common parasitic fungi were grown in solutions of salts and sugars of rather high concentrations, and in experiments in which fungi were grown in solutions of potassium and calcium nitrate, sucrose, and glucose, it was found that in every case the fungi grew readily in solutions in which the diffusion tensions were much higher than the total diffusion tensions of the dissolved substances in the juices of their host plants.

Culture work on the heteroecious rusts of Colorado, E. BETHEL (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 99).—Some of the results are briefly mentioned of culture experiments which have extended over a period of five years.

*Puccinia stipæ* has been grown on 9 different genera of Compositæ, *P. andropogonis* upon 8 species representing 2 genera, and *P. agropyri* upon 4 host genera. The telial stages are reported for *Æcidium ræstelioides*, *Æ. allenii*, *Æ. phaccliæ*, *Æ. onosmodii*, and *Æ. liatridis*. Interesting or new aëcial hosts have been found for *Uromyces junci*, *Pucciniastrum pustulatum*, *Puccinia amphigena*, and some other species.

Rusts in the department of Sotshi, N. N. VORONIKHIN (VORONICHIN) (*Trudy Bûro Prikl. Bot. (Bul. Appl. Bot.)*, 8 (1915), No. 6, pp. 769-807, pls. 3, figs. 5).—The author concludes from his mycological studies during 1912 and 1913 that fungi causing rusts are widely distributed on trees and shrubs along the shores of the Black Sea and also in more elevated regions. Eleven rust-producing fungi are named, six of these being technically described as new species under the names *Antennulariella fuliginosa* (also classed as a new genus) on *Ilex aquifolium*, *Zukalia caucasica* on *Taxus baccata*, *Z. setosa* on *Prunus laurocerasus* and *Rhododendron ponticum*, *Limacinula caucasica* on *Taxus baccata*, *Chaetothyrium colchicum* on *Ilex aquifolium* and *Citrus* sp., and *Triposporium tenue* on *R. ponticum* and *Staphylea colchica*.

Two wild hosts of *Bacterium solanacearum*, H. R. FULTON and E. E. STANFORD (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 108, 109).—The authors report having isolated *B. solanacearum* from *Ambrosia artemisiæfolia* and

*Eclipta alba* and on having inoculated susceptible plants with this organism. The first host species is said to be rather resistant to the organism, while the second is quite susceptible.

Life histories of *Melanops*, C. L. SHEAR and MISS A. M. BECKWITH (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 109).—*Melanops* is reported as having been found on 13 hosts and grown in pure cultures from them. Some of the cultures produced *Dothiorella micropycnospores* and *macropycnospores*. Other cultures gave a *Sphaeropsis* of the *S. malorum* type. The taxonomic status of the organisms on the different hosts is being investigated.

Morphology and developmental conditions of *Sclerotinia trifoliorum*, V. PEGLION (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 7, pp. 521-524).—Describing a study of the forms and behavior of *S. trifoliorum*, the author states that while the fungus extended itself readily by means of mycelial fragments, he was unable to obtain in a single case germination of the sporidia. He admits that the biological significance of these bodies is still unknown.

The perfect stage of *Septoria ribis*, R. E. STONE (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 109).—As a result of three seasons' work, the author concludes that *Mycospharella grossulariæ* is the perfect stage of *S. ribis*. The only previous collection of the perfect stage of the fungus in America is said to have been that reported by Pammell from Iowa (E. S. R., 3, p. 217).

Observations on the occurrence of *Puccinia glumarum* in the United States, H. B. HUMPHREY and A. G. JOHNSON (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 96, 97).—This rust, which was first reported in the United States by Carleton in 1915 (E. S. R., 33, p. 744), is said to have been observed on *Triticum vulgare*, *T. compactum*, *T. durum*, *T. polonicum*, *T. spelta*, *Secale cereale*, *Hordeum vulgare*, *H. marinum*, *Elymus canadensis*, and *Bromus marginatus*. The most severe epidemic was observed at Moro, Oreg., where the grain was grown without irrigation and where the average rainfall is approximately 11 in. Certain varieties showed an estimated infection of from 70 to 90 per cent, and contrary to the results reported from Europe the varieties at Moro showing the severest infections gave the highest yields.

Biologic forms of *Puccinia graminis* on wild grasses and cereals, E. C. STAKMAN and F. J. PIEMEISEL (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 99, 100).—A preliminary report is given of an investigation of the biologic forms of *P. graminis*.

*P. graminis tritici* is said to infect barley, wheat, *Hordeum jubatum*, *H. spartinum*, *Elymus canadensis*, *E. virginicus*, *E. robustus*, *Agropyron occidentale*, *Bromus tectorum*, and *Hystrix patula*. Rye was attacked only weakly. Other species of *Agropyron* have been infected in the greenhouse and rust has been observed on some of them in the field, but it is not yet known whether it occurs on them commonly.

*P. graminis secalis* is found to infect rye, barley, *Hordeum jubatum*, *H. spartinum*, *E. canadensis*, *E. virginicus*, *E. robustus*, *A. repens*, *A. tenerum*, *A. occidentale*, *A. caninum*, *A. cristatum*, *A. imbricatum*, *B. tectorum*, and *Hystrix patula*.

*P. graminis avenæ* was found capable of attacking oats, *Avena fatua*, *A. elatior*, *Anthoxanthum odoratum*, *Holcus lanatus*, *Phalaris canariensis*, *Koeleria cristata*, *Dactylis glomerata*, and *B. tectorum*. It weakly infects barley, *E. canadensis*, *Lolium italicum*, *L. perenne*, and *Festuca elatior*.

Attempts to change the parasitism or increase the host range of the various biologic forms by means of bridging hosts have proved unsuccessful. The biologic forms, when isolated, have so far remained sharply fixed.

**Barberry and cereal rust in Denmark**, J. LIND (*Tidsskr. Planteavl*, 22 (1915), No. 5, pp. 767-780).—The author states that the enactment 11 years previously of the law against barberry has resulted in the gradual decrease of the cereal rust (*Puccinia graminis*) in Denmark. In 1914 it was to be found only in weakened outbreaks, occurring late in the fall, in regions where the barberry still persists.

**Puccinia on spring wheat**, N. LITVINOV (*Trudy Būro Prikl. Bot. (Bul. Appl. Bot.)*, 8 (1915), No. 6, pp. 808-815).—Observations during 1911 to 1914 on *Triticum monococcum*, *T. dicoccum*, *T. durum*, and *T. vulgare* are said to have proved the existence of races of wheat designated as showing in some cases important differences as regards resistance to *P. glumarum* and *P. triticea*.

**Further results in controlling certain barley diseases by seed treatment**, A. G. JOHNSON (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 98).—A summary is given of experiments on seed treatment of barley for control of the stripe disease (*Helminthosporium graminum*) and loose and covered smuts (*Ustilago nuda* and *U. hordei*). Various fungicides, including copper sulphate solution, copper sulphate and salt, Bordeaux mixture, formaldehyde, corrosive sublimate, and hot water, were tested.

Practically all the treatments greatly reduced and a number eliminated the loose smut, as well as the covered smut. The stripe disease was reduced by a number of the treatments, and was entirely eliminated by formaldehyde of varying strength when the seed was soaked for three, two, and one hours at temperatures of 20, 10, and 25° C. (68, 50, and 77° F.), respectively. Aside from the formaldehyde treatment, the copper sulphate and salt mixture gave the best results.

**Preliminary investigation on the deterioration of maize infected with *Diplodia zeæ***, P. A. VAN DER BIJL (BYL) (*Trans. Roy. Soc. So. Africa*, 4 (1915), pt. 3, pp. 231-239, figs. 2).—From a preliminary study of maize inoculated with *D. zeæ*, the author concludes that the diseased grain has a higher acidity than healthy grain. It is stated that infected maize gives Ori's reaction distinctly, while healthy maize gives only a slight effervescence therewith. The enzyme which causes the effervescence with hydrogen peroxid may be destroyed by a temperature of 60° C. (140° F.), causing failure of the test, although it is thought that it may be developed into one of considerable delicacy. At present, however, the acidity determinations appear to be more useful for practical purposes.

**Preliminary notes on an heretofore unreported leaf disease of rice**, G. H. GODFREY (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 97).—The author reports observing early in the fall of 1914 a peculiar leaf affection of the plants in the rice fields of Louisiana and Texas. The disease somewhat resembles ordinary black rust of cereals, and an attempt has been made to produce the fruiting bodies of the organism in cultures, but without results. On cultures in agar plates, black sclerotia-like bodies were produced which seem to develop directly upon mycelia growing out of the stromatic mass in the leaf. Inoculations with fresh cultures of these sclerotia-like bodies have produced definite lesions, but it is said that they have not yet produced the appearance of general infection which occurs on the leaf in nature. The identity of the organism and the conditions under which the infection takes place remain to be determined.

**Leaf smut of timothy**, G. A. OSNER (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 103, 104).—A leaf smut of timothy, caused by *Ustilago striæformis*, is reported as occurring abundantly in the timothy fields of New York and northern Indiana during the past two seasons. Inoculation experiments indicate that the infection takes place only during the blossoming of the plant. Seed treatment

with formaldehyde, copper sulphate solution, and hot water gave control only in the case of hot water.

A newly noted *Phyllosticta* on alfalfa in America, and its ascigerous stage, F. R. JONES (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 102, 103).—A yellow leaf blotch disease of alfalfa is reported to have been under observation for the past two years in Wisconsin, and to have been noted in Indiana, Illinois, Minnesota, South Dakota, and Iowa. The blotches are said to elongate in the direction of the veins and to become deeper in color on the older leaves. They are constantly infected with a fungus which appears to be *P. medicaginis*, and during the autumn apothecia were found which indicated that the *Phyllosticta* is the conidial stage of *Pyrenopeziza medicaginis*.

Some root diseases of the bean, W. H. BURKHOLDER (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 104).—While engaged in an investigation of a disease of the bean in western New York, the author observed a number of fungi causing more or less trouble. Among those causing serious injury were *Fusarium* sp., *Thielavia basicola*, and in a number of cases *Rhizoctonia* sp. Inoculation experiments with the *Fusarium* upon crops grown in rotation with beans gave negative results. Peas, red clover, alsike clover, and alfalfa proved susceptible to *T. basicola*. The species of *Fusarium* appears to be distinct from any that has previously been reported on the bean.

Cabbage yellows and the relation of temperature to its occurrence, J. C. GILMAN (*Ann. Missouri Bot. Gard.*, 3 (1916), No. 1, pp. 25-84, pls. 2, figs. 21).—The author concludes his report on the study of *Fusarium conglutinans*, the cause of the wilt disease called cabbage yellows, by stating that the fungus, a facultative parasite living in the soil, becomes destructive to cabbage under certain conditions, showing a somewhat high optimum temperature and a high resistance to drying both in pure culture and in the soil. Inoculation with this fungus produced the disease in a large percentage of the trials, and inoculations from diseased plants reproduced the disease, control plants remaining free from yellows. Failure of careful inoculation experiments is attributed to variations in virulence. Low temperatures (12 to 16° C. or 53.6 to 60.8° F.) prevented the development of the disease, which is favored by temperatures of 17 to 22° C.

Fourth progress report on *Fusarium*-resistant cabbage, L. R. JONES (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 102).—In continuation of reports on the production of seed of disease-resistant cabbage (E. S. R., 33, p. 346), the author describes a selection of Brunswick which, on sick soil, gave only 18 per cent of yellows as compared with 84 per cent from commercial seed. The resistant strain produced 95 per cent of heads, while the commercial controls yielded only 76.1 per cent of heads.

Relation between storm and disease, August and September, 1915, in Texas, F. H. BLODGETT (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 100, 101).—The author reports severe infections of anthracnose and bacterial spot of cotton following the storm that prevailed from August 16 to 19, 1915, in Texas. The area of greatest damage due to disease was located in the area of greatest storm activity, and was practically bounded by a line denoting 2 in. of rainfall during 24 hours of the storm.

Cucumber diseases in the Middle West, W. W. GILBERT (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 104, 105).—In connection with an investigation of cucumber diseases undertaken in cooperation with the experiment stations in Indiana, Wisconsin, and Michigan, the author reports observations on a number of these diseases which are more or less widely distributed. Among them are the cucumber mosaic disease, or white pickle; scab, due to *Cladosporium cucumerinum*; anthracnose, due to *Collectotrichum lagenarium*; wilt

disease, due to *Bacillus tracheiphilus*; angular leaf spot, a new and undescribed bacterial disease; and downy mildew, due to *Peronosplasmopara cubensis*. All of these are said to be of rather general and sometimes destructive occurrence.

**Angular leaf spot, a bacterial disease of cucumbers, E. CARLSNER** (*Abs. in Phytopathology, 6 (1916), No. 1, pp. 105, 106*).—A leaf spot disease of cucumber which has proved to be of bacterial origin is the subject of study in Wisconsin and elsewhere. The disease is characterized on the leaf by rather angular spots bounded by the larger veinlets. The spots at first have a rather water-soaked appearance, later becoming brown and often showing a ragged appearance following the breaking away of dead parts. A viscous exudate, becoming on drying a white residue, accompanies the disease, which also appears as longitudinal lesions on the stem. The disease is considered similar to that described by Burger (*E. S. R., 30, p. 648*). It is said to be destructive and widespread in Virginia, Wisconsin, and Michigan, occurring also in Illinois, Indiana, and Iowa. The causal organism has been isolated and its pathogenicity determined.

From preliminary experiments it is believed that the disease can be held in check by spraying with Bordeaux mixture.

**Steaming of soil for the control of root rot of ginseng, J. W. BRANN** (*Abs. in Phytopathology, 6 (1916), No. 1, p. 101*).—Comparative tests are claimed to show that, from the standpoints of simplicity, cost of operation, and effectiveness, steaming of soil is far superior to the formaldehyde treatment for the control of the ginseng brown root rot.

**The development of *Mycosphærella pinodes* in pure culture, R. E. VAUGHAN** (*Abs. in Phytopathology, 6 (1916), No. 1, p. 103*).—A brief description is given of the characters of *M. pinodes* observed in connection with pea blight studies carried on at the Wisconsin Experiment Station since 1911 (*E. S. R., 29, p. 645*).

**Spongospora subterranea and Phoma tuberosa on the Irish potato, I. E. MELHUS, J. ROSENBAUM, and E. S. SHULTZ** (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 5, pp. 213-254, pls. 9, fig. 1*).—The results of a study of the geographical distribution and factors governing the occurrence of *S. subterranea* are given, together with information on the relation of the fungus to its various host plants, damage to tubers, relation to soil types, moisture, etc., and control measures.

The powdery scab is known to exist in six potato-growing sections of the United States, all northern except one which is in Florida, where potatoes are grown as a winter crop. In experiments where powdery-scab-infected seed potatoes were planted in 15 localities along the Atlantic seaboard, no infections were secured, but where soil was shipped from many localities to northern Maine and planted with infected seed, 8 out of 12 lots produced a crop showing powdery scab. Periods of damp, rainy, and cloudy weather, together with poor drainage, are said to favor the development of *S. subterranea*. Besides the potato, seven other solanaceous hosts of this fungus have been determined. The absence of the canker stage of the disease in the United States is thought to be due to the short growing period afforded the potato crop in the infected districts.

A study was made of the effect of early harvesting, seed treatment, varietal response, and soil treatment as control measures for the disease, and it was found that early harvesting is beneficial in certain seasons in Maine. Seed treatment with chemicals, especially with corrosive sublimate and formaldehyde, will reduce the disease. Certain varieties of potatoes escape infection, due rather to differences in development at the time of the infection than to disease resistance, although resistance of varieties has not been fully studied.

No soil treatment was found beneficial in eradicating the disease, though sulphur at the rate of 900 lbs. per acre reduced the amount of the disease.

Several types of dry rot were found to follow attacks of *S. subterranea*. Among these, a dry rot due to a species of *Phoma* is described under the name *P. tuberosa* n. sp.

**The potato powdery scab quarantine**, R. K. BEATTIE (*Abs. in Phytopathology*, 6 (1916), No. 1, pp. 95, 96).—An account is given of the quarantine established in 1914 because of the potato powdery scab, and it is stated that a careful survey of the potato-growing States which use Maine seed showed that the disease has established itself in only one place, this being in northeastern Florida, where a slight infection is reported. Experiments by the Bureau of Plant Industry, of the U. S. Department of Agriculture, confirm the probability that this disease would not become serious outside of the northern, cooler regions. Consequently, it was considered unnecessary to continue the quarantine, which was removed September 1, 1915.

**The black leg disease of potatoes caused by *Bacillus solanisaprus***, P. A. MURPHY (*Canada Expt. Farms Bot. Circ. 11* (1916), pp. 8, figs. 6).—A brief description of the symptoms and injuries due to black leg of potato, also of the life history and control of the causal organism, *B. solanisaprus*, is given. The author suggests the careful selection of seed tubers and steeping those which are to be so used for three hours in corrosive sublimate (2 oz. to 25 gal. water) or for two hours in formalin (1 pint to 30 gal. water), with careful disinfection of knives used in cutting seed tubers and the use of well-drained soil for planting.

**Late blight and rot of potatoes caused by the fungus *Phytophthora infestans***, P. A. MURPHY (*Canada Expt. Farms Bot. Circ. 10* (1916), pp. 13, figs. 2).—Discussing briefly the symptoms, life history, and control of *P. infestans*, the cause of late blight of potato, this circular gives directions for preparing and mixing the components of Bordeaux mixture, timely use of which has been found to be effective and profitable in this connection.

**Studies in the control of storage rots of the sweet potato**, J. J. TAUBENHAUS (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 106).—In connection with investigations of sweet-potato diseases and their control (E. S. R., 34, p. 156), attention is called to the necessity for proper ventilation, fumigation, and the use of fungicides for the control of these diseases.

**Two interesting diseases on greenhouse tomatoes**, M. T. COOK and C. A. SCHWARZE (*Abs. in Phytopathology*, 6 (1916), No. 1, p. 104).—A leaf spot which is due to a fungus resembling *Ascochyta lycopersici* and a fruit rot due to *Botrytis* sp. are described as occurring on greenhouse tomatoes.

**Observations on fire blight in the Yakima Valley, Washington**, J. W. HOTSON (*Phytopathology*, 6 (1916), No. 3, pp. 288-292, pls. 2; *abs. in No. 1*, pp. 115, 116).—The author reports that in the summer of 1915 a number of unusual conditions were observed in the study of fire blight. The organism is now known to occur on cherries, to gain entrance to pear trees through leaves, to produce a red streak in the sapwood of some varieties of pears, to infect the Yakimine (a cross between a prune and a peach), and to produce an abnormal amount of fruit infection. The fruit infection in some cases was traced to injuries produced in thinning apples.

**Black rot, leaf spot, and canker of pomaceous fruits**, L. R. HESLER (*New York Cornell Sta. Bul. 379* (1916), pp. 51-148, pls. 8, figs. 20).—The results are given of an extensive study of the black rot, leaf spot, and canker of pomaceous fruits. A study was made of the host plants, varietal susceptibility, history of the disease, etc., and notes are given on its geographic distribution and economic importance. The symptoms of disease on the different parts of the

host plant are described, together with the results of a study in the morphology, physiology, and pathogenicity of the fungus. Life history studies and control measures are given. The author has tentatively adopted the name *Physalospora cydoniae* for the causal organism, thus following Arnaud (E. S. R., 27, p. 747). Attention is called to the discovery by Potebnia that the black-rot fungus is parasitized in its *Macrophoma* stage by *Helicomyces sphaeropsisidis*.

An extensive bibliography is given.

**Treatment for anthracnose** (*Vic Agr. et Rurale*, 6 (1916), No. 9, p. 155, fig. 1).—A communication from Lafforgue, at Gironde, states that anthracnose, which in years of heavy precipitation and high soil moisture attains much importance, is more advantageously treated during the winter. The treatment to be applied after a heavy frost contains 40 to 50 kg. iron sulphate, 1 liter sulphuric acid, and 100 kg. water. Another consists of 10 liters sulphuric acid in 100 liters water. After the vines are in leaf good results are obtained from the use of lime-sulphur.

**A wilt disease of the columbine**, J. J. TAUBENHAUS (*Phytopathology*, 6 (1916), No. 3, pp. 254-257, figs. 2; *abs. in No. 1*, pp. 101, 102).—A serious wilt disease of columbine is reported as occurring at the Delaware Experiment Station in 1913. A fungus which has been identified as *Sclerotinia libertiana* attacks the crown and then the stem, causing a gradual wilting and drying of the plant. The organism has been isolated and the disease reproduced artificially in the greenhouse. The sclerotia are said to be present in large numbers in the dead plants in that the fungus winters over in the usual way.

**Sclerosis of Forsythia viridissima**, V. PEGLION (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 9, pp. 655-657).—The author reports having observed since 1915 in the garden of the agricultural school at Bologna a disease of the flower stalks of *F. viridissima* which is thought to be due to the presence of *Sclerotinia libertiana*.

**A new disease of bamboo**, M. TURCONI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 7, pp. 528-532).—The author describes a serious disease observed on the branches of *Bambusa mitis* in the botanical garden of Pavia in 1914. A fungus associated therewith is regarded as a new species, the conidial form being technically described as *Melanconium bambusæ* and the ascospore stage as *Scirrhia bambusæ*.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

**A bibliography of British ornithology from the earliest times to the end of 1912**, W. H. MULLENS and H. K. SWANN (*London: Macmillan & Co., Ltd.*, 1916, pt. 1, pp. 112).—Brief biographical sketches are given of British ornithologists, followed by lists of their published works.

**Notes on Indiana earthworms**, H. V. HEIMBURGER (*Proc. Ind. Acad. Sci.*, 1914, pp. 281-285).—A list is given of 14 species observed in Indiana, with notes on their habits.

**A review of applied entomology in the British Empire**, C. G. HEWITT (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 1, pp. 1-34).—This is the annual address of the president of the Entomological Society of America, delivered at Columbus, Ohio, on December 29, 1915, in which he deals with economic entomology in the British Isles, Africa, Australia, Canada, Ceylon, Fiji, India, New Zealand, and the British West Indies.

**How gases enter insects**, W. MOORE (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 2, pp. 224-226, figs. 4).—From the experiments conducted the author concludes that gases can penetrate through other parts of the body than the spiracles.

A method of keeping alcoholic specimens, F. C. BISHOPP (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 1, pp. 94-96, fig. 1).

A new insecticide, L. SMITH (*Rpt. Agr. Expt. Sta. St. Croix, 1914-15, p. 30*).—A stock solution consisting of 4.5 lbs. whale-oil soap dissolved in 1,000 cc. of fusel oil, to which 8,000 cc. of kerosene is then added, has been found to meet the requirements of a kerosene emulsion that will keep for a long time, both in concentrated and diluted forms, without the separation of the kerosene.

Notes on some miscellaneous economic insects found in New Jersey, H. B. WEISS (*Canad. Ent.*, 48 (1916), No. 4, pp. 141-143).—Notes are given on the occurrence of several insect pests in New Jersey, including *Hemichionaspis aspidistræ*, which is a serious pest in many fern houses; *Isosoma orchidæcarum*, known as the Cattleya fly, an important pest in practically all orchid houses in the State where Cattleya species are grown, etc.

Report of the entomologist, G. N. WOLCOTT (*Rpt. Bd. Comrs. Agr. P. R.*, 4 (1915), pp. 17-22).—A brief statement of the work of the year, including summaries of Bulletins 11, 12, and 14, by T. H. Jones, previously noted (*E. S. R.*, 33, pp. 452, 453, 458).

Insect pests of the year, J. R. BOVELL (*Rpt. Dept. Agr. Barbados, 1914-15, pp. 38-43*).—This report of the occurrence and work of the year with the more important insect pests includes a revised list of the Coccidæ of Barbados, 59 in number.

Report of the economic biologist, G. E. BODKIN (*Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, App. 3, pp. 11*).—This report of the occurrence of and work with insect pests in British Guiana during the year includes lists of eight species of thrips of economic importance of which two are new to science, identified by J. D. Hood of the U. S. Department of Agriculture; and a list of Aleyrodidæ of British Guiana, identifications of several of which have been made by A. L. Quaintance, likewise of this Department. A number of hymenopterous parasites reared from various hosts of economic importance are also listed.

[Reports of] division of entomology, F. P. JEPSON (*Fiji Dept. Agr. Ann. Rpts. 1914, pp. 17-27; 1915, pp. 16-22*).—These report the occurrence of and work with the more important insects in Fiji during 1914 and 1915.

Insect and arachnid pests of 1915, R. S. MACDOUGAL (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 28 (1916), pp. 107-139, figs. 14).—This is the usual annual report of observations of the occurrence and biology of the more important insect pests of the year (*E. S. R.*, 34, p. 652).

Sarcosporidia, G. VAN DE WALL DE KOCK (*So. African Jour. Sci.*, 12 (1916), No. 6, pp. 200-212).—A summary of the present status of knowledge of these protozoan parasites.

Grasshopper control in relation to cereal and forage crops, W. R. WALTON (*U. S. Dept. Agr., Farmers' Bul. 747* (1916), pp. 18, figs. 21).—A popular summary of information relating to grasshoppers and their control.

Some northern Georgia Acridiidae, H. A. ALLARD (*Canad. Ent.*, 48 (1916), No. 8, pp. 274-279).

Notes on Orthoptera and orthopteran habitats in the vicinity of La Fayette, Indiana, H. Fox (*Proc. Ind. Acad. Sci.*, 1914, pp. 287-321).

Parthenogenesis in *Anthothrips verbasci*, A. F. SHULL (*Rpt. Mich. Acad. Sci.*, 16 (1914), pp. 46-48).—The author reports experiments which show that *A. verbasci* was reproduced parthenogenetically. It is pointed out that the discovery of parthenogenesis in this species, a form which gives more evidence of sexual reproduction in nature than almost any species in the region around Ann Arbor, greatly reduces the probability that sexual reproduction is of common occurrence in Thysanoptera as a group.

Descriptions of new Thysanoptera, J. D. HOOD (*Proc. Biol. Soc. Wash.*, 29 (1916), pp. 109-123, pl. 1).—Of the 11 species here described as new 8 are from the United States.

Feeding habits of *Sinea diadema*, H. L. PARKER (*Ent. News*, 27 (1916), No. 6, pp. 280, 281).—Through its increasing abundance in the fields in summer and its predacious habit this reduviid has become of economic importance.

The potato tingid (*Recareudus* sp.), H. L. DUTT (*Agr. Jour. Bihar and Orissa [India]*, 2 (1914), Double No., pp. 36-47).—This pest was first noticed about four years ago attacking stored potatoes in cellars at Tunia in the Champaran district. It does serious damage in the affected locality by sucking out the sap and converting the tubers into mere hard lumps which can not be used for either eating or seed purposes. Systematic, biologic, and economic data relating to it are presented.

Monograph of the North American species of *Orthotylus* (Hemiptera), E. P. VAN DUZEE (*Proc. Cal. Acad. Sci.*, 4. ser., 6 (1916), No. 5, pp. 87-128, fig. 1).—Thirty-four species of this genus of capsids recorded from North America are described, of which 24 are new.

The Anoplura and Mallophaga of North American mammals, V. L. KELLOGG and G. F. FERRIS (*Leland Stanford Jr. Univ. Pubs., Univ. Ser.*, 1915, pp. 74, pls. 8, figs. 18).—The first part of this work deals with the Anoplura. A key to the families, subfamilies, and genera is followed by descriptions of new species and determinations of old species of Anoplura, the authors having had at hand 22 species and 2 varieties, 8 species and both varieties being described as new. The second part of the work presents descriptions of new species and determinations of old species of Mallophaga, of which the authors had at hand 18 species, one of which is new. A mammalian host list of North American Anoplura and Mallophaga is included.

A catalogue and host list of the Anoplura, G. F. FERRIS (*Proc. Cal. Acad. Sci.*, 4. ser., 6 (1916), No. 6, pp. 129-213).—A synonymic catalogue of the Anoplura (pp. 135-185) is followed by a systematic host list (pp. 186-204).

Eighty-seven generations in a parthenogenetic pure line of *Aphis avenæ*, H. E. EWING (*Biol. Bul.*, 31 (1916), No. 2, pp. 53-112, figs. 19).—A detailed report of breeding investigations. The occurrence of pedogenesis is recorded, and the effect of continued parthenogenetic reproduction on virility and metabolism of a strain has been determined. The effects of temperature on growth, size, reproduction, and dimorphism are also noted.

A review of the Pterocommini, A. C. BAKER (*Canad. Ent.*, 48 (1916), No. 8, pp. 280-289).

Aphididæ found on the apple in Britain and the description of a new species from Africa, F. V. THEOBALD (*Canad. Ent.*, 48 (1916), Nos. 5, pp. 169-177; 6, pp. 202-213, figs. 5; 7, pp. 233-242; 8, pp. 261-263, fig. 1).—Eight species of plant lice have been found at different times on the apple in Great Britain, namely, *Aphis pomi*, *A. kochii*, *Siphocoryne avenæ*, *Erisoma lanigera*, *A. crataegi*, *A. runcicis*, *Phorodon humuli*, and *A. nigra* (*oxyacanthæ*), the first four of which are common. *Aphis pomonella* on the apple at Nairobi, British East Africa, is described as new to science.

A satisfactory method of rearing mealy bugs for use in parasite work, E. J. BRANIGAN (*Mo. Bul. Com. Hort. Cal.*, 5 (1916), No. 8, pp. 304-306, figs. 2).—Considerable success has been met with in the rearing of mealy bugs on potato sprouts, use having already been made of them in transporting enemies of mealy bugs from Japan to California.

A new fungus on the green scale, W. NOWELL (*Agr. News [Barbados]*, 15 (1916), No. 375, p. 302).—The green scale (*Lecanium viride* [*Coccus viridis*])

on lime twigs has been found infested by a hitherto unrecorded and as yet undescribed fungus that is related to *Empusa fresenii*.

The common cabbage worm (*Pontia rapæ*), F. H. CHITTENDEN (*U. S. Dept. Agr., Farmers' Bul. 766 (1916), pp. 14, figs. 10*).—This replaces Circular 60 of the Bureau of Entomology, previously noted (E. S. R., 17, p. 162).

The fall army worm, or "grass worm," and its control, W. R. WALTON and P. LUGINBILL (*U. S. Dept. Agr., Farmers' Bul. 752 (1916), pp. 16, figs. 13*).—A summary of information prepared with the intention of supplying the farmer and others with the necessary information concerning the life history of *Laphygma frugiperda* and its control.

The campaign against surface caterpillar at Mokameh in 1913, E. J. WOODHOUSE and H. L. DUTT (*Agr. Jour. Bihar and Orissa [India], 2 (1914), Double No., pp. 16-35, pls. 4*).—This fourth report (E. S. R., 32, p. 58) records the work of the year 1913 with *Agrotis ypsilon*.

The campaign against surface caterpillar at Mokameh in 1914-15, H. L. DUTT (*Agr. Jour. Bihar and Orissa [India], 3 (1915), No. 1, pp. 1-14, pls. 3*).—This fifth report on *Agrotis ypsilon* deals with trapping work.

On the taxonomic value of some larval characters in the Lepidoptera, C. HEINRICH (*Proc. Ent. Soc. Wash., 18 (1916), No. 3, pp. 154-164, figs. 4*).

The apple leaf-sewer, B. R. LEACH (*U. S. Dept. Agr. Bul. 435 (1916), pp. 14, pl. 1, figs. 6*).—The apple leaf-sewer (*Ancyliis nubeculana*), generally distributed over the North and Central Atlantic States, the Middle West, and in portions of Canada, when present in sufficient numbers may cause serious injury to apple foliage.

The eggs are deposited singly or in irregular groups, usually on the underside of the leaf and hatch at Winchester, Va., during June in about 8.8 days. The newly-hatched larva spends the first three or four weeks of its life under a silken covering on the underside of the leaf, the remainder of the larval feeding period of 125 to 141 days being passed within a succession of folded leaves, which it destroys by eating the upper parenchyma. It hibernates as a larva upon the ground within the fallen leaf and while in this state is able to withstand wide extremes of moisture and temperature.

"In the latitude of northern Virginia, in a normal season, pupation begins about April 20, or possibly a little before, depending on the relative lateness of the season. The larva pupates within the folded leaf upon the ground. The average pupal period of the wintering larva of the apple leaf-sewer at Winchester, Va., in 1915, was 26.05 days. In 1915 the moths continued to emerge from May 7 to June 8. They began to deposit eggs upon the apple foliage in from one to two days after emergence. Oviposition lasted from 5 to 13 days, and the moths averaged 65 eggs each. They lived from 5 to 18 days, averaging 10.3 days. The moths are active during the day, especially during the morning, at which time they appear to deposit most of their eggs.

"The principal insect enemy of the apple leaf-sewer in Virginia appears to be *Pseudomphale ancylæ* n. sp., of the family Chalcididae. At all times during the larval stage the apple leaf-sewer is very susceptible to arsenical sprays. Arsenate of lead should be used at the rate of 2 lbs. to 50 gal. of water. Bearing orchards receiving the customary spraying for the codling moth usually escape injury from the apple leaf-sewer. Young orchards should receive an arsenical spray as soon as the insect appears in numbers sufficient to cause serious damage."

A list of 13 references to the literature is appended.

Descriptions of new North American Microlepidoptera, A. BUSCK (*Proc. Ent. Soc. Wash., 18 (1916), No. 3, pp. 147-154*).

**Tertian malarial fever.—Transmission experiments with *Anopheles punctipennis*, M. B. MITZMAIN** (*Pub. Health Rpts. [U. S.], 31 (1916), No. 19, pp. 1172-1177*).—“*A. punctipennis* has been proved to be a definitive host of tertian plasmodial infection. Under the conditions cited, 32.5 per cent of the 40 mosquitoes applied were positive as against 10.5 per cent of the *A. crucians*. Only 20 specimens of *A. punctipennis* survived six days or longer after biting.

“With a blood donor of low infectivity 13 mosquitoes of *A. punctipennis* showed infection from 6 to 25 days after securing parasitized blood. Eight of the positive specimens became infective as shown by moderate to immense numbers of typical sporozoites invading the salivary glands. In a control series of 19 specimens of *A. crucians*, two were infective with the parasites of *Plasmodium vivax* 11 and 13 days after biting the blood donor.

“The infectibility of *A. punctipennis* was demonstrated in the transmission of the disease through the biting of four mosquitoes which reproduced the infection in three healthy volunteers, living in New Orleans during February, 1916, after incubation periods of 14 and 15 days. One of these persons had escaped infection four months previously from the bites of more than 200 *A. punctipennis* in two experiments with the subtertian type. From this single instance it is indicated that *A. punctipennis* served as a host of *P. vivax* but not of *P. falciparum*.”

See also a previous note (*E. S. R.*, 35, p. 361).

**The influence of various concentrations of sea water on the viability of the salt marsh mosquitoes *Aedes sollicitans* and *A. cantator*, F. E. CHIDESTER and R. PATTERSON** (*Ent. News, 27 (1916), No. 6, pp. 272-274*).—A preliminary report of experiments conducted at the New Jersey Experiment Stations. The records indicate clearly that in the field *A. sollicitans* lives and thrives in marsh water of a higher salinity than that which seems favorable to *A. cantator*.

**A mosquito collecting device, T. H. D. GRIFFITTS** (*Jour. Amer. Med. Assoc., 67 (1916), No. 2, p. 117, fig. 1*).—An apparatus combining the principles of the fly trap for use in capturing mosquitoes is described and illustrated. It is stated that of 80 specimens of *Anopheles crucians*, caught and retained in five collecting tubes and placed under lantern globes closed with mosquito netting, only one escaped in 24 hours.

**Mycetobia and the classification of the Diptera, F. KNAB** (*Ent. News, 27 (1916), No. 6, pp. 259-262, figs. 2*).

**Notes on some genera of Syrphidæ with descriptions of new species, R. C. SHANNON** (*Proc. Ent. Soc. Wash., 18 (1916), No. 2, pp. 101-113*).

**Description of two new tachinids, C. H. T. TOWNSEND** (*Ent. News, 27 (1916), No. 5, p. 217*).—*Doryphorophaga aberrans* reared from the Colorado potato beetle and from *Blepharida rhois* at Blacksburg, Va.; and *Euphorocera floridensis* reared from *Anticarsia gemmatilis* at Gainesville, Fla., are described as new to science.

**A tachinid parasite reared from an adult capsid, M. D. LEONARD** (*Ent. News, 27 (1916), No. 5, p. 236*).—The author records the rearing of *Phorantha occidentis* from *Miris dolobrata* at Ithaca, N. Y.

**Rearing of *Winthemia quadripustulata* from rhynchophorous larva, H. L. PARKER** (*Ent. News, 27 (1916), No. 5, p. 236*).—The author records the rearing of *W. quadripustulata* on January 7 from rhynchophorous larvæ taken December 5 while following a plow in a sod field near Hagerstown, Md.

**New Tachinidæ from North America, H. E. SMITH** (*Proc. Ent. Soc. Wash., 18 (1916), No. 2, pp. 94-98*).

More light on *Myiophasia*, J. M. ALDRICH (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 2, pp. 98-100, fig. 1).

Note on *Myiophasia aenea*, C. H. T. TOWNSEND (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 2, pp. 100, 101).

Observations on the habits and parasites of common flies, G. S. GRAHAM-SMITH (*Parasitology*, 8 (1916), No. 4, pp. 440-549, pls. 10, figs. 24).—In continuing investigations of flies (*E. S. R.*, 30, p. 756) the author has studied their wintering habits, seasonal distribution and abundance of species, natural enemies, etc. He concludes that among the common species of flies the very great majority of individuals pass the winter as pupæ, or more rarely as larvæ which pupate early in the spring; that a very small and unimportant minority of both sexes emerging from pupæ late in the autumn or even in the winter possibly survive as adults until spring; that the wintering habits of *Musca domestica* are still obscure; and that the "critical" point for *Calliphora erythrocephala*, *Fannia manicata*, and *F. scalaris* seems to be about 48 to 50° F., and for *Ophyra leucostoma* about 63°.

A list of 55 references to the literature is included.

The changes of the blowfly larvæ's photosensitivity with age, B. M. PATTEN (*Jour. Expt. Zool.*, 20 (1916), No. 4, pp. 585-598, figs. 12).—This is a report of experiments carried on with blowfly (*Calliphora erythrocephala*) larvæ, in which tests were made each day from hatching until pupation in order to determine what, if any, changes take place in the sign or the degree of their reaction to light. The decrease in sensitivity was found to occur coincidentally with the beginning of the migratory period.

The spike-horned leaf-miner, an enemy of grains and grasses, P. LUGINBILL and T. D. URBAHNS (*U. S. Dept. Agr. Bul.* 432 (1916), pp. 18, pls. 2, fig. 1).—This is a report of studies of *Cerodonta dorsalis*, a dipteran known since 1861 as a corn leaf miner, but which has lately been observed to work as readily in barley, millet, wheat, oats, and various grasses. It has a wide range of distribution within the United States, occurring from Indiana and Ohio in the North to southern Florida in the South, and from Massachusetts in the East to Washington, California, and New Mexico in the West, and has been collected from Porto Rico and Mexico.

The injury to plants is caused (1) by the adults puncturing the leaves on which to feed and oviposit, and (2) by the larvæ which mine in the leaves and sometimes in the stems of young, tender plants having only a limited area of leaf surface. Mines started in the leaves of such young plants are often continued down into the heart after reaching the base of the leaf to a point near or slightly below the surface of the ground. Up to the present time this species has never been recorded as a serious pest of agricultural crops. The most severely infested field observed was one of barley at Yuma, Ariz., in April, 1915, in which about 5 per cent of the plants were infested.

The eggs are deposited either on the upper or lower sides of the leaves, one in each puncture. The largest number of eggs recorded as having been deposited by a single individual was 188 and the longest period of oviposition, 33 days. Observations made at Tempe, Ariz., Columbia, S. C., and Glendale and Pasadena, Cal., have shown the period of incubation to vary from 3 to 12 days during the spring and summer months. The length of the larval stage ranges from 9 to 24 days during different seasons and in different localities. They pupate in the mines, usually in the leaf sheath. The length of the pupal stage varies from 9 to 12 days during the midsummer and from 11 to 16 days during spring and late fall in the latitude of Columbia, S. C.; from 14 to 18 days at Tempe, Ariz., during March and April; and from 12 to 24 days at Pasadena, Cal., at different seasons of the year. The adults appear to be most active when the

temperature ranges between 85 and 95° F., but when it falls below 70° they become sluggish in their movements. There are said to be at least three generations at La Fayette, Ind., from the middle of May to October 1, apparently six generations in the latitude of Columbia, S. C., and at least eight generations during the year in the vicinity of Pasadena, Cal. The average length of the life cycle is 44 days in the vicinity of Pasadena, 26.5 days from June to August at Columbia, S. C., and 37.5 days during April and May at Tempe, Ariz. Winter is passed in the pupal stage.

A large number of parasitic Hymenoptera have been reared from this leaf miner, namely, *Cirrospilus flavoviridis*, *Cyrtogaster occidentalis*, *Diaulinus websteri*, *Diaulinopsis cullichroma*, *Polycystus foersteri*, *Dacnusa* n. sp., *Chrysocharus parksi*, *Opius dimidiatus*, and *O. aridus*, which may be responsible for the almost complete disappearance of this leaf miner during mid-summer in some localities. Preventive measures mentioned include fall plowing or any thorough cultivation of grain fields to destroy the remaining stems and leaves as well as volunteer grain, and the burning of dry grasses along fence lines, etc., in late fall and early spring.

A list of 14 references to literature is appended.

**Contribution to our knowledge of American Siphonaptera**, K. JORDAN and N. C. ROTHSCHILD (*Ectoparasites*, 1 (1915), No. 1, pp. 45-60, figs. 17).—This includes descriptions of three new genera, four new species, and several new subspecies of American fleas.

On a *Nosema* (*Nosema pulicis* n. sp.) parasitic in the dog flea (*Ctenocephalus felis*), V. T. KORKE (*Indian Jour. Med. Research*, 3 (1916), No. 4, pp. 725-730, pl. 1).—In dissections made of dog fleas at the Central Research Institute at Kasauli, India, the author has found frequent infections of the digestive tract by a new species of *Nosema*, which he has named *N. pulicis*. Fleas taken from a dog, about one in every six of which were infected, were placed in a breeding cage and fed daily on wild black rats. This resulted in the spread of the parasite so that practically every other larva was infected in about three weeks' time.

**A catalogue of Philippine Coleoptera**, W. SCHULTZE (*Philippine Jour. Sci., Sect. D*, 11 (1916), Nos. 1, pp. 94; 2, pp. 95-194).—A classified catalogue of the Philippine beetles.

**A review of North American tortoise beetles**, H. S. BARBLER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 2, pp. 113-127, figs. 3).

**A new enemy of the black locust**, G. CULBERTSON (*Proc. Ind. Acad. Sci.*, 1914, pp. 185, 186; *Ann. Rpt. Ind. Bd. Forestry*, 15 (1915), pp. 166-168).—A beetle (*Chalepus dorsalis*) is reported to have worked extensively in the leaves of locust in four counties of southern Indiana during June and July, 1914.

**Biology of *Cerambyx heros***, A. BARBEY (*Bul. Soc. Vaud. Sci. Nat.*, 5 ser., 50 (1915), No. 187, pp. 621-635, figs. 8).—This longicorn beetle, widespread throughout Europe, but occurring much more frequently in the central and southern parts of the Continent, is the source of considerable injury to the oak.

**The cane-borer beetle in Hawaii and its control by natural enemies**, F. MUIR and O. H. SWEZEY (*Hawaiian Sugar Planters' Stu., Ent. Bul.* 13 (1916), pp. 102, pls. 3, figs. 31).—The first part of this work deals with the history of the search for parasites and introduction of the tachinid *Ceromasia sphenophori* from British New Guinea into Hawaii, successfully accomplished in August, 1910, an account of which by Swezey has been previously noted from another source (*E. S. R.*, 33, p. 256). Then follows an account of the life history, habits, distribution, natural enemies, etc., of the cane-borer beetle (*Rhabdocnemis obscura*), much of the data relating to which have been previously published. Artificial means of control and natural enemies in Hawaii, next taken

up, are followed by an account of the breeding and distribution of the tachinid in Hawaii.

In a discussion of the benefits derived from the introduction of the tachinid, it is shown that the reduction in the borers has resulted in a greater yield of good cane per acre, and a further increase in the yield of sugar per acre through the improvement of the quality of the juice. The number of tons of cane required to make a ton of sugar was reduced in successive years from 11.04 tons in 1911 to 9.37 tons in 1914. In many places it is now difficult to find injury by the borer where formerly much cane was injured. While the tachinids are difficult to find, it has been shown that they can locate borers even where scarce and are able to keep up their existence.

A list of 40 references to *R. obscura* is included.

Seven appendixes comprise papers by F. Muir, namely, Report on Investigations in South China (pp. 52-57), Notes on the Sugar-cane Hoppers and Borers in the Malay States and Java (pp. 58-64), Entomological Work in Borneo (pp. 65-73), and Report on the Search for the Sugar-cane Borer in the Malay Archipelago (pp. 74-79)<sup>1</sup>; Report on the Sugar-cane Borer in the Moluccas (pp. 80-87), previously noted from another source (E. S. R., 22, p. 362); Concluding Report on Travels in the Malay Archipelago in Search of Parasites for the Cane Borer (pp. 88-93), and Report on Second Trip to British New Guinea to obtain a Tachinid Fly Parasitic on the Sugar-cane Beetle Borer (pp. 94-102)<sup>2</sup>. An account by Illingworth of the introduction of *C. sphenophori* from Hawaii into Fiji has been noted (E. S. R., 32, p. 350).

Orchard bark beetles and pinhole borers, and how to control them, F. E. BROOKS (U. S. Dept. Agr., Farmers' Bul. 763 (1916), pp. 15, figs. 18).—Brief accounts are given of the fruit-tree bark beetle (*Scolytus rugulosus*), the peach-tree bark beetle (*Phloeotribus liminaris*), the apple wood-stainer (*Monarthrum mali*), and the pear-blight beetle (*Anisandrus pyri*), and the manner of combating them.

The determination of the abdominal and thoracic areas of the cerambycid larvæ as based on a study of the muscles, F. C. CRAIGHEAD (Proc. Ent. Soc. Wash., 18 (1916), No. 3, pp. 129-146, figs. 4).

Scientific queen rearing, C. W. QUINN (Science, n. ser., 43 (1916), No. 1122, pp. 939, 941).—Following a brief reference to the work by Newell previously noted (E. S. R., 33, p. 159), the author reports the results of crossing experiments with golden Italian and gray Caucasian bees.

The Isle of Wight bee disease, A. D. IMMS (Jour. Roy. Agr. Soc. England, 75 (1914), pp. 62-70, fig. 1).—A popular summary of knowledge of this disease of bees, due to *Nosema apis*, with remedial and preventive measures. A list of nine references to the literature is included.

A new bee of the genus *Dianthidium*, S. A. ROHWER (Proc. Ent. Soc. Wash., 18 (1916), No. 3, pp. 192, 193).

Notes on the biology of *Paraphelinus speciosissimus*, W. R. MCCONNELL (Ann. Ent. Soc. Amer., 9 (1916), No. 1, pp. 97-102).—This is a report of observations of *P. speciosissimus* at Hagerstown, Md., where it has been reared from Hessian fly puparia.

The species was described in 1911 from a single specimen taken on a granary window at Urbana, Ill. It has been reared by the author from puparia in wheat stubble collected at six localities in central Pennsylvania, but has not been found to occur at other points in Pennsylvania, or in Maryland, Virginia, and West Virginia. This species is a primary multiple parasite of the Hessian

<sup>1</sup> Hawaiian Sugar Planters' Sta., Ent. Circ. 1 (1907); 2 (1907); 4 (1908); 6 (1908).

<sup>2</sup> Hawaii, Planters' Rec., 1909, Nov.; 1910, Oct.

fly, from one to ten, with an average of seven, individuals having been reared from each puparium. Its complete development from oviposition to emergence was found to require from 18 to 20 days during July and August, and there appear to be three or four generations a year.

A few observations on the apple maggot parasite, *Biosteres ragoletis*, C. A. GOOD (*Canad. Ent.*, 48 (1916), No. 5, p. 168).—In these notes, supplementing data by Woods (E. S. R., 34, p. 456), the author records the occurrence of *B. ragoletis* near Digby, Nova Scotia, where it was observed to parasitize the larvæ.

One new genus and five new species of ichneumon flies, H. L. VIERECK (*Proc. Biol. Soc. Wash.*, 29 (1916), pp. 165-171).

New miscellaneous chalcidoid Hymenoptera with notes on described species, A. A. GIRAULT (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 3, pp. 291-308).—Among the species of economic importance are *Ablerus perspiciosus* n. sp., reared from the West Indian peach scale in Japan; *Habrocytus obscuripes*, reared in connection with the strawberry weevil at St. Paul, Minn.; *Uscanopsis carlylei* n. g. and n. sp., reared from an egg mass of *Membracis tectigera*, Port of Spain, British West Indies; *Oligosita oophagus* n. sp., reared from an egg mass of a leafhopper embedded in a leaf of sugar cane, Diego Martin, British West Indies; *Gonatocerus triguttatus* n. sp., reared from an egg mass of a leafhopper on orange, Caroni, British West Indies; *Aprostocetus whitmani* n. sp., reared from the eggs of *Physonota unipunctata* at St. Paul, Minn.; *Cheiloncenus albicornis*, reared from *Pulvinaria* spp. on poison ivy and from *Physokermes piceæ* at Madison, Wis.; *Ooctonus quadricarinatus* n. sp., reared in connection with bark beetles from limbs of pine infested with *Pityogenes hopkinsi*, at Syracuse, N. Y.; *Sympiesomorphelleus bicoloriceps* n. sp., reared from *Tinea* on Solanum; *Eupelminus colcoptrophagus* n. sp., reared in connection with the strawberry weevil at St. Paul, Minn.; *Hemanasoidea oculata* n. g. and n. sp., reared from *Pseudococcus citri* on bamboo at Manila, P. I.; etc.

Life history of *Habrocytus medicaginis*, a recently described parasite of the chalcis fly in alfalfa seed, T. D. URBAHNS (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 4, pp. 147-154, pl. 1, fig. 1).—This is a report of observations of *H. medicaginis*, a parasite of *Bruchophagus funebris*, commenced in the fall of 1912 and continued into 1915. Laboratory studies were conducted at Glendale and Pasadena, Cal., while field observations and collections extended over several States west of the Rocky Mountains. The parasite was first reared by the author from alfalfa seed collected at Yuma, Ariz., in August, 1912, and subsequently from collections of alfalfa seed made at points in the different alfalfa seed-growing districts between the Rocky Mountains and the Pacific coast, including California, Idaho, Utah, and Oregon. Specimens from New Mexico, Kansas, and South Dakota have also been examined.

The author's observations show that a larva of this species may completely destroy its host and become fully developed within a minimum period of five or six days after taking its first food. Under a condition of dryness, such as is brought about by hot desert winds, a resting period varying from a week to a year may follow. Development continues upon the return of warm moist conditions.

The minimum length of the larval stage as observed by the author was normally about 12 days, the maximum a year or more. The prepupal form requires two or three days, and the pupal stage varies from 10 days under favorable field conditions in midsummer to 52 days in March and April. Observations show that a period of from about 30 days to one year, and almost two years in exceptional cases, may be required for the completion of a single

generation. It hibernates in the larval stage within the infested alfalfa seeds which remain on the standing alfalfa, or on the ground when winter approaches. The undeveloped larvæ and those still in the pupal stage are usually killed by the first severe frost. In the mild climate of southern California occasional individuals of this species hibernate in the pupal stage.

The comparative rearings of *H. medicaginis* and their host (*B. funebris*) show parasitism by *H. medicaginis* in several localities to be about as follows: Corcoran, Cal., 0.8 per cent; Tulare, Cal., 2.8 per cent; Chino, Cal., 2.8 per cent; and Yuma, Ariz., 4.9 per cent.

Description of eleven new species of chalcid flies, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), Nos. 3, pp. 100-103, pl. 1; 4, pp. 113-116).—Among the species of economic importance here described as new are *Phanodiscus partifuscipennis*, reared from the hemispherical scale in California, and *Baoanusia africana*, a parasite of *Lecanium oleæ* in Cape Colony, Africa.

Descriptions of and observations on some chalcidoid Hymenoptera, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), Nos. 7, pp. 242-246; 8, pp. 265-268).—Among the species described as new are *Diaulinus intermedius* reared from *Phytomyza chrysanthemi* at Kingston, R. I.; *Psuediglyphomyia coptodiscæ* from *Coptodisca splendorerifera*, Madisonville, Ky.; *Trichogrammatomyia tortricis* n. g. and n. sp., from the eggs of *Tortrix cerasivorana*, Guelph, Ontario, in the second paper.

A new genus of pteromalid chalcidoid Hymenoptera from North America, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 7, pp. 246-248).

A new genus of lelapine chalcid flies from the United States, A. A. GIRAULT (*Canad. Ent.*, 48 (1916), No. 8, pp. 263, 264).

The pear leaf-worm, R. L. NOUGARET, W. M. DAVIDSON, and E. J. NEWCOMER (*U. S. Dept. Agr. Bul.* 438 (1916), pp. 23, pls. 2, figs. 4).—This is a report of observations and experiments with a pear sawfly (*Gymnonychus californicus*) made in California during the seasons 1911 to 1914, inclusive, and in the State of Washington during the seasons of 1914 and 1915.

The injury by this sawfly is caused almost entirely by its partial defoliation. It is quite abundant in the localities in which it occurs, and occasionally becomes a pest of serious consequence. So far as known it is a native of the Pacific coast. It is of economic importance only as an enemy of the different varieties of pears.

"There is only one generation each year. The adult or parent sawflies issue in March and April, the female sex greatly predominating. Eggs are inserted into the pear leaves, the resultant larvæ or worms feeding upon the foliage for an average period of three weeks. The larvæ may be found on the leaves during April and May, and in Washington the season is perhaps ten days or two weeks later than in California. Upon acquiring full growth the larvæ drop to the ground and bury themselves in the topmost inch of soil (a few go as deep as 3 or 4 in.) and weave around themselves a brown, oval, tough cocoon in which the insect remains for slightly over ten months, at first as larva and later for a period of two or three weeks as a pupa. At the end of the pupal stage the adult issues from the cocoon and comes forth from the ground, and thus the cycle is completed. . . .

"What few natural enemies the insect has are quite unable to control it. Artificial remedies are correlative with those used against the codling moth and also against the pear-thrips larva. . . .

"In cases of ordinary infestation the contact spray, such as is used for thrips larvæ or aphids, will prove successful in controlling the larva of the pear leaf-worm. When the infestation is severe and promises the defoliation of limbs or whole trees the poison spray should be used. The best time for appli-

cation is when the largest larvæ are about half grown and when the holes in the leaves are not larger than 0.5 in. in diameter. At this time nearly all the eggs have hatched."

Some American Hymenoptera, J. C. CRAWFORD (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 2, pp. 127, 128).

The citrus mite named and described for the first time, E. A. MCGREGOR (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 3, pp. 284-290, figs. 13).—The citrus mite, formerly considered identical with *Penthhalodes mytilaspidis*, is here described from material taken on lemon leaves at Orlando, Fla., as *Tctranychus citri* n. sp. It was introduced into California from Florida on nursery stock about 1890, and is doubtless the most injurious red spider found on citrus trees on the Pacific coast. It is severest as a pest of sweet orange in California, whereas in Florida it all but forsakes the sweet orange, and is severe only upon lemon, sour orange, and grapefruit. The citrus red spider on orange in California produces a silvering, dwarfing, and dropping of the fruit, and also causes discoloration and dropping of the foliage.

A new mite from the Hawaiian Islands, P. J. O'GARA (*Science, n. ser.*, 44 (1916), No. 1126, p. 142).—The author records observations of injury to the Chinese litchi tree (*Litchi chinensis*), growing on the grounds of the Federal Experiment Station at Honolulu, by a mite which is apparently a new species of Eriophyes.

The dispersal of leaf-blister mite of cotton, (*Agr. News [Barbados]*, 15 (1916), No. 368, p. 186).—Data are presented which indicate that the leaf-blister mite of cotton can be introduced in the seed. Observations have also shown that the full-grown mites have a tendency to ascend to the tips of leaf hairs and assume what appears to be a waiting position, the first pair of legs being extended and with which they attach to any moving object that comes in contact with them. It is suggested that leaf-blister mites would in this way attach to insects and birds and be disseminated by them.

## FOODS—HUMAN NUTRITION.

On the use of certain yeast nutriment in bread making, R. A. KOHMAN, C. HOFFMAN, T. M. GODFREY, L. H. ASHE, and A. E. BLAKE (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 781-789, figs. 3).—Experiments here reported were carried out to determine the effect of certain mineral salts, such as are commonly found in natural waters, upon the fermentative activity of the yeast and also upon the quantity of yeast necessary for leavening purposes. The mineral substances present in flour, milk, yeast, and other raw materials used in bread making were also studied. The following conclusions are drawn:

"By the use of minute quantities of ammonium and calcium salts and potassium bromate in bread, from 50 to 65 per cent of the usual amount of yeast can be saved. Incident to the economy in yeast thus effected, there is a saving of about 2 per cent of fermentable carbohydrates, calculated upon the total flour used, due to the greatly diminished consumption of these by the yeast.

"The proper use of nutrient salts for the yeast gives greater control over the dough batches and aids in the production of better and more uniform bread, regardless of the locality. The added salts conserve the inherent qualities of the dough and consequently maintain its stability and strength to a far greater degree than by the old process. The finished loaves are improved in quality, flavor, texture, bloom, and uniformity."

A cause of mustiness in bread, A. M. WRIGHT (*Jour. Soc. Chem. Indus.*, 35 (1916), No. 20, pp. 1045, 1046).—Examination for micro-organisms of flour alleged to have been the cause of mustiness, observed in bread baked from it, showed the presence of *Rhizopus nigricans* and *Aspergillus*.

Sound, palatable bread was sterilized and portions were mixed with filtered and fluid extracts of the two species of molds and incubated for 24 hours at 37° C. The samples treated with the *R. nigricans* extract developed a marked mustiness and a slight sourness in the odor and flavor, while those treated with the *Aspergillus* extract developed sourness in odor and flavor. Neither mustiness nor sourness was noted in samples of the sterilized bread incubated as a check. The conclusion was drawn that *R. nigricans* is capable of producing mustiness in bread while *Aspergillus* produced merely sourness. The changes in the bread associated with mustiness are regarded by the author as being probably brought about by the proteolytic enzyme of *R. nigricans*.

**Manufacture of [soy] bean milk at Changsha [China],** N. T. JOHNSON (*U. S. Dept. Com., Com. Rpts., No. 183 (1916), pp. 468, 469*).—The bean milk described is prepared from the small yellow [soy] bean from which the Chinese bean curd is made. The beans are soaked and crushed between stones and the crushed mass is strained, diluted in water, and boiled, after which the white milk is strained off. The milk has a specific gravity of 1.02 and a fat content of 3.125. The milk is prepared at night, bottled, and delivered fresh to the customers in the morning.

**Biochemistry of cod-liver oil,** C. FUNK (*Biochem. Bul., 4 (1915), No. 14-15, pp. 365-370*).—A preliminary report is given of experiments in which nitrogenous substances, to which are attributed the therapeutic action of cod-liver oil, were separated from the fatty constituents of the oil. Crude cod-liver oil was used, since this is richer in organic bases than the purified product.

**Physiological and pharmacological studies on coal tar colors.—I, Experiments with fat-soluble dyes,** W. SALANT and R. BENGIS (*Jour. Biol. Chem., 27 (1916), No. 2, pp. 403-427*).—This investigation was undertaken to furnish information regarding the reactions produced in the body by synthetic dyes. The questions regarding their effect on health, often raised in connection with their use in the preparation of foods, emphasizes the need of such information.

In this paper data are reported regarding the effect of the following fat-soluble dyes: Benzeneazo- $\beta$ -naphthylamin, Yellow A. B.; tolueneazo- $\beta$ -naphthylamin, Yellow O. B.; benzeneazobenzeneazo- $\beta$ -naphthol, Sudan III; benzeneazo- $\beta$ -naphthol, Sudan I; benzeneazodimethylanilin, Butter Yellow; benzeneazophenol, Oil Yellow; benzeneazoresorcinol, Sudan G.; aminoazobenzene, Spirit Yellow. These dyes were administered subcutaneously, intraperitoneally, intravenously, and by mouth to laboratory animals (rabbits and cats). The results of the investigation are summarized by the authors as follows:

“Oil-soluble and water-insoluble dyes administered to different animals were eliminated in the urine and in the bile. Elimination in the urine was usually inhibited in poisoning with zinc or oil of chenopodium. Two of the compounds of benzeneazophenol and benzeneazoresorcinol, which were isolated from the urine of rabbits, proved to be conjugated with glucuronic acid.

“Most of the dyes were deposited in the adipose tissues; staining of the nervous tissue, the kidney, and muscle was also observed in some experiments. Ten to 15 hours after intravenous injection of 25 mg. per kilo of benzeneazoresorcinol, the dye was still present in the blood.

“The toxicity of the different dyes was not pronounced even when larger doses were administered.”

**[Food and drug inspection],** E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul., 4 (1916), No. 7, pp. 163-178*).—The results are reported of the examination of several samples of foods and beverages, information is given regarding several patent medicines, and the results reported of the sanitary inspection of various establishments where foods are prepared and sold.

The food problem in wartime from the standpoint of a physician, L. DEVOTO (*Atti Soc. Ital. Prog. Sci. [Rome]*, 8 (1916), pp. 475-500).—A summary of generally accepted principles in nutrition, with special reference to the economic effects resulting from underfeeding during the present war.

The increase in the cost of food for different classes of society since the outbreak of war, FRANCES WOOD (*Jour. Roy. Statis. Soc.*, 79 (1916), No. 4, pp. 501-508).—A summary and digest of statistical data.

The food value of Great Britain's food supply, W. H. THOMPSON (*Econ. Proc. Roy. Dublin Soc.*, 2 (1916), No. 11, pp. 168-220).—This paper reports the results of a survey of the food supply. This included a collection of data regarding the total quantity of food available; a study of the quantities of protein, fat, carbohydrate, and energy which these foods would furnish; and a calculation of the quantity of food available per inhabitant. The average daily ration per person thus obtained is compared with the requirements of a number of European and American dietary standards.

A bibliography and an appendix of statistical data are included.

The German food supply and its political economy, H. SCHUMACHER (*Deutsche Volksernährung und Volksernährungspolitik im Kriege. Berlin: Carl Heymann, 1915, pp. VII+92*).—The opening sections of this pamphlet deal with the domestic food supply and possible ways of increasing it by means of reclaimed land, improved methods of agriculture, and a more careful utilization of the available fertilizers. There is a brief discussion of the food materials formerly imported and means of meeting the deficiency occasioned by the shutting off of trade.

In considering the measures taken by the Government to regulate the utilization of the available food supply, special emphasis is laid on the laws governing the consumption of breadstuffs and the economic reasons for high prices and price control. The relation of feeding stuffs to human food is also dwelt on, with particular emphasis on the utilization of potatoes.

The appendix reprints a poster addressed to German women, written by the author and used extensively in railway stations, in which the necessity for small economies is emphasized. There is also a memorandum of practical means of reducing consumption in the kitchen and of advice in choosing and storing foodstuffs, and a brief bibliography of the general subject of the pamphlet.

Studies on the growth of man, I-IV, T. B. ROBERTSON (*Amer. Jour. Physiol.*, 37 (1915), No. 1, pp. 1-42, 74-85, figs. 2; 41 (1916), No. 5, pp. 535-546, 547-554, figs. 4).—Four articles are presented.

I. *The prenatal and postnatal growth of infants* (pp. 1-42).—This article is a study of various characteristics of the growth of infants, based upon statistical data in a large maternity hospital.

II. *The postnatal loss of weight in infants and the compensatory overgrowth which succeeds it* (pp. 74-85).—In the case of a large number of South Australian infants it was found that male and female infants suffered an equal retardation of growth, which after one week was 9.2 per cent of the weight at birth. By the end of the second week 48 per cent of the loss in the case of the male and 84 per cent in the case of the female had been regained. The entire loss was made good at the end of the first month.

III. *The growth of British infants during the first year succeeding birth* (pp. 535-546).—The data reported in this paper are based on records supplied by infant welfare associations in the cities of London and Leeds. From these data a curve was constructed showing the growth of British infants during the postnatal period of 12 months, and determinations were made of variations due

to sexual and environmental differences. The characteristics of the growth curves of British infants were also compared with those of the growth curves of South Australian infants of British descent.

IV. *The variability of the weight and stature of school children and its relationship to their physical welfare* (pp. 547-554).—Data are reported regarding the variability of weight and height of school children from 7 to 14 years of age, and the influence of environment upon these variabilities.

From the seventh to the fifteenth year the rate of increase in weight of both sexes was found to increase. The variability in weight underwent a parallel increase during this period, and stature also increased at an almost uniform rate. Variability of stature was uniform and much less than variability of weight.

The author regards the measure of stature as a more reliable criterion of abnormality than the measure of weight, but states that as a sensitive indicator of the effects of environmental, physiological, or dietetic fluctuations the measure of weight is to be preferred to that of stature, provided statistical methods of investigation are employed. "Among children of 8 years of age increasing unfavorability of environment and lack of medical care resulted in a parallel increase in deficiency of weight and stature, accompanied by a decrease in the variability of weight and an increase in the variability of stature."

**The use of boiled milk in infant feeding and elsewhere**, J. BRENNEMANN (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 20, pp. 1413-1419).—In this article the author reports his clinical experience with the use of boiled milk in infant feeding, which shows, in his opinion, that boiled milk possesses several advantages over raw or pasteurized milk. Earlier work has been noted (E. S. R., 29, p. 360).

**The use of malt soup extract in infant feeding**, B. R. HOOBLER (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 20, pp. 1420-1422, figs. 2).—Methods are outlined for the use of malt soup in the infant dietary.

**The relation of diet to beri-beri**, E. B. VEDDER (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 21, pp. 1494-1497).—Experiments of the author and others are summarized, and from the data presented he formulates the following dietary rules for the prevention of deficiency diseases:

"In any institution where bread is the staple article of diet, it should be made from whole wheat flour. When rice is used in any quantity, the brown undermilled, or so-called hygienic rice, should be furnished.

"Beans, peas, or other legumes, known to prevent beri-beri, should be served at least once a week. Canned beans or peas should not be used. Some fresh vegetable or fruit should be issued at least once a week and preferably at least twice a week. Barley, a known preventive of beri-beri, should be used in all soups.

"If corn meal is the staple article of diet, it should be yellow meal or water-ground meal—that is, made from the whole grain. White potatoes and fresh meat, known preventives of beri-beri and scurvy, should be served at least once a week, and preferably once daily. The too exclusive use of canned goods must be carefully avoided."

**The influence of flesh feeding on urinary creatinin**, D. BURNS and J. E. ORR (*Biochem. Jour.*, 10 (1916), No. 3, pp. 495-503).—Data are reported regarding the amount of creatinin excreted when meat or creatin was added to an otherwise creatin-free diet. The subjects of the experiments were normal young men.

The experiments showed that the ingestion of meat caused an increased excretion of creatinin and generally the appearance of creatin in the urine,

although the amount of the increase was not proportional to the amount of meat eaten. Although cooking increased the amount of creatinin present in meat, cooked meat did not necessarily cause a greater increase in urinary creatinin than uncooked meat. Creatinin administered by the mouth was eliminated as such only to a slight extent and did not greatly change the excretion of creatinin.

**Feeding experiments with a dietary in which tyrosin is reduced to a minimum, G. TOTANI** (*Biochem. Jour.*, 10 (1916), No. 3, pp. 382-398).—Experiments were conducted with laboratory animals (rats) to obtain information regarding the necessity for tyrosin in the diet. In one experiment caseinogen, freed as completely as possible from tyrosin, was used as the basis of the diet, and in another both hydrolyzed and nonhydrolyzed gelatin were used. The results of the work are summarized as follows:

“Tyrosin could not be isolated quantitatively from the hydrolysis products of caseinogen. When the removal of tyrosin from the amino-acid mixture is made as complete as possible and is effected to an extent which certainly leaves only minimal quantities of this constituent, there appears to be no effect upon the nutritive value of the amino-acid mixture.

“In the case of the rat, the nutritive efficiency of gelatin is greatly increased by previous hydrolysis. Gelatin when fed intact appears to be badly digested and absorbed. The possibility of completely replacing the protein of a diet by hydrolyzed gelatin, plus certain amino acids, is confirmed.

“Some evidence is offered that the addition of tryptophane alone to the hydrolysis products obtained from pure gelatin made these efficient in maintaining the nutrition of animals.”

**Feeding experiments with kynurenic acid, C. ASAYAMA** (*Biochem. Jour.*, 10 (1916), No. 3, pp. 466-472, figs. 4).—Laboratory animals (rats) were given a basal diet, which supplied all of the amino acids of protein except tryptophane. To this diet tryptophane was added in one series of experiments, and kynurenic acid, a metabolic product of tryptophane, in another series. Determinations of the body weight and the general nutritive condition of the animals showed that the nutritive value of the diet was enhanced by the addition of tryptophane, but when tryptophane was absent from the food no improvement of nutrition was observed on the addition of kynurenic acid.

**The rôle of leucocytes in the work on intermediary metabolism of carbohydrates, P. A. LEVENE and G. H. MEYER** (*Ann. Inst. Pasteur*, 30 (1916), No. 4, pp. 155-159).—In the experiments here reported leucocytes, practically free from bacteria, were found to convert six carbon chain-sugars into methylglyoxal, and this in turn into lactic acid. By substituting glucose derivatives for glucose it was found that glycolytic enzymes of animal tissues had no effect on those hexoses in which one or more hydrogen atoms had been replaced by other radicals.

**The mechanism of cholesterol absorption, J. H. MUELLER** (*Jour. Biol. Chem.*, 27 (1916), No. 2, pp. 463-480).—The experiments here reported were carried out with laboratory animals (dogs). In studying the mechanism of cholesterol absorption analyses were made of the gastric and intestinal contents. After feeding cholesterol the absorption of cholesterol was followed through a thoracic duct fistula with experimental elimination of certain of the gastric juices. Experiments were carried out *in vitro* dealing with the possible action of various enzymes upon cholesterol.

The data obtained showed that bile was more closely connected with cholesterol absorption than with that of neutral fats. Experiments *in vitro* showed that “free cholesterol, in the presence of fatty acids and a suspension

of pancreas, undergoes esterification, and from control experiments it seems most likely that this is a real action by the pancreas."

Analysis of the intestinal mucosa during starvation and after feeding showed that an esterification of a large part of the absorbed cholesterol had taken place. No evidence was found that the mesenteric lymph nodes took any part in cholesterol absorption.

The cholesterol esters were found to be more resistant to the ordinary active bipases, no evidence of splitting being found, although neutral fat in the same mixture was easily saponified. In the opinion of the author the data obtained by no means explain the whole process of cholesterol absorption.

"Since no effect of the mucosa could be demonstrated *in vitro*, it is at least possible that the esterification may take place in the lumen of the intestine under the influence of the pancreatic juice, and that the esters may be absorbed as rapidly as formed."

**A study of the electrolytic method of silver cleaning, H. L. LANG and C. F. WALTON, JR. (*U. S. Dept. Agr. Bul. 449 (1916), pp. 12*).**—This bulletin reports the results of a laboratory investigation of the so-called electrolytic method of cleaning silver by bringing it in contact with a more active metal, like aluminum or zinc, while immersed in a solution of some electrolyte. Preliminary tests were made with a number of commercial devices, which showed that these are generally satisfactory. A number of factors influencing the efficiency of the method were studied, such as the effect of temperature and concentration of the cleaning solution and the relative advantages of zinc and aluminum as the active metal and of sodium carbonate and sodium bicarbonate as the electrolyte. Also, directions were formulated for the household application of this method.

Aluminum was found to be more satisfactory than zinc as the active metal, because the zinc soon becomes covered with a layer of basic zinc carbonate and hence loses its efficiency. Sodium carbonate or sodium bicarbonate, with or without the addition of sodium chlorid, was found to be equally effective as the electrolyte. It was found that the cleaning solution should be kept at the boiling temperature to secure the most satisfactory results.

The loss in weight of sterling silver and plated silver spoons cleaned 50 times by the electrolytic method was from 1.9 to 4.3 mg. This was insignificant and only about 4 per cent of the loss in cleaning with an abrasive silver polish. This is due to the fact that in the electrolytic method the tarnish of silver sulphid is reduced to metallic silver instead of being cut away by the abrasive in the older type of silver polishes.

### ANIMAL PRODUCTION.

**The respiratory exchange of animals and man, A. KROGH (*London and New York: Longmans, Green & Co., 1916, pp. VIII+173, pls. 3, figs. 31*).**—The topics treated in this monograph are the physiological significance of the exchange of oxygen and carbon dioxide; methods for measuring the respiratory exchange; the exchange of nitrogen, hydrogen, methane, ammonia, and other gases of minor importance; the standard metabolism of the organism (definition and determination); the influence of internal factors upon the standard metabolism; the influence of chemical factors upon the respiratory exchange; the influence of physical factors upon the respiratory exchange; the variations in standard metabolism during the life cycle of the individual; and the respiratory exchange in different animals. An extensive bibliography is included.

The growth and variability in the body weight of the albino rat, HELEN D. KING (*Anat. Rec.*, 9 (1915), No. 10, pp. 751-776, figs. 5).—The author finds that "when environmental conditions are uniform the growth of albino rats within a given colony tends to follow the same course and to produce individuals having a like weight at any stated age.

As a rule the male rat is heavier than the female at birth and also at all subsequent ages at which records were taken. During the first 60 days of post-natal life the body weight of the female tends to approach that of the male, but after this age the male grows more rapidly than the female and soon greatly exceeds her in body weight. At 200 days of age the male rat weighs, on the average, about 70 gm. more than the female of the same age. The female tends to increase in body weight at a much more rapid rate than does the male during the early stages of development, and she reaches her maximum weight much earlier than does the male.

"The environmental and nutritive conditions under which rats are reared have a marked influence on their body weights, as is indicated by the relation of the growth graphs constructed from data obtained from three different series of rats reared under different conditions. Variability in the body weight of the albino rat, as measured by the coefficients of variation, is greatest when the animals are about 60 days of age. It decreases slightly at 90 days, and after 120 days remains practically constant until the animals are about one year old. Very young female rats seem to show as great a range of variability in body weight as do the males, but the males are more variable than the females at all later stages of growth. The average coefficient of variation for the body weights of the 50 male rats used in this study is 13.6; that for the females is 12.1.

"In the rat there is apparently a direct correlation between the rapidity of growth and the variability in body weight after the animals have reached 60 days of age. The records collected are not in a form to give evidence regarding the correlation that exists at earlier stages of growth. Fraternal variability in the rat is less than racial variability. For the male rate the fraternal variability is about 70 per cent that of the general population; for the female it is about 55 per cent."

On the influence of exercise on the growth of organs in the albino rat, S. HATAI (*Anat. Rec.*, 9 (1915), No. 8, pp. 647-665).—The author experimented with the albino rat in order to discover the effect of long-continued exercise.

"The heart, kidneys, and liver show an average excess of about 20 per cent, while the spleen shows a similar amount of deficiency. The brain weight shows an average excess of 4 per cent, while no change is noticed in the case of the spinal cord. The ovaries give an excess of 84 per cent, while the testes give an excess of 12 per cent. The hypophysis, as well as the suprarenals, respond differently to exercise according to sex. Furthermore, these two organs show, as the result of exercise, an approach to the relations characteristic for the Norway rat. The exercised rats were either entirely free from lung infection or but slightly affected. The control rats, on the other hand, had badly infected lungs and in some series several of them were lost, presumably from the lung disease. Analysis of the data shows that the lung infection is not responsible for the changes observed in the organs."

On the composition and physiological activity of the pituitary body, I, II, F. FENGER (*Jour. Biol. Chem.*, 21 (1915), No. 2, pp. 283-288; 25 (1916), No. 3, pp. 417-422).—The first part of this investigation was conducted for the purpose of determining whether any seasonal variation exists in the pituitary

body from cattle. Such a seasonal variation would be expected to be most pronounced between glands obtained at the height of the outdoor season and those secured at the coldest period of the year, and for this reason two summer and two winter months were chosen for collection. In order to determine the difference, if any, in physiological activity between glands from various species of animals, pituitary bodies from hogs were also collected during the summer months.

It was found that the posterior lobe of the pituitary body of the hog was twice as large, in proportion to the weight of the entire gland, as that in cattle. The physiological activity of the posterior lobe, when determined according to the isolated uterus method, was practically the same for cattle (herbivora) as for hogs (omnivora). No distinct seasonal variation in activity and chemical composition of the posterior lobe of the pituitary body was found in cattle. Approximately 10 per cent of the beef glands contained colloid masses secreted between the anterior and posterior lobes. This material was insoluble in acidulated water, and did not possess any pronounced uterine-contracting power.

The material for the second study was selected from a large number of noncastrated calves from two to four months old as well as from full-grown steers. It was found that the pituitary bodies from young animals were slightly more active than the glands from full-grown cattle. This is in accordance with conditions found in other ductless glands, such as the thyroid, thymus, and suprarenals. The infant gland contained more phosphates, both in the anterior and posterior lobes, than glands from fully mature animals. The uterine-contracting active principle of the posterior lobe of the pituitary body was readily extracted from the fresh glands by water and also by neutral acidulated methyl or ethyl alcohol. The acidulated methyl-alcohol extract was more than twice as strong as the water extract, and somewhat stronger than pure crystalline  $\beta$ -imidazolylethylamin hydrochlorid.

**Commercial feeding stuffs, W. J. JONES, JR., F. D. FULLER, E. G. PROULX, C. CUTLER, and J. H. ROOP** (*Indiana Sta. Bul. 190 (1916), pp. 23-360, fig. 1*).—This bulletin gives the objects and provisions of the state feeding-stuffs law, terms adopted by the Association of Feed Control Officials, and other data relating to feeding-stuffs inspection.

Analyses are tabulated of alfalfa meal, blood meal, brewers' dried grains, distillers' dried grains, dried chicken blood, coconut meal, corn bran, corn feed meal, corn-germ meal, gluten feed, gluten meal, cottonseed meal, cottonseed feed, cold-pressed cotton seed, cottonseed hulls, dried beet pulp, fish scrap, ground bone, hominy feed, linseed meal, malt sprouts, meat meal, meat scrap, oat middlings, buckwheat hulls, buckwheat middlings, low-grade flour, red dog flour, rye middlings, tankage, wheat bran, wheat middlings, and mixed, proprietary, and condimental feeds.

**Concentrated commercial feeding stuffs, J. D. TURNER and H. D. SPEARS** (*Kentucky Sta. Bul. 203 (1916), pp. 251-333*).—In addition to the usual notes on the enforcement of the state feeding-stuffs law, this bulletin gives grades for commercial corn and results of analyses of alfalfa meal, granulated bone, meat scrap, tankage, dried beet pulp, cracked corn, corn-feed meal, hominy feed, cotton-seed meal, linseed meal, rye feed, wheat bran, wheat middlings and shorts, brewers' dried grains, distillers' dried grains, and mixed and proprietary feeds.

The following table gives the amino-acid content of various protein substances, as determined by E. H. Nollau:

## Distribution of nitrogen in protein substances.

Kind of material.	Kind of nitrogen.								Total.
	Ammonia.	Melanin.	Cystin.	Arginin.	Histidin.	Lysin.	Amino of filtrate (mono-amino acid).	Non-amino of filtrate (prolin, oxyprolin, tryptophane, etc.).	
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>

[Animal husbandry studies] (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 41 (1915), pp. 32-34*).—Alfalfa hay was compared with oat straw for steer feeding for 118 days, the groups being given the same grain ration, as well as silage and the hay or straw 4:1. The steers in the alfalfa group made an average daily gain of 1.82 lbs. per steer, and those in the straw group 1.54 lbs. The alfalfa-fed steers made more rapid gains than those getting straw, but they consumed a great deal more feed, the gains made costing 11.51 and 11.37 cts. per pound, respectively. Financially, therefore, the results were very similar, though the steers fed alfalfa showed a little better finish than those fed straw.

An experiment was conducted to determine whether the addition of a high-protein feed, such as cottonseed meal, to the ration of steers receiving a low-protein, bulky ration would prove beneficial. One group was fed oat straw, corn silage, and meal from mixed home-grown grains, and a second group was fed the same bulky feed and the same kind and amount of mixed meal, with the addition of a small allowance of cottonseed meal constituting 20 per cent of the mixture. The group fed cottonseed meal made an average daily gain per steer of 1.58 lbs., and the other group, 1.54 lbs., but it is concluded that the feeding of cottonseed meal was not profitable.

Five lots of weanling pigs were fed as follows: Lots 1 and 2, commercial brands of tankage, with grain and water; lot 3, beef meal, grain, and water; lot 4, grain and water; and lot 5, skim milk and meal. These pigs made average daily gains per pig of 1.01, 1.06, 0.93, 1.01, and 1.09 lbs., costing per pound of gain, 4.33, 4.1, 4.48, 3.61, and 5 cts. for the respective lots.

In a second test five lots of 3-month-old pigs were fed as above. These pigs made average daily gains per pig of 1.14, 1.19, 1.1, 1.2, and 1.33 lbs., costing per pound of gain 4.23, 4.07, 4.76, 3.34, and 4.32 cts. for the respective lots.

Three lots of pigs were fed the same grain ration and an equal allowance of skim milk, lot 1 running on rape pasture, lot 2 on clover pasture, and lot 3 in dry pen. These pigs made average daily gains per pig of 1.01, 1.16, and 1.19 lbs., costing per pound of gain 4.4, 4.08, and 4.26 cts. for the respective lots.

**Feeding for beef in Alberta**, G. H. HUTTON and W. H. FAIRFIELD (*Canada Expt. Farms Sta. Bul.* 30, 2. ser. (1916), pp. 38, figs. 19).—This bulletin reports feeding experiments with steers conducted at the Lacombe and Lethbridge substations from 1909 to 1915, the results of which have for the most part been noted from the annual reports of the Canada Experimental Farms (E. S. R., 36, p. 65).

One hundred and two head of 2 and 3 year old cattle of average quality grazed on a fenced portion of well-watered pasture of native prairie grass at Lacombe during the summer of 1915 made an average gain of 358 lbs. per head. The grazing period in this test varied from 150 to 175 days.

**The characteristics of sheep wool and a new chemical method of determining its quality**, K. VON ALLWÖRDEN (*Ztschr. Angew. Chem.*, 29 (1916), No. 17, Aufsatzteil, pp. 77, 78, fig. 1).—This article treats of the structure, elasticity, quality, and general physical characteristics of wool fiber, and describes a chemical method for determining its quality.

**The fleece of coarse-wool sheep**, S. N. KOVALEVSKIÏ (*Sel'sk. Khoz. i Līsov.*, 250 (1916), Jan., pp. 20-67, figs. 31).—Experiments were undertaken to determine the moisture content, commercial weight, and fat content of wool, the effect of washing upon foreign substances, the loss through carbonization, and the fineness, elasticity, and strength of the fibers.

It was found that the wool close to the skin may successfully take the place of Merino wool, and even excel it in strength when tested for tearing. The hair of all kinds of wool is subject to polymorphism in the shape and position of epidermal scales. The coarser parts of the hair are covered with small scales disposed bridge-wise at its thicker parts, while at the thin places, which are generally void of core, the scales are in the shape of small laminae. The possibility of recognizing the race of sheep according to the scales of the hair can take place only after the study of all variations belonging to one and the same race. The bluish tint belonging to the Romanoff sheep is due to the two colors of the intermediary hair, which is dark at the top and gray at the bottom.

It is suggested that studies should be made of the under wool to determine its properties and its quantity. The caracul lower and upper wool ought to be experimented with as to the quantity of down in the wool. Scientific investigation of the wool should precede the establishment of sheep-breeding methods for the purpose of increasing the quantity and quality of wool.

**Sorrel color in horses**, L. P. McCANN (*Jour. Heredity*, 7 (1916), No. 8, pp. 370-372).—A study was made of records in the Belgian studbook covering a total of 427 matings and involving the color of over 1,250 animals.

"The chestnut by chestnut matings, while few in number, serve to demonstrate that sorrel is recessive to chestnut. In order to conform exactly to Mendel's law the offspring should be in the proportion of three chestnuts to one sorrel, and they do approach this proportion rather closely, being 13 to 5, respectively. There is a predominance of sorrels as compared to chestnuts in the Belgian breed studied, and it would therefore be expected that a larger number of the chestnut animals would be heterozygous for sorrel than if these two colors were present in equal numbers. This is more clearly shown in the chest-

nut by sorrel matings. Again considering the matter theoretically, if the two colors were present in equal numbers there should be fewer sorrels than chestnuts resulting from this cross, but there are 23 sorrels to 11 chestnuts. The same thing is brought out in the sorrel by bay matings. The sorrels and bays are present in about the proper proportions, but theoretically there should be a larger number of chestnuts.

"The bay by chestnut matings also substantiate the fact that sorrel is recessive to chestnut. If such were not the case the number of sorrels from this cross would be very small as compared to the others, but the result is 22 sorrels, 48 bays, 8 chestnuts, and 1 black.

"The sorrel by black matings give a result similar to the chestnut by black matings. The former gives 9 sorrels, 8 bays, 1 roan, 1 chestnut, and 6 blacks, and the latter, 1 sorrel, 2 bays, 1 brown, 1 roan, 1 chestnut, and 1 black, showing that sorrel and chestnut are qualitatively alike.

"The fact that the sorrel by sorrel cross gives sorrel offspring in practically 100 per cent of the cases is rather definite proof that sorrel is a unit character, and further, that it is recessive to all other colors. Therefore the breeder who is desirous of producing sorrel animals has an easier task than the one who desires to produce animals of a color other than sorrel. The former will be certain of getting sorrel colts as long as he has a sire and dam of sorrel color, while the latter can not be certain of the results from the cross of any other color."

### DAIRY FARMING—DAIRYING.

**Milk production cost accounts: Principles and methods,** C. W. LARSON (*New York: Columbia University Press, 1916, pp. 60*).—In this discussion the attempt is made to analyze each item of cost and also to apply the methods and practices of recognized authorities in factory cost accounting as far as they may be applied to milk production cost. The production cost of milk is discussed under the divisions feed; labor; indirect or overhead expenses, such as buildings, cattle, bedding, sire, etc.; and returns for calves and manure.

A method of precalculating feed costs is explained, which, it is stated, is quick and easy and can be applied to any system of feeding. In calculating the total cost of cattle in milk production the annual depreciation is obtained by the formula  $\frac{x-y}{n}$ , in which  $x$  represents the cost of the cow,  $y$  the sale price of discarded cow, and  $n$  the years of usefulness. To the amount thus obtained are added insurance, taxes, and interest on first cost of cow.

In summarizing cost and credits incident to milk production the author states that "under the conditions stated for each item, which include a particular size and kind of cow, producing 8,500 lbs. of 4 per cent milk with feeds at stated prices, with the system of management given, and with a good barn well equipped for the production of high-grade milk, cost records will show the following as actual costs in the production of milk: Feed, \$75.29; labor, \$27; buildings, \$8.24; cattle, \$9.21; bedding, \$3.25; sire, \$3.51; miscellaneous expenses, \$24.25; total cost, \$150.75; with credits of calves, \$3; manure, \$20; net cost per cow per year, \$127.75." On this basis the cost of production per 100 lbs. of milk is \$1.50.

"Under present prices of feed and labor a herd of high-producing cows will when properly managed return 5 per cent interest on the capital invested in a good plant, and an additional 5 per cent for services of the manager not included in regular labor charge. The average cow of the United States does not produce enough milk to pay the cost of production when managed under the same conditions and equipped to produce high-grade milk. Where the herd uses

feeds that can not be marketed, where a cheaper system of management is used, and where the cows are housed in cheaper buildings and given less care, they may pay the cost of production of milk. Under some conditions, summer dairying would be more profitable than the all-year practice. It does not pay to use intensive methods or winter grain feeding with low producing cows. The value of pasture for dairy cows has been underestimated."

A bibliography of related literature is given.

Labor requirements of dairy farms as influenced by milking machines, H. N. HUMPHREY (*U. S. Dept. Agr. Bul. 423 (1916), pp. 17, figs. 3*).—This is a study of the milking machine as a factor in the organization of the dairy farm. The data were obtained from 109 dairy farms in New York, representative of the intensive type of dairy farm, and from 160 dairy farms in Ohio, Michigan, and Illinois, representative of a mixed type of farm wherein dairying is combined with general farming. In each of the localities studied a number of mechanical milking machines was found.

The author summarizes the results of his studies as follows:

"The time saved by the use of the mechanical milker increases with increase in the size of the herd. With herds of 15 cows or less the average time required to milk a cow by hand is a fraction over 7 minutes; by machine a fraction under 5 minutes. With herds of over 50 cows it takes slightly under 7 minutes to milk a cow by hand and but 4.15 minutes by machine. With herds of over 50 cows one man with a machine milks on the average about 28 cows per milking as against 17 where the milking is done by hand.

"With increase in the size of the herd the cost per cow of hand milking changes very little, while the cost per cow of machine milking decreases rapidly. With herds of 15 cows or less the average cost of milking per cow by hand is \$10.91 per year as against \$10.45 in herds of 50 or more. With herds of 15 cows or less the average cost of milking per cow by machine is \$11.77 per year as against \$7.34 for herds of 50 or over.

"Although with the average small herd of 15 cows or less it costs more per cow to milk by machine than by hand, it does not follow that the machine is necessarily an unprofitable investment on all farms on which such small herds are kept. On 32 farms having herds of 15 cows or less the use of the mechanical milker was found to effect an annual saving in hired labor of \$2.63 per cow through the dropping of hands who had been kept primarily to do the milking."

Statistical weighting for age of advanced registry cows, C. W. HOLDAWAY (*Amer. Nat., 50 (1916), No. 599, pp. 676-687, figs. 2*).—Results are given of a study made for the purpose of determining whether the records of the various breed associations are consistent with their standards, and whether these standards can be used as a basis for weighting cows of different ages. Using 7-day records secured from the Holstein-Friesian Blue Book data are tabulated of 9,639 A. R. O. record female progeny of the Holstein bull, Paul De Kol, No. 14,634. From this population correlation coefficients were worked out, and curves were plotted for milk and fat production, showing (1) the requirements of the Holstein-Friesian Association, (2) the mean of the population, (3) the plus deviation from the mean, and (4) what the requirements ought to be according to the performance of the cows studied.

From an inspection of the curves of milk production the author points out "that the official requirements weight animals of an age from 18 to 21 months too heavily. The curve indicates that they are entitled to a reduction as great as for any other age. For the purpose of discouraging such early breeding, however, the requirements for this particular class should be prohibitive and they are. The production increases up to at least 6 years of age instead of 5, which the Holstein-Friesian Association requirements set as the maximum age

production. For this reason the 5- to 6-year-old animals and possibly the 7- to 8-year classes have an advantage over all other classes. A comparatively small number of animals made the requirement after 9 years of age, hence by selection, only the best animals were retained, thus drawing the curve down almost to a straight line."

Data are also tabulated and correlation coefficients worked out for 456 female A. R. O. progeny of the Holstein cow, Aaggie Grace, No. 2,618. These data agree in the essential points with those secured from the progeny of Paul De Kol.

**Liver meal for milch cows: Its influence on milk and dairy products,** H. ISAACHSEN (*Tidsskr. Norske Landbr.*, 23 (1916), No. 2, pp. 65-94).—On account of the high protein content liver and other detritus of fish is considered a valuable concentrated feeding stuff. Large amounts of it are exported to France and Germany.

In feeding experiments with cows, liver meal had a tendency to decrease the fat content of milk, and as the decrease lasts for several months it is of economic importance. No reason is assigned for the decrease of fat in the milk. The fat content in the milk of cows on pasture was greater than that of cows kept in barns. In the test 0.8 kg. of liver meal produced as much milk as 1 kg. of cottonseed meal. Two kg. of liver meal per cow daily for 15 days produced no bad results, and no change of taste in the milk or butter was noticed.

**A study of factors affecting the composition of sheep's milk,** J. FABRE (*Ann. École Nat. Agr. Montpellier, n. ser.*, 13 (1914), No. 2-3, pp. 113-120).—As a result of analyses of milk of Larzac sheep on different days, at different milkings during the same day, and of different portions of the same milking, the author concludes that for the most part the factors which affect the composition of cow's milk act in a like manner on the composition of sheep's milk. Under the influences studied the fat content of the milk showed the widest variation.

[**Dairy industry in New Zealand**], D. CUDDIE (*New Zeal. Dept. Agr. Ann. Rpt.*, 24 (1916), App., pp. 21-33).—A review is given of the dairy industry of New Zealand for the year ended March 31, 1916.

It is stated that the year was one of the most profitable ever experienced for the majority of farmers engaged in this industry. During the year 792,838 packages (396,419 cwt.) of butter and 591,810 packages (weight not given) of cheese were exported, being a decrease of 1.8 per cent of butter and an increase of 11.9 per cent of cheese as compared with the exports of the previous year.

**The milk supply of Paris before and during the war,** J. E. LUCAS (*Ann. Sci. Agron.*, 4, ser., 4 (1915), No. 10-12, pp. 422-453, fig. 1).—In addition to a statistical review of the milk supply of Paris since 1896, the author reports a study of the effects of the European war on the production, transportation, distribution, and cost of milk used in Paris. Suggestions for increasing the supply are included.

**The bacteriological examination of fresh milk,** J. RITCHIE (*Pub. Health [London]*, 29 (1916), No. 11, pp. 270-274).—Results are given of the bacteriological examination of 140 samples of milk from dairies throughout Dumfriesshire County, Scotland, during the year 1914. Of these samples 62 were found to contain under 50,000 bacteria per cubic centimeter and 78 samples over 50,000. The bacterial content of the milk was found to be correlated with the sanitary conditions under which it was produced. The author concludes that the value of the test for *Bacillus enteritidis sporogens* as applied to milk is extremely small.

**Bacterial testing versus dairy inspection,** C. E. NORTH (*Amer. Jour. Pub. Health*, 6 (1916), No. 6, pp. 569-578).—In this paper the author points out that the primary purpose of bacterial testing of milk by the use of the bac-

terial count is to determine its sanitary character, and that of dairy inspection to prevent the contamination of milk and to see that it is properly refrigerated. The growth of the two systems of inspection is reviewed. It is stated that up to the present time the tendency has been toward separate organizations for the two kinds of inspection with an undercurrent of competition between them. The author, however, believes that our present knowledge of the utility of the two methods justifies the establishment of more definite relationship, with complete cooperation between the two and a readjustment of their functions.

**Some observations on causes of high bacterial counts in market milk, H. D. PEASE** (*Amer. Jour. Pub. Health, 6 (1916), No. 6, pp. 563-568*).—The author concludes that where adequate field and laboratory control of milk supplies has been in operation for a number of years, high bacterial counts are generally caused through inefficiently cleaned apparatus and by the incubation of bacteria on moist surfaces of cans or other utensils, or that taking place in the product itself due to inefficient refrigeration. In localities where no supervision has been in operation and where the producers are more or less slovenly the rather uniform high bacterial counts found in milk are generally due to dirty conditions.

**The experience of New York City in grading market milk, L. P. BROWN** (*Amer. Jour. Pub. Health, 6 (1916), No. 7, pp. 671-677*).—The author gives an account of how New York City has dealt with the problem of controlling its milk supply. The essentials of New York's milk control system are described as (1) pasteurization of all milk except that intended for special uses, (2) in connection therewith the maintenance of bacteriological standards, (3) the labeling of all packages intended to go to the consumer, and (4) constant inspection and supervising of pasteurizing plants.

A statement is given of the chief successive steps that have been taken for the control of the city's milk supply which have led up to the system now in effect, together with a short description of the methods used in the inspection of pasteurization plants and equipment.

**The pasteurization of milk from the practical viewpoint, C. H. KILBOURNE** (*New York: John Wiley & Sons, 1916, pp. IV+248, figs. 34*).—This handbook for milk dealers, students in dairy schools, public officials having control of milk handling, and the general public, relates to the installation, operation, and control of pasteurizing plants. The subjects dealt with are pasteurization in general, heaters, holders, temperature controllers, and recorders, cleaning and cooling the milk, efficiency of various apparatus, and changes in the cream line due to the pasteurization of milk.

**Milk clarifiers, C. BAHLMAN** (*Amer. Jour. Pub. Health, 6 (1916), No. 8, pp. 854-857; abs. in Cream. and Milk Plant No. 5 (1916), No. 1, pp. 41, 42*).—As a result of bacteriological and chemical studies upon milk clarifiers made by the Cincinnati Department of Health, the author states that eight samples of raw milk averaging 1,312,000 bacteria per cubic centimeter showed an average increase of 27 per cent in bacterial content after being clarified. The ordinary sediment test applied to these samples of milk showed that the clarifier had removed all gross suspended dirt from the milk. The average weight of the material deposited in the clarifier was 1.6 gm. of moist sludge, equivalent to 0.6 gm. of dry material per gallon of milk. This material contained large numbers of bacteria and on analysis was found to consist largely of substances normally present in milk. Fresh certified milk also yielded a deposit when passed through the clarifier. The seemingly greater number of bacteria in clarified milk is thought to be due to the breaking apart of clumps of bacteria by the mechanical action of the clarifier.

Some observations on homogenized milk and cream, H. B. BALDWIN (*Amer. Jour. Pub. Health*, 6 (1916), No. 8, pp. 862-864, figs. 2).—The author notes the development and occasional fraudulent use of the process of homogenization in the milk industry, and gives the results of two sets of measurements of fat globules in samples of homogenized cream from two different machines working under pressures of from 700 to 4,000 lbs. per square inch.

The degree of homogenization was found to be generally increased with the pressure, and in one of the machines the destruction of fat globules was so great that no spherical forms could be observed through a one-twelfth in. oil-immersion objective. The diameter of most of the homogenized fat globules ranged between 0.001 to 0.002 mm. in diameter, whereas the majority of normal milk fat globules range in diameter from 0.005 to 0.006 mm.

Condensed milk in Bermuda, S. W. EELLS (*U. S. Dept. Com., Com. Rpts., No. 241 (1916), pp. 168, 169*).—The author states that Bermuda annually imports about 720,000 cans of condensed milk, of which about 15 per cent is unsweetened or evaporated. On account of poor pastures and the cost of fodder the prospects for the production of fresh milk on the islands are not good. Evaporated milk stands the climate well. The American brands of unsweetened condensed milk are considered best by most dealers, though there is a prejudice among consumers in favor of Canadian and European brands. Nearly all the sweetened condensed milk comes from Europe, but some is now imported from Canada.

Suggestions for the manufacture and marketing of creamery butter in the South, R. C. POTTS and W. WHITE (*U. S. Dept. Agr., Off. Sec. Circ. 66 (1916), pp. 11*).—This circular contains practical suggestions on the management of creameries and the manufacture and marketing of creamery butter in the South.

## VETERINARY MEDICINE.

Report of the veterinary director general for the year ended March 31, 1915, F. TORRANCE (*Rpt. Vet. Dir. Gen. Canada, 1915, pp. 131, pls. 7, figs. 3*).—Following the main part of this report (pp. 3-33) dealing with the work of the year on the more important diseases of animals and import testing are 17 appendixes. Among the more important of these are the report of the pathologist at the biological laboratory, Ottawa (pp. 71-76), including papers on The Care, Sanitation, and Feeding of Foxes in Captivity (pp. 77-94) and An Economical Measuring Device (pp. 98, 99), by C. H. Higgins; and Is *Leucocytozoon anatis* the Cause of a New Disease in Ducks? by A. B. Wickware (pp. 95-97), previously noted from another source (*E. S. R.*, 33, p. 483), as well as later work (*E. S. R.*, 36, p. 85); report of the pathologist at the veterinary research laboratory at Lethbridge, Alberta (pp. 100, 101), including a report on Dourine and the Complement-Fixation Test (pp. 101-119), by E. A. Watson; and a report of the pathologist at the research laboratory at Agassiz, British Columbia, in which S. Hadwen deals briefly with tick paralysis, etc. (pp. 120-123).

Annual report for 1914 of the principal of the Royal Veterinary College, J. McFAYDEAN (*Jour. Roy. Agr. Soc. England, 75 (1914), pp. 252-269, figs. 4*).—This report deals principally with the occurrence of and work with anthrax, glanders, foot-and-mouth disease, sheep scab, swine fever, tuberculosis, contagious abortion, and Johne's disease. Considerable attention is given to the treatment of the last-mentioned disease, data relating to which have been previously noted (*E. S. R.*, 35, p. 76).

A new model of double pipette holder and the technique for the isolation of living organisms, F. HECKER (*Jour. Infect. Diseases, 19 (1916), No. 3, pp.*

306-314, figs. 6).—A new apparatus and its use and manipulation in the isolation of living organisms are described in detail.

Lupines as poisonous plants, C. D. MARSH, A. B. CLAWSON, and H. MARSH (*U. S. Dept. Agr. Bul. 405 (1916), pp. 44, pls. 4, figs. 2*).—The introductory part of this bulletin gives a summary of knowledge of lupines as poisonous plants and accounts of their distribution, common names, alkaloids, etc. The second part (pp. 7-28), which deals with experimental work, takes up pharmacological investigations by Sollmann, field experiments with lupines, and laboratory experiments with extracts of lupine seed upon mice. The third part (pp. 28-42) is devoted to a discussion and general conclusions.

"An investigation by Sollmann showed the presence of alkaloids in American lupines, and pointed to the probability that most, if not all, the poisoning of live stock in America was due to these alkaloids and not to ictrogen. Extended field work has verified the conclusions of Sollmann and has shown that all aerial parts of the lupines examined are poisonous, the seeds being the most toxic, then in order the pods and leaves. This has been confirmed by preliminary experiments with extracts upon mice.

"The toxic substance is excreted by the kidneys; the intoxication is not cumulative, and animals may eat comparatively large quantities with no ill results, if the toxic limit is not reached at any one time. Inasmuch as the toxic and lethal limits are nearly the same, the prognosis for poisoned animals is not favorable. There is no form of remedial treatment that can be used advantageously for range animals. Poisoning in most cases can be avoided, even where the plant is abundant, by careful handling of the flocks, especial care being taken to see that hungry sheep are not grazed on fields where there is much lupine."

A list of 29 references to the literature is included.

Studies on the action of glycerin.—I, The hemolytic action of glycerin in vitro and in vivo, I. SIMON (*Arch. Farmacol. Sper. e Sci. Aff.*, 20 (1915), Nos. 3, pp. 120-144, figs. 4; 4, pp. 145-165, fig. 1; *abs. in Chem. Zentbl.*, 1916, I, No. 1, p. 25).—The blood of cattle and rabbits was hemolyzed by glycerin in all concentrations. The time necessary for hemolysis was found to increase with increasing concentrations of glycerin, and to reach a maximum at a concentration of 55 per cent for cattle blood and 50 per cent for rabbit blood. With increasing concentrations of the glycerin the rate of hemolysis increased rapidly.

Subcutaneous and intraperitoneal injections in rabbits produced serious local lesions and a general toxicity. When the amount of glycerin injected exceeded 2.5 gm. per kilogram of body weight a hemoglobinuria resulted, regardless of the strength of the glycerin injected.

The theory of the action is discussed.

A contribution to the action of amino acids, peptids, and proteins on hemolysis by cobra venom, E. ZUNZ and P. GYÖRGY (*Jour. Immunol.*, 1 (1916), No. 5, pp. 531-569).—Detailed experimental results are submitted which show that the effects of amino acids, peptids, and proteoses on cobra venom hemolysis vary according to the species of blood corpuscles used and also the amount in the blood-venom mixture.

"The hemolytic action of cobra venom on the red cells of guinea pig's blood is markedly hastened and increased in intensity by phenylglycocoll, leucin, glycytryptophan, and protoalbumose. The hemolysis is produced more quickly in the presence of large quantities than it is with small amounts of phenylglycocoll and leucin. Heteroalbumose tends slightly to increase the intensity of the hemolysis; alanin, on the contrary, diminishes it a little. Glycocol and particularly diglycin, triglycin, and leucylglycin inhibit the hemolysis in direct proportion to their concentration.

"In the presence of 0.1 cc. of fresh guinea pig's serum the accelerating action of protoalbumose and of glycylytryptophan and the inhibiting action of the strong concentrations of diglycin, of triglycin, and of leucylglycin is hardly greater than that of the weaker concentrations. Heteroalbumose shows marked effects. The presence of inactive serum exercises a protective action upon the blood corpuscles. It does not interfere with the acceleration of the hemolysis by phenylglycocoll, but it does diminish the adjuvant effects of glycylytryptophan and leucin and it almost completely annihilates those of protoalbumose. It weakens considerably the marked effects of diglycin. Glycocoll and heteroalbumose appear no longer to exercise any influence on the hemolysis."

The influence of the amino acids, peptids, and proteoses upon human blood was similar to that exercised by the same products on the blood of guinea pigs. Similar observations were also made of the effect on the hemolysis of dog, rabbit, sheep, calf, and ox blood.

**Anaphylaxis produced by sensitization through the vagina.** A. HAMM (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 1, pp. 1-11*).—Experiments are reported which show that guinea pigs can be readily sensitized by the introduction of the antigen into the vagina. Horse serum as well as micro-organisms isolated from the mucous membrane of the vagina were found to be absorbed and produced pronounced symptoms of anaphylaxis. True parasites, semiparasites, or true saprophytes produced the same result. The reinjection was made intravenously.

**The use of polyvalent sera.** L. CUVELLIER (*Rev. Soc. Med. Vet. [Buenos Aires], 1 (1915), No. 4-5, pp. 254-264*).—The action of polyvalent sera in wound treatment is briefly discussed, and the successful treatment of cases in wounded horses reported in detail.

**A case of anthrax.** G. G. REINLE and R. A. ARCHIBALD (*Jour. Infect. Diseases, 19 (1916), No. 5, pp. 718-720, pl. 1*).—A case of anthrax in a veterinarian who had examined a cow which had died with the disease, together with detailed clinical data, is reported.

The eosinophils were found to be an important factor in the blood picture throughout the disease. After the administration of antianthrax serum a marked eosinophilia was observed. When the clinical manifestations showed signs of relapse during the course of the disease the eosinophilia disappeared. It reappeared, however, when the situation was relieved, and then gradually subsided as convalescence progressed. The important rôle played by the antianthrax serum in bringing about the recovery of the patient is pointed out.

**Is *Bacillus abortus* pathogenic for human beings?** L. H. COOLEIDGE (*Jour. Med. Research, 34 (1916), No. 3, pp. 459-467*).—The author has failed to find proof that *B. abortus* is pathogenic for human beings. "It is possible to cause antibodies for *B. abortus* to appear in the blood serum of adults by feeding a milk which is naturally infected with *B. abortus* and which contains the *B. abortus* antibodies. Antibodies appearing as above apparently indicate a passive immunity due to the absorption in the large intestine of the antibodies present in an infected milk."

**The bull as a disseminator of contagious abortion.** F. B. HADLEY and H. LOTHE (*Jour. Amer. Vet. Med. Assoc., 50 (1916), No. 2, pp. 143-156*).—The authors' investigations are summarized as follows:

"Bulls may become infected with the abortion bacilli. Bulls with systemic infections used in the experiments were incapable of disseminating the abortion disease to virgin, abortion-free heifers by cohabitation. Bulls appear to possess a sexual or individual immunity to abortion infection that renders them less susceptible than cows and induces a more benign form of the disease. Bulls, when infected, have the ability to attenuate the infecting micro-organ-

isms in their bodies in a relatively short time, so that they will be safe for the service of noninfected cows. Cows usually acquire the abortion disease from other sources than the genitalia of bulls at the time of service."

The causative organism of foot-and-mouth disease, H. STAUFFACHER (*Ztschr. Wiss. Zool.*, 115 (1916), No. 1, pp. 1-57, pls. 2, figs. 29; *abs. in Jour. Bact.*, 1 (1916), No. 3, pp. 353-355).—This is a report of investigations at Frauenfeld, Switzerland, in which the author found an organism in the diseased tissues and blood of animals suffering from foot-and-mouth disease, to which the name *Aphthomonas infestans* is given.

Minute polymorphic structures with an average length of  $1\mu$  were found in the lymph and blood of all the 26 infected animals examined, but were never found in similar tissues of normal, healthy animals. The same bodies were found in the freshly-drawn blood, both free in the plasma and within the erythrocytes, of infected animals, thus excluding the possibility that they are products of nuclear and cellular degeneration brought about by the disease. The author has grown these bodies in the condensation water of blood agar culture media and has observed many developmental stages, has inoculated normal cattle with the organisms from the artificial cultures and produced the disease, and then recovered the organisms from the diseased tissues of the inoculated animals, thus having fulfilled Koch's postulates for the determination of a causative organism. Two distinct types were observed: One, shorter and thicker, had the characteristic appearance of a flagellated protozoon, with a lancet-formed body which becomes sharply attenuated and drawn out into a long flagellum; the other was much longer and more thread-like.

It is pointed out that the intracellular bodies with their varied forms, which, however, are reducible to one general type, are strikingly suggestive of Leishmania, particularly *L. donovani* of kala-azar.

The review is by G. N. Calkins.

Investigation on the presence of the tubercle bacillus in milk, E. E. CHARLES (*Rev. Soc. Med. Vet. [Buenos Aires]*, 2 (1916), No. 1-3, pp. 37-60).—In a hygienic study of the milk supply of Buenos Aires tuberculous lesions were produced by the inoculation of samples of the common milk supply in only 1 guinea pig out of a series of 38. It is indicated, however, that these negative results should not be considered conclusive, especially in public health institutions. The literature and theoretical and experimental aspects of the subject are discussed in detail.

The clinical value of complement fixation in tuberculosis, H. R. MILLER (*Jour. Amer. Med. Assoc.*, 67 (1916), No. 21, pp. 1519-1521).—Tabular data of the results of 1,012 cases of tuberculosis tested with the antigen prepared as previously noted (*E. S. R.*, 36, p. 81) are reported, and the results discussed.

It is concluded in general that the reaction is practically always positive in active tuberculosis; nontuberculous and normal patients react negatively; the sera of syphilitics who have no clinically active tuberculosis are negative; and the test is, as a rule, negative in arrested cases. "The von Pirquet and intradermic tuberculin tests and the complement-fixation reaction are not identical or similar diagnostic procedures, since the former indicates the existence of a tuberculous lesion whether old and arrested or active, while the latter points clearly to the presence of some active focus."

The complement-fixation test carried out with the antigen described is considered to be a distinct aid in the diagnosis of early tuberculosis and in the detection of the disease when the condition is obscure.

A contribution to the chemotherapy of tuberculosis.—First experimental report, G. KOGA (*Jour. Expt. Med.*, 24 (1916), No. 2, pp. 107-147, pls. 5).—Detailed experimental results of the treatment of tuberculous guinea pigs with

albumin-free tuberculin, iodotuberculin, and compounds prepared from copper salts and cyanids, designated as liquids *A*, *B*, *C*, and *D*, are reported.

The effect of a single injection of these liquids upon the tuberculous lesions was found to be either negative or inconspicuous. After repeated injections, however, the congestion and leucocytic infiltration about the lesions decreased markedly, the cheesy material resulting from degeneration of the lesions and other degeneration products appeared to be in a process of absorption, and young connective tissue was being actively produced in the periphery.

While these changes were taking place the number of the bacilli was also being reduced until finally they could no longer be detected on microscopical examination. "Hence it appears that while the preparation may lack bactericidal action in vivo powerful enough to destroy all the bacilli at one injection, yet repeated infusions may nevertheless bring about the destruction of all the bacilli and the modification of the tubercular lesion into that of the suspended stage or even into the healed condition. Whether, therefore, the preparation brings about these results directly by killing the bacilli or indirectly by favoring the healing processes of the body, nevertheless it has power to inhibit the growth of or annihilate entirely the bacilli in vivo."

So far as microscopic examination was concerned sterility of the tissues was obtained. Emulsions of the various organs of treated animals injected into healthy animals did not, however, yield consistent results, so that absolute sterility in all animals was not obtained.

**A contribution to the chemotherapy of tuberculosis.—First clinical report, G. KOGA (*Jour. Expt. Med.*, 24 (1916), No. 2, pp. 149-186, pls. 6, figs. 20).**—A number of cases are reported in detail which indicate that the preparation "liquid *D*," noted above and designated as "cyanocuprol," "greatly improves or apparently cures pulmonary and surgical tuberculosis in the first and second stages, and that it seems also to produce beneficial effects upon the disease in the third stage."

It is indicated that the duration of the beneficial effects must be established more definitely by further observations.

**The etiology of bovine metritis, B. EGGINK (*Aetiologie der Metritis beim Rinde. Inaug. Diss., Univ. Bern, 1914, pp. 75*).**—The author briefly reviews the classification of uterine diseases as arranged by earlier investigators, and discusses the general considerations in regard to endometritis, puerperal infection and intoxication, etc. The etiology of uterine infections, bacteria found in the bovine genitals, investigation of a number of cases of metritis, the relation between metritis and post-partum polyarthrititis, and the serum treatment of uterine diseases are also discussed.

It is concluded that the previously accepted classification of the various forms of metritis is a purely clinical one. Considered from the etiological standpoint there is really no difference between the various forms. They are considered to be caused by the same micro-organisms, and under the term metritis every infection of the uterus (plus its contents) should be included. There are always a greater or lesser number of virulent organisms present in the uterus which exercise their pathogenic influence either by local action on the tissues, by the production of a general toxemia, or by a combination of both. Post-partum polyarthrititis is considered always to be secondary and the result of an earlier uterine infection by specific organisms.

Serum treatment in metritis, especially the injection of *Streptococcus pyogenes* antiserum as a prophylactic after difficult parturition and also as a curative agent in active infections, is recommended.

A bibliography of 69 references is included.

*Bacterium pyogenes* associated with a case of multiple arthritis in a hog, A. R. WARD (*Abs. in Jour. Bact.*, 1 (1916), No. 1, p. 114).—It is pointed out that polyarthritis of swine is frequently encountered in post-mortem inspection of meat. *B. pyogenes* was isolated in pure culture from a case showing various stages of articular involvement from the early stages of synovitis to later stages showing erosion of articular cartilage, exostosis, and ankylosis of the joints.

Swine erysipelas and hog cholera, A. A. FERREIRA (*Doenças Rubras dos Suínos e a Peste Suína. Lisbon: Assoc. Cent. Agr. Portuguesa, 1915, pp. 32, figs. 6*).—This pamphlet briefly enumerates common and rare contagious diseases of swine in Portugal and briefly discusses swine erysipelas. Hog cholera in regard to its prevalence, morbidity, diagnosis, infectivity, and immunization (single or simultaneous vaccination) is also discussed.

Agglutinins in hog-cholera immune serum for *Bacillus suispestifer*, H. WEHRBEIN (*Jour. Infect. Diseases, 19 (1916), No. 3, pp. 446-451*).—Tabular data of the agglutinins for *B. suispestifer* in 100 hog-cholera immune sera, in the sera of 8 normal pigs, and in 8 sera of virus pigs are submitted. An experiment to ascertain the connection between the agglutinin titer for *B. suispestifer* and the antibodies in a hyperimmune serum is also reported.

Further studies on the virulent salt solution used in the production of hog-cholera serum, W. S. ROBBINS (*Jour. Infect. Diseases, 19 (1916), No. 5, pp. 708-711*).—Experimental data reported indicate that "virulent salt solution is not nearly so virulent as virulent blood, and that while it is efficient in hyperimmunizing by the subcutaneous method it would no doubt be impractical in the intravenous method because of the difficulty of injecting enough of it intravenously to produce very potent serum. Even if it is used in mixture with virulent blood the amount of the mixture required to produce good serum would be unusually high."

See also a previous note by Graham and Himmelberger (*E. S. R.*, 34, p. 680).

Lameness of the horse, J. V. LACROIX (*Chicago: Amer. Jour. Vet. Med.*, 1916, pp. 271, figs. 62).—The first section (pp. 15-35) of this work deals with the etiology and occurrence of lameness; the second section (pp. 37-53) with diagnostic principles; the third section (pp. 55-183) with lameness in the fore leg; and section four (pp. 185-261) with lameness in the hind leg.

The effect on horses of feed heavily inoculated with *Bacillus coli* isolated from oat hay, R. GRAHAM and L. R. HIMMELBERGER (*Abs. in Jour. Bact.*, 1 (1916), No. 1, pp. 115, 116).—Studies reported by Rogers, Clark, and Evans (*E. S. R.*, 33, p. 631) on the occurrence of the colon bacteria on grains led the authors to conduct investigations with a view to discovering a type pathogenic or virulent for live stock (see *E. S. R.*, 34, p. 681).

"In no case were we able to produce death by feeding, but the condition in the experimental horses was such as to suggest that feeds contaminated extensively with colon bacilli lower animal vitality and render the animal more susceptible to other injury. . . . It is evident from these observations that the occurrence of *B. coli* as isolated from grain which was the causative factor of so-called 'forage poisoning' bears no primary relation to the disease resulting from the feeding of the oats, but from a sanitary standpoint it seems advisable to protect animal feeds from *B. coli* contamination in so far as possible."

Sclerostome parasites of the horse in England, I, C. L. BOULENGER (*Parasitology, 8 (1916), No. 4, pp. 420-439, pl. 1, figs. 7*).—This first part deals with three species of the genus *Triodontophorus*, of which two are described as new to science, and one species of the genus *Oesophagodontus*. A bibliography of 19 titles is included.

Notes on the histopathology of the intestines in young chicks infected with *Bacterium pullorum*, G. E. GAGE and J. F. MARTIN (*Jour. Med. Research*, 34 (1916), No. 2, pp. 149-155).—"In this experiment, using cultures from several sources, without exalting their virulence, it was possible to produce typical bacillary white diarrhea. Death resulted from three to ten days after the inoculation.

"Stained sections were made from various levels of the Intestinal tract of all dead birds. From the study of the sections there was revealed marked injury to the mucosa, associated with hyperemia, hemorrhagic exudation, and leucocytic infiltration. In the individuals in which the disease had run a longer course there are exhibited processes of regeneration. There is in many instances a thickening of the intestinal wall. There is a marked fibroblastic proliferation, and wherever there is any of the columnar epithelium intact there is active secretion of mucus. Therefore, with these pathological conditions associated together, and repeated observations confirming them, it is evident that the important histopathological conditions in the intestines in young chicks dead of *B. pullorum* infection correspond to either an acute or beginning chronic condition of catarrhal inflammation."

The poisonous effects of the rose chafer upon chickens, G. H. LAMSON, JR. (*Jour. Amer. Assoc. Instr. and Invest. Poultry Husb.*, 2 (1916), No. 9, pp. 65, 66).—Previously noted from another source (E. S. R., 35, p. 489).

### RURAL ENGINEERING.

The flow of water in wood-stave pipe, F. C. SCOREY (*U. S. Dept. Agr. Bul.* 376 (1916), pp. 96, pls. 14, figs. 7).—This is a report of 64 experiments on the flow of water in 16 different wood-stave pipes ranging in diameter from 8 in. to 13.5 ft., and of the collection and analyses of available records of all previous experiments of a similar character by others. In the experiments 13 of the pipes ranged from 8 in. to 4 ft. in diameter; one was 6.5 ft., one 12 ft., and one 13.5 ft. in diameter. Six pipes were of the machine-banded type, put together in lengths, and ten were of the continuous-stave type. Mean velocities ranged from less than 1 ft. per second to more than 8 ft. per second.

The analysis of all experiments reviewed, which combined reached a total of 286, indicated that an exponential formula most nearly applies to the flow of water in wood-stave pipes. It was found "(1) that Kutter's formula with a constant value of  $n$  does not apply to flow in wood-stave pipes running full, (2) that  $n$  decreases with an increase in velocity in a given size of pipe and increases with the size of pipe for a given velocity, varying from less than 0.01 for small pipes at high velocities to more than 0.014 in large pipes, (3) that this variation in  $n$  is so marked and complicated as to render the use of Kutter's formula inadvisable." On the basis of the analysis a new formula for flow of water in wood-stave pipes either jointed or of continuous stave construction is presented as follows:

$$H=7.68d^{-1.17}V^{1.8}=0.419D^{-1.17}V^{1.8}$$

becoming

$$H=\frac{7.68 V^{1.8}}{d^{1.17}}=\frac{0.419 V^{1.8}}{D^{1.17}}$$

In this formula  $H$  = the friction loss per 1,000 linear feet of pipe,  $V$  = mean velocity of water in feet per second,  $d$  = the mean inside diameter of the pipe in inches, and  $D$  = the mean inside diameter of the pipe in feet. It was found

that the application of this formula "meets (within 1 per cent) the mean of all observations and the mean capacity of all wood pipes upon which experiments have been made."

General conclusions regarding the capacity of wood-stave pipes are drawn as follows: "A very conservative factor of safety should be used where a guaranteed capacity is to be attained. . . . The data now existing do not show that the capacity of wood-stave pipe either increases or decreases with age. This statement does not consider sedimentation, a purely mechanical process. If silted waters are to be conveyed, the pipe should be designed for a working velocity of from 5 to 10 ft. per second. If sand is present in the water, the design should be for a velocity of about 5 ft. per second, which will be high enough to carry out a large part of the sand and at the same time not so high as to seriously erode the pipe. The better method is to remove the sand by sumps or other means. Air should be removed from the intake end of every pipe line, especially when the capacity load is approached. Wood pipe will convey about 15 per cent more water than a 10-year-old cast-iron pipe or a new riveted pipe, and about 25 per cent more than a cast-iron pipe 20 years old or a riveted pipe 10 years old."

An appendix devoted to abstracts of descriptions of experiments made by agencies other than the Division of Irrigation Investigations of the U. S. Department of Agriculture is included, together with a discussion of the flow of water in wood-stave pipe, by G. S. Williams, T. A. Noble, D. C. Henny, E. A. Moritz, E. W. Schoder, and L. M. Hoskins.

**New method of deriving weir formulas**, T. R. RUNNING (*Engin. News*, 76 (1916), No. 15, pp. 695, 696, figs. 4).—A new method of determining the rate of flow of water over weirs, especially adapted for experiments on the flow of water through pipes, is described as developed at the University of Michigan.

The main advantage of the method is that it requires only a single experiment for determining the rate of flow of water over a weir for different heads and is applicable to weirs of high as well as of low heads. The apparatus for recording the time and head is described, and the derivation of the weir formula on the basis of head and time is mathematically presented.

**Design of small lined canals** (*Jour. Electricity*, 37 (1916), No. 15, pp. 279, 280, figs. 3).—Curves showing the carrying capacities of small wooden flumes in second feet, miner's inches, and gallons per minute are given. The flumes vary in area of water cross section from 0.5 to 3 sq. ft. and have a fall in feet per 1,000 ft. of from 0.5 to 20. The curves are based on a value of "n" in Kutter's formula of 0.015. "The carrying capacity of small concrete flumes or lined ditches can also be obtained from these curves, as there is usually little difference in the friction factor."

**Surface water supply of Pacific basins in Washington and upper Columbia River Basin, 1913** (*U. S. Geol. Survey, Water-Supply Paper 362-A* (1916), pp. VI+264, pls. 2).—This report, prepared in cooperation with the States of Washington, Montana, and Idaho, presents the results of measurements of flow made on the Quinault River, Puget Sound, and upper Columbia River drainage basins during 1913.

**Rogue River Valley Project and Willamette Valley Investigations**, J. T. WHISTLER and J. H. LEWIS (*Oreg. Cooper. Work, Dept. Int. U. S. Reclam. Serv.*, 1916, Feb., pp. 111, pls. 15).—This report was prepared in cooperation with the State of Oregon. The part covering the Rogue River Valley Project deals with the irrigation and water supply of that portion of the Rogue River Valley above Tolo, and more especially the area in the immediate vicinity of Ashland and Medford. The average texture of soils of the area is that of a clay loam. "A duty of 1.5 acre-feet delivered on the land has been adopted. It is based

on the assumption that fruit will always be the predominating crop in the valley. . . .

"The Willamette Valley investigations relate to no particular project in the drainage area of Willamette River, but were made to locate in a general way any projects which existing conditions might render feasible and to look into the possibilities of developing the known productive qualities of the valley soils by irrigation, either through pumping or by storing the waters of tributary streams and distributing by gravity to the lands. The lands whose irrigation possibilities were examined extend from Canby at the mouth of Molalla River to the head of Willamette River above Cottage Grove and include the area in the immediate vicinity of Portland. It was found feasible to irrigate approximately 100,000 acres at the present time. . . . The average economic duty of water which seems to be indicated for the valley as a whole is 8 in. delivered to the land, varying with local conditions of soil and crops. . . . Drainage is found to be one of the important features in connection with any proposed irrigation in the valley and must be included in any consideration of practical construction and cost."

**John Day Project: Irrigation and drainage, J. T. WHISTLER and J. H. LEWIS** (*Oreg. Cooper. Work, Dept. Int. U. S. Reclam. Serv., 1916, Feb., pp. 185, pls. 47*).—This report, prepared in cooperation with the State of Oregon, presents the results of investigations consisting of the following: "(1) Detailed surveys and estimates of the main project considered, which provides for the irrigation of 122,000 acres by storage of 112,000 acre feet of water at Dayville Reservoir and 133,000 acre feet at Carty Reservoir, and requires about 75 miles of supply canal diverting from John Day River 17 miles below Thirty Mile Creek. The estimated cost of this development is approximately \$125 per acre. (2) Reconnaissance surveys and estimates to determine the practicability of diverting waters of the north fork of John Day River into Columbia River basin, looking toward the irrigation of Shuttler Flats and any other lands which it might be found feasible to cover. . . . (3) Consideration of plans to irrigate the land within reach by pumping from Columbia River. The estimated cost of the cheapest pumping project considered is \$52 per acre for 50,000 acres, with an annual charge for operation and maintenance of about \$8.50."

"The lands considered in the irrigation development proposed lie along Columbia River between John Day River on the west and Umatilla River on the east, and are in Gilliam, Morrow, and Umatilla counties, Oregon. . . . The minimum run-off of record of John Day River at McDonald is 737,000 acre feet, and the average for 11 years of complete record is 1,433,000 acre feet, all of which would be available for storage. . . .

"The soils are generally of a sandy character. Of the 122,000 net acres 36 per cent is regarded as very desirable for irrigation. This soil averages from 3 to 5 ft. in depth and is underlaid with hardpan or some impervious material. Fifty-five per cent is fairly desirable for irrigation, the soil averaging from 2 to 3 ft. in depth and being generally underlaid by basalt. Nine per cent is not attractive for irrigation at the present time, the soil consisting of coarse sand with some silt to a depth of about 12 in., increasing to clean coarse sand of unknown depth. . . .

"A duty of 3 acre feet per acre has been adopted, based on the assumption that from 30 to 40 per cent of the irrigated land will be used for the growing of fruit, berries, and vegetables, and that 10 per cent will be taken up by roads and building space. Some of the land will require an amount of water greatly in excess of 3 ft., but it is believed that this amount will be found ample for the mean use when the project is fully developed."

The type of colon bacillus occurring in surface waters, L. A. ROGERS (*Abs. in Jour. Bact.*, 1 (1916), No. 1, p. 82; *Chem. Abs.*, 10 (1916), No. 16, p. 2115).—A collection of 137 cultures of the colon type isolated from waters of greatly varying degrees of contamination was separated into two distinct groups. One of these included about one-third of the cultures and was evidently identical with the type which has been found to include from 95 to 99 per cent of the colon bacilli of bovine and human feces. This type was found occasionally in springs in which there was no evident source of contamination, but was especially abundant in rivers and streams usually considered to be polluted with sewage.

The second group which occurred in practically all waters examined was identical with a type which, while it responds to all of the usual tests for *Bacillus coli*, occurs in feces in relatively small numbers. Cultures isolated from grains belonged almost exclusively to this type. The significance of this type in water can not be determined, but the characteristic fecal colon type can be demonstrated in polluted water with reasonable certainty.

Running water possible for every country home, R. U. BLASINGAME (*Ala. Polytech. Inst. Ext. Serv. Circ. 4* (1916), pp. 31, figs. 7).—This circular describes and illustrates five water-supply systems especially adapted to Alabama farm-home conditions and varying in price from \$18.50 to \$126.14. "Each system has been so designed as to allow the addition of further equipment at any time funds may become available." Bills of material are also included. An arrangement whereby the water tank may be placed on a concrete or tile silo is described. "This practice is becoming rather general in Alabama, and is economical, in that it eliminates the expense of a tower."

First report of the state engineer of New Mexico, J. A. FRENCH (*Rpt. State Engin. N. Mex.*, 1 (1912-1914), pp. 120, pls. 15).—This report covers the period July 12, 1912, to Dec. 1, 1914, and is divided into two main sections. One relates to the supervision of the work delegated to the State Highway Commission from the time it superseded the Territorial Road Commission, September 8, 1912, and includes the work accomplished and contemplated, with a statement of the receipts and expenditures of funds by the commission; and the other concerns the work of the state engineer, as provided by law, relating to irrigation, hydrographic surveys, power projects, pumping plants, steam gaging, Carey Act projects, irrigation districts, improvement to the Rio Grande, street paving in Santa Fe, the capitol sewer system, and well digging on state lands.

Annual report of the state engineer and surveyor of the State of New York for the fiscal year ended September 30, 1915, F. E. WILLIAMS (*Ann. Rpt. State Engin. and Surveyor N. Y.*, 1915, vols. 1, pp. 378, pls. 75; 2, pp. 428, pls. 10).—This report deals with the work and expenditures of the state engineer's office for the year 1915, and reports the results of measurements of flow made on streams in the State during 1915.

Third biennial report, State Road Commission 1913-14 (*Bienn. Rpt. State Road Com. Utah*, 3 (1913-14), pp. 297, pls. 33, figs. 89).—This report summarizes the engineering and other work and expenditures of the commission for the years 1913 and 1914.

[First annual report State Road Bureau West Virginia], A. D. WILLIAMS ET AL. (*Ann. Rpt. State Road Bur. W. Va.*, 1 (1914), pp. 397, pls. 25, figs. 12).—This report for the year ended June 30, 1914, embraces tables of costs, cost data, expenditures, and assessments of counties on which road taxes have been levied, and the amount of tax raised in each of the funds by districts and by counties, also opinions of the attorney general on subjects of law pertaining to roads, orders pertaining to bonds, and a brief description of the road work being done in the State.

New road laws of Oklahoma as passed by the legislatures of 1915 and 1916 (*Oklahoma City, Okla.: The Boardman Co., 1916, pp. 80, pls. 2*).—The text of the laws is given.

Road maintenance and its significance, E. W. JAMES (*U. S. Senate, 64. Cong., 1. Sess., Doc. 429 (1916), pp. 8*).—This is an address delivered at the seventh annual convention of the Southern Commercial Congress.

The construction of roads and pavements, T. R. AGG (*New York: McGraw-Hill Book Co., 1916, pp. VII+432, pl. 1, figs. 115; rev. in Engin. Rec., 74 (1916), No. 14, p. 418*).—This book is a concise presentation of approved practice in the construction of roads and pavements and of the principles involved, and includes numerous tables and typical designs and specifications. It contains the following chapters:

The development of highway systems, surveys and plans for roads and pavements, the design of rural highways, the construction and maintenance of earth roads, testing nonbituminous road materials, sand-clay roads, gravel roads, water-bound macadam roads and pavements, concrete roads and pavements, vitrified-brick roads and pavements, wood-block pavements, stone-block pavements, bituminous road and pavement materials, dust layers and bituminous carpets, penetration and mixed macadam roads and pavements, sheet asphalt and asphaltic concrete surfaces, selection of type of surface for rural highways, selection of type of pavement surface, the design of pavements, and tests for bituminous road and paving materials.

Should wider joints be provided in concrete roads laid late in the season? H. S. VAN SCOYOC (*Engin. Rec., 74 (1916), No. 16, pp. 465, 466, figs. 2*).—The results of an inspection of 2,071 joints of  $\frac{1}{4}$ -in. width in a concrete road built in October and November, 1915, are reported. The concrete is of 1:1 $\frac{1}{2}$ :3 mixture and the joints were spaced 35 ft. apart. It was found that in July, 1916, 94 per cent of the joints caused no perceptible jar to traffic, 4 per cent caused a noticeable jar, and 2 per cent caused a serious jar, some being raised as much as 2 $\frac{1}{2}$  in. All joints causing a serious jar were found to be inclined from vertical. Ninety-eight per cent of the joints which heaved seriously were in sections laid later than October 15.

“It is likely that owing to the low temperature at which the concrete was laid, the unusually wet weather which prevailed during the fall of 1915, and the unusually wet and cold weather in the spring of 1916 the concrete did not set up properly. There was not the usual contraction due to the drying out of the excess water of mixing. . . . There was not sufficient space between slabs to take care of the expansion due to the increase of temperature in the early summer. . . . It would seem that, if for special reasons work must be continued late in the fall in sections with climatic conditions similar, there should be wider joints provided in the later work, as well as special precautions as to workmanship.”

General specifications for concrete bridges, W. J. WATSON (*New York: McGraw-Hill Book Co., 1916, 3. ed., pp. 70, figs. 3*).—Specifications for both municipal and rural bridges are given.

Concrete and reinforced concrete, W. L. WEBB and W. H. GIBSON (*Chicago: Amer. Tech. Soc., 1916, pp. [XI]+240, figs. 123*).—This is a condensed practical treatise on the problems of reinforced concrete designs and construction, including chapters on composition and treatment, characteristics and properties of concrete mixtures, mixing and laying concrete, waterproofing concrete, preservation of steel in concrete, fire-protective qualities of concrete, steel for reinforcing concrete, general theory of flexure in reinforced concrete, practical calculation and design of beams and slabs, T-beam construction, simple footings,

compound footings, piles, retaining walls, culverts, girder bridges, concrete building blocks, fence posts, silos, concrete walks, concrete curb, concrete construction work, and flat-slab construction.

**Calcium chlorid hastens seasoning of concrete** (*Engin. Rec.*, 74 (1916), No. 9, pp. 266, 267, figs. 3).—Tests conducted at the U. S. Bureau of Standards, under the supervision of R. J. Wig, of the 1:3 standard sand mortar showed that the rate of hardening was accelerated by the addition of calcium chlorid. It also increased the strength at 24 hours by from 155 to 230 per cent and at 48 hours by from 173 to 190 per cent over the strength of mortar containing no calcium chlorid. The best percentage of calcium chlorid to use for all proportions of concrete was from 3 to 4 per cent of the weight of the mixing water. The increase in strength at 48 hours thus obtained varied from 14 to 275 per cent for the 1:2:4 mix and from 11 to 110 per cent for the 1:1.5:3 mix. In all but one case the concretes mixed with 4 per cent of calcium chlorid showed a greater strength for both mixes than for plain concrete, these results being consistent, though variable, for all the ages tested up to 30 days. This acceleration in strength is believed to be due to the more complete hydration of the silicates and aluminates in the setting of the cement.

"The use of calcium chlorid increases the cost of concrete by 12 to 15 cts. per cubic yard. For best results it is important that the concrete be mixed to a quaking, but not fluid, consistency. Calcium chlorid should be used with caution for reinforced concrete construction, as it tends to accelerate any corrosion of the steel which may occur."

**Tensile strength of Portland cement mortars containing lime**, M. O. FULLER (*Concrete [Detroit, Mich.]*, 9 (1916), No. 3, pp. 89-91, figs. 7).—Nine series of tests of the tensile strength of Portland cement mortars with and without hydrated lime are reported. Cement paste and 1:3 mortar of both normal and working consistencies and 1:3 mortar of working consistency containing 2:5, 5, 7.5, and 10 per cent of hydrated lime were tested after storage under water, in laboratory air, outdoors exposed to the elements, in air and water, and in moist clayey soil.

It was found that "so far as specimens stored under water or in ground are concerned, the presence of lime increases the tensile strength. As compared with the above two kinds of storage . . . a storage of test specimens in dry air shows that for 21 days mortar containing no lime developed the greater strength. After 21 days the mortars containing lime showed an increase in strength, while those containing no hydrate decreased or remained nearly constant. . . . An addition of hydrated lime up to 10 per cent of the cement not only increases very considerably the plasticity of the mortar but also increases the tensile strength."

**The economical brick mortar** (*Cement and Engin. News*, 28 (1916), No. 9, pp. 192, 193).—Experiments conducted by J. S. Macgregor at Columbia University with seven different sets of nine piers, 8 by 8 by 84 in., constructed of hard-burned face bricks and common bricks bound with cement mortars of different proportions and containing varying amounts of hydrated lime, are reported, the purpose being to determine to what extent hydrated lime may replace cement in the mortar without reducing the factor of safety under practical conditions. The results are shown in the following table:

## Crushing tests of cemented brick piers.

Mixtures used—proportions by volume.			Crushed after 7 days.	Crushed after 28 days.	Crushed after 3 months.
Cement.	Sand.	Hydrated lime.	Crushing strength per square inch.	Crushing strength per square inch.	Crushing strength per square inch.
1.00	3	-----	<i>Pounds.</i> 2,630	<i>Pounds.</i> 2,840	<i>Pounds.</i> 2,840
.90	3	0.10	3,080	3,170	4,435
.85	3	.15	2,890	3,230	4,300
.75	3	.25	3,120	3,470	4,170
.50	3	.50	2,760	3,100	3,820
.25	3	.75	1,945	2,370	2,720
-----	3	1.00	1,535	1,870	1,915

"The results of this investigation unquestionably determine that hydrated lime has a greater value in brick masonry than it is generally given credit for having." "Assuming the market price of Portland cement and hydrated lime to be the same, pound for pound, specifications calling for mortar to be composed of 50 lbs. of Portland cement, 20 lbs. of hydrated lime, and 300 lbs. of sand (approximately 0.5 cu. ft. Portland cement, 0.5 cu. ft. hydrated lime, and 3 cu. ft. of sand) will not only give a much higher structural value, but will also make a saving of 30 cts. on every dollar spent for the cementing mixture in brick mortars."

Handbook of practical smithing and forging, T. MOORE (*New York: Spon & Chamberlain, 1914, pp. [VI]+248, figs. 401*).—This is a practical treatise on the arts of smithing and forging, in which the author first deals with forges, hearths, hammers, forging machines, presses, iron and steel, and testing, and then devotes considerable space to a description and discussion of practice in general forging and smithing, including a summary and explanation of technical terms, expressions, and phrases. Tables of handy data are appended.

Gas-engine principles, R. B. WHITMAN (*New York and London: D. Appleton & Co., 1915, pp. XV+248, figs. 74*).—This is a semitechnical treatise on the handling, care and maintenance of small stationary gas engines and contains the following chapters: Gas-engine principles; engine types; engine parts; valves and valve mechanism; carburetion; ignition and electrical principles; electric generators; make-and-break systems; jump spark ignition system; lubrication and cooling; power, care, and maintenance; causes of trouble; effects of trouble; and testing for trouble.

Tractor engines, W. J. McVICKER (*Gas Engine, 18 (1916), No. 7, pp. 333-336*).—In considering the requirements necessary to meet the conditions in power farming, it is pointed out that a successful tractor engine must have the following qualifications regardless of its type:

"It must be so constructed that it can develop its maximum horsepower continuously without self-destruction. The elements of limited overload must be eliminated because it can not be controlled. It must start and operate without undue loss of time and must do a season's work with ordinary care and without the services of an expert. . . . It must develop its rated power economically, and operate successfully with the kinds of fuel common in the locality where it is to be used."

A novel cooler for internal combustion engines (*Sci. Amer. Sup., 82 (1916), No. 2123, p. 165, figs. 2*).—A cooler designed for the efficient and rapid trans-

ference of heat between two fluids, one of which (air) is in the gaseous and the other in the liquid state, is described and illustrated.

"The liquid to be cooled is contained in a tank in which a number of cooling cylinders revolve. These cylinders are built of galvanized steel sheeting wound in the form of a spiral, the whole forming an enormous cooling surface in a very small space. The lower portion of the cylinders dips in the tank containing the liquid to be cooled and air is passed through the annular spaces of the upper half."

**Carburetion.** E. E. DEAN (*Gas Engine, 18 (1916), No. 7, pp. 340-343, fig. 1*).—It is pointed out in this report that in order to burn kerosene or lower grade distillates efficiently a carbureter is necessary which is capable of "delivering to the manifold, a thoroughly saturated charge, having the correct air-fuel ratio for all velocities, [and a] manifold capable of transporting this charge without change of mixture proportions and delivering it to the combustion space.

"To overcome the temperature losses due to vaporization and expansion, and assist atomization and vaporization, we must increase the temperature of the intake air. To prevent deposition of the fuel molecules, along the sides and bottom of passages, resulting in an impoverished mixture, we must apply heat to these surfaces.

"It is advisable to apply a limited amount of heat to the fuel supply to raise its temperature slightly above its vaporization point."

**Official tests of mechanical cultivation** (*Jour. Agr. Prat., n. ser., 29 (1916), No. 17, pp. 290, 291*).—Plowing tests in light soil of a 4-wheeled tractor with a 4-cylinder engine are reported. The weight of the tractor was about 6,650 kg., of which about 2,000 kg. was on the front wheels.

When plowing a furrow 15 cm. deep and 2.42 meters wide at a speed of 3,240 meters per hour, it was found that 4,902 square meters were plowed per hour with a fuel consumption per hour of 10.74 kg. and per hectare of 21.9 kg. When plowing a furrow 17.6 cm. deep and 2.4 meters wide at a speed of 3,132 meters per hour, it was found that 4,784 square meters were plowed per hour with a fuel consumption per hour of 13.2 kg. and per hectare of 27.5 kg.

**Modern piggery buildings.** H. W. POTTS and A. BROOKS (*Agr. Gaz. N. S. Wales, 27 (1916), No. 8, pp. 555-560, pl. 1, figs. 6*).—Plans and details of a building especially constructed for the housing of pedigreed stock, with board sties on one side of the passage only, are presented.

**The construction of silos.** A. M. KUIJSTEN (*Cultura, 28 (1916), No. 336, pp. 285-294, pls. 3*).—Dutch practice in silo construction is described and illustrated.

## RURAL ECONOMICS.

**The country town.** W. L. ANDERSON (*New York: Doubleday, Page & Co., 1914, pp. III+307*).—This book endeavors to set forth the rural changes in their historical, scientific, and social aspects. The author concludes that there is no scientific reason for the popular notion that the rural population is under a fatality of evil. Its future is thought to depend almost wholly upon the power of environment, education, commerce, and evangelization, and upon participation in the great movements of the age.

**The social survey: A bibliography.** compiled by Z. L. POTTER (*New York: Russell Sage Foundation, 1915, pp. 16*).—Among the topics included in this bibliography relating to rural conditions are the purpose and method of rural surveys, rural survey reports, and special reports regarding rural health and schools.

**Proceedings of the thirty-fifth annual session of the Farmers' National Congress of the United States** (*Farmers' Nat. Cong. U. S., Proc., 35 (1915), pp. 209+[4], figs. 3*).—The addresses before the congress dealt principally with

rural organizations and cooperation, rural credit, social life on the farm, and allied topics.

Value to farm families of food, fuel, and use of house, W. C. FUNK (*U. S. Dept. Agr. Bul. 410 (1916), pp. 35, figs. 3*).—The data given in this bulletin was obtained from 14 different areas in as many States and were selected as more or less typical of conditions in those States.

The results indicate that the average value of food, fuel, and use of house was \$642, of which \$424 was furnished by the farm. The average value of the food per family was \$448, and consisted of 58 per cent animal products, 25 per cent groceries, 11 per cent vegetables, and 6 per cent fruits. Of the total amount, 58 per cent was furnished by the farm. The average value of the fuel was \$62, wood comprising \$36.30, coal \$17.85, and oil \$6.33, and 54 per cent was obtained from the farm. The average value of the use of the house was \$132. The annual value of the housework was estimated at \$228, 95 per cent of which was furnished by the family.

It was found that the average value of meats (other than poultry) consumed on the farm was \$107.25, of poultry products, \$55.40, and of dairy products, \$98.36. Families living on their own farms reported a higher consumption of food and a larger proportion of food derived directly from the farm than did those living on rented farms. The cost of board (as of hired hands) in food, fuel, and housework was shown to be \$129 per year. Thirty-one per cent of this represented cash outlay.

Losses from selling cotton in the seed, C. F. CRESWELL (*U. S. Dept. Agr. Farmers' Bul. 775 (1916), pp. 8*).—The author discusses the question on the basis of interviews with farmers, ginners, oil-mill men, and others, and on the study of seed-cotton marketing previously noted (*E. S. R., 35, p. 793*). A series of tables are included, showing the prices of lint cotton, calculated from certain seed-cotton prices and certain lint percentages.

The elevator movement in the Pacific Northwest, H. T. LEWIS (*Jour. Polit. Econ., 24 (1916), No. 8, pp. 794-804*).—The author discusses the practice of shipping grain in bulk or in sacks, and the effects upon the methods of farming and grain distribution.

Report of the Bureau of Markets, 1915 (*Rpt. Bur. Markets [Newton, Mass.], 1915, pp. 56, pls. 2, figs. 10*).—This report gives a brief history of the efforts of the city of Newton, Mass., to establish a local market and the results of three months' operations.

The Federal Farm Loan Act, W. B. PALMER (*Quart. Pubs. Amer. Statis. Assoc., n. ser., 15 (1916), No. 115, pp. 292-312*).—The author gives a brief history of the circumstances leading up to the passage of this act and outlines its provisions. See also an editorial note (*E. S. R., 35, p. 101*).

The farm loan primer (*U. S. Treas. Dept., Fed. Farm Loan Bd. Circ. 5 (1916), pp. 11*).—This circular contains a series of questions which have been most frequently asked about the Federal Farm Loan Act, and answers prepared by members of the board.

National farm loan associations (*U. S. Treas. Dept., Fed. Farm Loan Bur. Circ. 1 (1916), pp. 4*).—In this circular are briefly explained the organization, management, powers, and limitations of the local loan association.

How farmers may form a national farm loan association (*U. S. Treas. Dept., Fed. Farm Loan Bur. Circ. 2 (1916), pp. 8*).—This circular indicates the various steps necessary in forming an association to borrow money under the provisions of the Farm Loan Act.

The North Carolina credit union, W. R. CAMP (*N. C. Agr. Ext. Serv. Circ. 13 (1916), pp. 11*).—This circular contains a brief statement as to the purpose of the credit union and methods of organization.

Report on the working of cooperative societies in Bihar and Orissa for the year 1914-15 (*Rpt. Work Coop. Soc. Bihar and Orissa, 1914-15, pp. 33+XVII+4*).—This report gives a brief statement of the work of the different rural credit, agricultural, and nonagricultural organizations, as well as data as to the membership, receipts, disbursements, and capital of the different societies.

The supply of agricultural implements by cooperative societies, B. C. BURT (*Agr. Jour. India, 11 (1916), No. 2, pp. 205-209, inc.*).—This article describes the experience of cooperative societies in India in purchasing implements to be rented to members of the organization.

Cattle insurance societies, A. C. CHATTERJEE (*Agr. Jour. India, 11 (1916), No. 2, pp. 108-111*).—This article contains a brief description of methods used in insuring animals purchased by loans from the agricultural primary societies in India.

Final report of the departmental committee appointed by the president of the Board of Agriculture and Fisheries to consider the settlement and employment on the land in England and Wales of discharged sailors and soldiers (*Final Rpt. Dept. Com. Land Settlement Sailors and Soldiers [London], 1916, pt. 2, pp. 39*).—This report discusses the number of men withdrawn from agriculture to join the army, and methods to be used at the close of the war to attract men into agricultural occupations. This volume contains both the majority and minority reports.

Farming and food supplies in time of war, R. H. REW (*Rpt. Brit. Assoc. Adv. Sci., 85 (1915), pp. 760-769*).—The author discusses the influence of home production and the relative proportion of the different products obtained by importation, also the changes which have taken place under war conditions.

Our food supply, C. TURNOR (*London and New York: C. Scribner's Sons, 1916, pp. IX+171*).—The author discusses the food supply in England and subjects relating thereto under the following heads: Present and suggested sources of food supply; present agricultural methods; new and improved methods; the laborer; small holdings; land settlement for ex-service men; education; and agricultural credit.

[Report of the German food supplies committee] (*Better Business, 1 (1915), No. 1, pp. 51-70*).—This article describes the functions of the committee in dealing with the production and distribution of agricultural products under war conditions.

Vacant public lands on July 1, 1915, and July 1, 1916 (*U. S. Dept. Int., Gen. Land Off. Circs. 420 (1915), pp. 24; 484 (1916), pp. 24*).—These reports continue the information previously noted (*E. S. R., 32, p. 390*) and correct the data up to July 1, 1916.

Circular instructions relating to acquisition of title to public lands in the Territory of Alaska, compiled by C. TALLMAN (*U. S. Dept. Int., Gen. Land Off. Circ. 491 (1916), pp. 89*).—This circular contains a compilation of laws and regulations governing the acquisition of title to public lands in Alaska.

Vermont farms (*Essex Junction, Vt.: Vt. Bur. Pub. [1915], pp. 140, figs. 16*).—This report contains a detailed statement of facts and figures concerning the agricultural resources and opportunities of the State.

Twenty-first biennial report of the Bureau of Agriculture, Labor, and Statistics of Kentucky (*Bien. Rpt. Bur. Agr., Labor, and Statis. Ky., 21 (1914-15), pp. 530, pls. 32*).—This report contains a statement showing for each county in the State the population, assessed acreage, value of land and improvement, and a brief description of agricultural land and the type of agriculture practiced, and outlines the activities of the various branches of the bureau.

[**Agriculture in Hawaii**], (*Rpt. Gov. Hawaii, 1914, pp. 9-12, 26-30, 39-42, 47-51, 53-57*).—The subjects treated are the land problem, transportation, land settlement, the work of the Bureau of Agriculture and Fisheries, and agricultural education.

**Grain statistics of Canada, 1914-15**, R. MAGILL, W. D. STAPLES, and J. P. JONES (*Canada Ann. Rpt. Dept. Trade and Com., pt. 5 (1916), pp. VII+320, pls. 5*).—In this report is contained the report of the grain commissioners showing the amount of grain handled by the various Canadian elevators, daily, monthly, and yearly prices, and the activities of the different branches of the board in connection with the licensing of elevators and the inspection of the grain and elevators.

[**Agricultural statistics of São Paulo**] (*Bol. Dir. Indus. e Com. São Paulo, 7. ser., No. 6 (1916), pp. 235-278*).—This report gives data showing the area, production, and trade of the principal agricultural products.

**Production and trade in agricultural products of Great Britain and Ireland, 1915**, J. J. L. VAN RIJN (*Dept. Landb., Nijv. en Handel [Netherlands], Verslag. en Meded. Dir. Landb., No. 1 (1916), pp. 106-157, figs. 3*).—In this report is discussed the relative importance of the home production and the imported agricultural products, and the sources of agricultural imports and prices.

**Fourth report of the board of agriculture for Scotland**, R. P. WRIGHT ET AL. (*Rpt. Bd. Agr. Scot. 4 (1915), pp. 59*).—In this report is reviewed the work of the board during the past year. It treats principally of the progress in land settlement, agricultural education and research, and the agricultural problems due to the war.

[**Agricultural production in Austria, 1915**] (*Anbauflächen und Ernteergebnisse in Österreich im Jahre 1915. Vienna: K. K. Ackerbauministerium 1916, pp. 55*).—This report gives the area, production, and average yield of the principal crops in Austria and by minor subdivisions for 1915, with comparative data for earlier years.

**The recent development of German agriculture**, T. H. MIDDLETON (*Abs. in Jour. Bd. Agr. [London], 23 (1916), No. 5, pp. 426-430*).—In this article is given a synopsis comparing the efficiency of agricultural methods in England and Germany, and pointing out the differences in the results obtained.

**Agricultural statistics of British India, 1913-14**, G. F. SHIRRAS (*Agr. Statis. India, 30 (1913-14), I, pp. X+415, pls. 5*).—This report continues the information previously noted (*E. S. R., 34, p. 92*) by adding data for the crop year of 1913-14.

## AGRICULTURAL EDUCATION.

**Agricultural and industrial education, consolidation of schools, training and supply of teachers, courses of study, physical and moral education, with recommendations** (*Rpt. Saskatchewan Ed. Com., 1915, pp. 208*).—Part one of this report of the Saskatchewan Educational Commission, which was appointed May 9, 1912, contains (1) a report on the present status of agricultural education in Saskatchewan; accounts of what is being done in agricultural instruction in Alberta, Manitoba, Ontario, Michigan, Massachusetts, Wisconsin, England, Scotland, France, and Belgium, including a summary of legislation in eight States; and descriptions of typical agricultural schools in the United States and Australia; and (2) a similar account of the present status of industrial education, including instruction in home economics. A bibliography on agricultural and industrial education, etc., is among the data appended.

The commission recommends that in Saskatchewan agricultural and industrial education be amplified and extended by the use of existing agencies, viz, the public, high, and normal schools, and the university, including the agricultural college. It advocates (1) systematic efforts to introduce nature study, school gardening, manual training, and elementary household science more generally into the public schools and to provide in the more advanced schools instruction and training for the preparation of teachers and leaders in these departments; (2) short courses in agriculture and elementary science during vacation periods, where necessary, to be given in rural schools by traveling expert instructors; (3) the establishment of industrial evening schools in villages and towns; (4) provision in high schools for short winter courses in agriculture and instruction in advanced manual training and household science and such specialized form of industrial work as may be deemed advisable; (5) initial and annual grants and expert direction for work in public and high schools in school gardening and agriculture, household science, manual training, and related branches; (6) increased facilities for instruction in school gardening and elementary agriculture, manual training, and elementary household science in the provincial normal schools; (7) the establishment in the university of a school of domestic science and a college of technology for a corresponding development of industrial education; (8) the acceptance of either agriculture or household science in lieu of physics or chemistry in the examinations for third and second class teachers' diplomas and in the university at the junior matriculation examination; and (9) the appointment of expert district representatives to assist the department and college of agriculture in promoting the welfare of rural communities.

Part two deals with the supply and training of teachers, courses of study, textbooks in Saskatchewan, and the consolidation of schools in the United States.

**Agricultural education in New South Wales, T. E. SEDGWICK** (*Jour. Bath and West and South Counties Soc.*, 5. ser., 10 (1915-16), pp. 77-86).—An account is given of the system of agricultural instruction in New South Wales, which affords an uninterrupted opportunity for students to pass successively through the primary school, the Hurlstone Agricultural High School, the experimental farm and school, the Hawkesbury Agricultural College, and the university, where the degree of B. S. in Agriculture is awarded, thus qualifying for a Government inspectorship or other appointment.

**Agricultural education in the State of Victoria, Australia, C. K. HARRISON** (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1154-1156).—This is a summarized statement of agricultural teaching in the primary state schools, technical schools, agricultural colleges and experimental farms, and extension teaching.

**Gardening and farming in the Philippine schools, N. H. FOREMAN** (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1156-1159).—The following phases of agricultural instruction in the Philippine schools are briefly described: School gardening, special food campaigns, settlement farm schools, farm schools, and agricultural schools.

The development of the Philippine public-school system in cooperation with the home and in relation to industrial conditions, H. H. MILLER (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1116-1121).—The growth of the system, the courses of study and their aim, including school gardening, farming, housekeeping, and household arts, and how the homes are reached, are discussed.

**Rural science and school gardening, W. H. JOHNS** (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 16 (1916), No. 3, pp. 441-454, pls. 4).—The author dis-

discusses the reasons for adopting instruction in school gardening in public elementary and other schools in Ireland, the correlation of school gardening with other subjects, the training of teachers of school gardening, schemes of instruction, the plan of a typical garden, managing and cropping gardens, site and equipment, operations, etc. The syllabus in rural science, including school gardening, for the training of national school teachers at the Royal College of Science for Ireland, Dublin, and in classes at approved centers in a few selected counties is given.

The author states that "perhaps the main distinction between the various British and Irish schemes of school gardening lies in the fact that in Great Britain the subject is regarded mainly as a practical or handicraft subject, whereas in Ireland the Department [of Agriculture and Technical Instruction], while insisting upon the practical side, has sought to coordinate it with the teaching of elementary practical science with the view to making it truly educational." The general beginning of school garden work in Ireland dates from 1910, when the department's present scheme of rural science and school gardening was introduced. At present there are 150 schools in which the subject is taught by specially trained teachers. The schemes of instruction for the training of both teachers and pupils in national schools are very similar, and the subject may be said to center around the life study of a typical garden plant. Teachers of this subject in Ireland may earn small special grants as well as prizes.

**High-school extension in agriculture, C. H. LANE** (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1132-1136).—The author includes under high school extension work in agriculture "all educational efforts at the homes and on the farms of the people, and also such work at the school itself as is more or less temporary and that centers directly in interests away from the school." He discusses when and how such work should be undertaken by high schools and the training of teachers for extension work.

Courses for training teachers should contain two essential elements, viz, sound training in the science of agriculture and sound experience in the practice of the art. It is deemed extremely doubtful whether the student training to become a high-school instructor in agricultural extension work "should be permitted to specialize in the latter part of a course as is now common in larger institutions. On the contrary, since he is to be a teacher, it is necessary for him to have training in psychology and in the principles and methods of education." He should give careful attention to language work and have much practice in the clear and simple statement of his thoughts and in public speaking, and inasmuch as he is to promote successfully farm practice, stress should be laid on instruction in farm management, rural economies, and rural sociology. Provision should also be made for actual practice in extension work in the junior and senior years.

The ways suggested for the teacher of agriculture to extend his influence outside of his regular high-school work include the supervision of the home-project work of his pupils, the directing of agricultural instruction in the grades, the organizing and following up of boys' and girls' clubs, the acting as organizer for the one week's short course for farmers, the offering of personal counsel and advice on certain days to farmers of the community, assisting in organizing farmers' reading courses, directing school agricultural exhibits locally and at the county fair, and through Saturday meetings with farmers and by farm visitation.

**School credit for boys' and girls' club work and extension activities in agriculture and home economics, O. H. BENSON** (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1144-1153).—The author discusses boys' and girls' club

work as it is related to the public school and its claim upon the school from the standpoint of school credit. While he considers "the education, experience, health, and conservation value, together with the blessings of the out of doors and a net profit on investment," the best possible credit that may be received from club work, so far as the boys and girls are concerned, he believes it will be worth while for the school to express itself in a tangible way in connection with this work for the benefit of the school and the school curriculum. It is recommended that all of the bases of awards used in club home projects be also used as the bases of awards for the giving of school credits. A list of projects, specific requirements, and standards for awarding school credit for each project are given.

**How boys and girls respond to home work in a large city.** C. F. PALMER (*Addresses and Proc. Nat. Ed. Assoc.*, 53 (1915), pp. 1139-1143).—An account is given of home gardening in Los Angeles and its good effects.

**Girls' and boys' club work: A manual for rural teachers,** MARY E. CRESWELL (*Bul. Ga. State Col. Agr.*, No. 101 (1916), pp. 52, figs. 5).—In this bulletin the following subjects are discussed: School Values in Boys' and Girls' Club Work, by H. W. Odum; Relating Boys' and Girls' Club Work with that of the Public Schools and Seasonal Activities, by Mrs. Bessie S. Wood; Correlation of Agriculture and Home Economics with Common-school Subjects in Georgia, and Arithmetic Problems Based on Germination of Seed Corn, by Miss C. S. Parrish; Purpose of Boys' Corn Clubs, by J. K. Giles; Boys' and Girls' Poultry Clubs, by D. J. Taylor; Boys' Pig Clubs in Georgia, by J. E. Downing; Some Typical Programs for Meetings, by Miss Nola Johnson; and Historical Development, Keeping Records, Lessons Connected with Canning, etc., by the author. A brief list of references is included.

### MISCELLANEOUS.

**Twenty-second Annual Report of Montana Station, 1915** (*Montana Sta. Rpt. 1915*, pp. 221-263).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1915, and a report of the director on the work and publications of the station. The experimental work reported is for the most part abstracted elsewhere in this issue.

**Twenty-eighth Annual Report of Vermont Station, 1915** (*Vermont Sta. Rpt. 1915*, pp. XXIII+462+4, pls. 32, figs. 105).—This contains the organization list, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1915, a report of the director on the publications and work of the station, and reprints of Bulletins 184-190, previously noted, and of Circular 9, noted below.

**Publications for free distribution** (*Vermont Sta. Circ. 9* (1915), pp. 4).—The publications available for distribution are listed.

**List of available publications** (*West Virginia Sta. Circ. 23* (1916), pp. 4).—The station bulletins and circulars and the extension department publications available for distribution are listed.

## NOTES.

---

**Hawaii College.**—Jared G. Smith, professor of agriculture, has resigned to become manager for a large commercial tobacco growing company on the island of Oahu, and has been succeeded by L. A. Henke, previously director of agriculture at the high school of Elbow Lake, Minnesota.

**Maryland College and Station.**—Dr. A. F. Woods, dean of the Minnesota College and School of Agriculture and director of the Minnesota Station, has been appointed president of the college beginning July 1. Dr. H. J. Patterson, the retiring president, will continue as director of the station. Dr. Raymond C. Reed, professor of bacteriology, hygiene, and veterinary science at the Delaware College and animal pathologist of the Delaware Station, has been appointed chief of the department of animal industry.

Capt. Richard W. Silvester, president of the college from 1892 to 1913 and subsequently president emeritus and librarian, died December 31, 1916, at the age of 59 years.

**Massachusetts College and Station.**—Additional appropriations aggregating \$488,200 have been requested from the State Legislature. Of this amount \$250,000 is for a library building, \$90,000 for extensions to the power plant, \$85,000 for other equipment and improvements, \$50,000 for a dormitory, \$9,000 for rural engineering shops, and \$4,200 for a poultry house and judging laboratory. In addition \$35,000 is requested to improve, equip for experimental work, and maintain for two years the tract of land acquired at Lexington, under a previous appropriation of \$8,000, for use as a market garden field station under the management of the college.

A. B. Beaumont, assistant professor of soil technology in Cornell University, has been appointed associate professor of agronomy and acting head of the department. E. D. Waid, assistant director of the extension service, has resigned to engage in farming. In the station Dr. A. C. Edwards, assistant in veterinary science, resigned December 31, 1916. S. H. DeVault has been appointed graduate assistant in agricultural economics.

**New Hampshire College.**—Pres. E. T. Fairchild died at Durham, N. H., January 23, at the age of 62 years. President Fairchild was a native of Ohio, for 10 years a regent of the Kansas College, and from 1907 to 1912 State superintendent of public instruction in Kansas. He had been president of the New Hampshire College since 1912, during which time the enrollment and equipment of the institution had been largely increased. He was widely known in educational circles, and served as president of the National Education Association in 1912.

**North Carolina College and Station.**—Some interesting results are reported by the division of horticulture from work with pecans in the eastern part of the State. A large part of the old trees have been renewed by top-working, etc., with varieties such as Stuart and Schley, which have been found to be the best adapted for the purpose.

B. P. Folk, State agent in charge of pig club work, resigned January 1 to engage in farming in Louisiana. In the division of agricultural clubs A. K.

Robertson, assistant in corn club work, has been promoted to agent in corn club work.

**South Carolina Station.**—The division of entomology has completed an elaborate apparatus for the control of temperature and moisture. The principle consists of pumping air through an ice chamber and expanding it by heat in a second chamber to acquire the desired humidity. The temperature of individual insects is recorded by means of an electric thermocouple.

The division has also completed its field laboratory for entomological study. This building is equipped with the necessary thermographs for air and soil temperatures and other apparatus.

**Vermont University and Station.**—A. F. Hawes, professor of forestry and State forester, has resigned to take effect February 15, to become extension specialist in forestry in the Office of Extension Work in the North and West of the States Relations Service of the U. S. Department of Agriculture. W. C. Stone, assistant horticulturist in the station, has accepted a similar appointment in the New York State Station, and has been succeeded by John B. Norton, a 1914 graduate of the Massachusetts College.

**Washington College.**—The State legislature of 1915 appointed an educational commission of three senators and three representatives to make a survey of the educational situation in the State, and specifically of the State college, the State university, and the three normal schools. This commission subsequently secured the services of the United States Bureau of Education in making a survey, the results of which were recently published. The recommendations in this report were embodied in a bill presented to the legislature, in which provision was made for the transference of several departments and all graduate work in engineering and pure science from the college to the university.

This measure failed of passage, and in its stead a law was enacted defining the fields of work of the two institutions. This law provides that the courses of instruction at the university shall embrace, as exclusive major lines, law, architecture, forestry, commerce, journalism, library economy, marine and aeronautic engineering, and fisheries, as well as instruction in medicine. Those of the State college are to embrace, as exclusive major lines, agriculture in all its branches and subdivisions, veterinary medicine, and economic science in its applications to agriculture and rural life. Both the university and the State college are to offer as major lines courses in the liberal arts, pure science, pharmacy, mining, civil engineering, electrical engineering, mechanical engineering, chemical engineering, home economics, and the professional training of high school teachers, school supervisors, and school superintendents.

The law further provides for a joint board of higher curricula of nine members chosen from the presidents and regents of the five State institutions of higher learning. In the future all major lines of work taken up by any of these institutions must first be approved by a two-thirds vote of this board.

A second act was passed granting in perpetuity to the State college all Federal land hitherto allotted to the State for a scientific school, and also definitely allotting to the same institution all Federal funds granted under the Morrill Act and all legislation supplementary thereto.

**States Relations Service.**—Dr. E. V. Wilcox, administrative assistant in the Office of Experiment Stations, has been transferred to the Office of Farm Management of the U. S. Department of Agriculture, where he is to carry on studies of systems of land tenure, and has entered upon his duties.

**Dominion Experimental Farms.**—Tracts of timber land are being cleared and prepared, mainly through the labor of interned aliens, at Kapuskasing in northern Ontario and Spirit Lake in northern Quebec for eventual use as sub-

stations. The site in Ontario comprises about 1,000 acres in the township of O'Brien, where a considerable area has been cleared, drainage begun, and about 125 acres of field crops grown. A horse barn has been nearly completed and a cattle barn is under way.

The Quebec tract is situated in the townships of Trecesson and Dalquier, and is expected to comprise about 1,600 acres. Not all of this tract is arable, but about 150 acres of field crops have already been grown. Considerable clearing and draining have been done and a small greenhouse has been erected. Smith Ballantyne has been appointed foreman manager at Kapuskasing and Pascal Fortier at Spirit Lake. Considerable difficulty is reported in getting the prisoners to work, and it is not expected to carry on much experimental work under the present conditions. It is, however, hoped to accomplish a good deal in the preparatory operations of clearing, breaking, and draining the land, and thus have as much as possible ready when experiments can be begun.

**Society for the Promotion of Agricultural Science.**—The thirty-seventh annual meeting of this society was held at Washington, D. C., November 13 and 14, 1916.

The presidential address was given by Director C. E. Thorne of Ohio, at a joint session of the society with the American Farm Management Association and the American Society of Agronomy. In this paper Director Thorne reviewed the history and development of the society and discussed its opportunities for future service. As among these, he suggested the desirability of considering the federating of the various organizations of workers in agricultural science. This proposition subsequently received considerable discussion at the business meeting of the society, at which a plan of reorganization was submitted by Director C. D. Woods of Maine. A poll of the entire membership of the society was eventually decided upon.

The papers read and discussed were as follows: Improving Grasses by Selections, by W. J. Beal; The Mineral Metabolism of the Milch Cow, by E. B. Forbes; Agricultural Grasses, by C. V. Piper; Boys' and Girls' Club Work in Relation to Agricultural Education, by W. D. Hurd; The Physiological Requirements of Wheat and Soy Beans Growing in Sand Media, by A. G. McCall; The Factors Determining Quality in Milling Wheats, by J. S. Jones; Observations on Meadow Insects, by Herbert Osborn; Varying Effects of Salt on Different Plant Families, by S. M. Tracy; Forest Depredations and Utilization, by F. W. Rane; The Straw Mulch in Orchard Management, by C. B. Lipman; and The Farmer's Knowledge of the Details of his Business, by W. J. Spillman.

The election of officers for the ensuing year resulted as follows: President, Herbert Osborn; vice-president, W. P. Brooks; secretary-treasurer, C. P. Gillette; custodian, W. D. Hurd; and member of the executive committee, W. R. Dodson.

**American Farm Management Association.**—The seventh annual meeting of this association was held at Washington, D. C., November 13 and 14, 1916.

In the absence of the president, Director H. A. Morgan of Tennessee, the annual address was given by the vice-president, H. W. Jeffers of Plainsbury, N. J., upon the subject of How the Investigator of Farm Management Problems Can Help the Farmer. Mr. Jeffers drew attention to the changing conditions of modern life, and stated that despite the advancement in the technique of agriculture, this calling has been among the slowest to respond to modern methods as regards efficiency. Farmers, however, are beginning to analyze their business, and from this standpoint need assistance especially in bringing about the standardization of the farm organization and the farm enter-

prise. Regional studies of farm practice and studies of the efficient use of farm machinery were also cited as desirable.

Assistant Secretary of Agriculture Vrooman addressed the association, expressing his special interest in the kind of work which it represented. He pointed out that if there is to be a permanent agriculture, farm operations must be made profitable and that farming, which too often has been merely an occupation, must become a business. The individual farmer, in his view, ought no more to be expected to be an expert in farm management than in chemistry, plant diseases, or the like, but should receive the benefits of those trained to correlate the many complex factors with which he is called upon to deal.

The program also included the following papers: Farm Management Extension, by S. B. Cleland and E. A. Brown; The Farmer as a Social Institution, by E. A. Goldenweiser; Climatic Factors in Relation to Farm Management Practice, by J. Warren Smith; Relation of Agronomy to Farm Management, by C. V. Piper; The Poor Man on Poor Land, by J. S. Cates; Adequate and Economic Farm Buildings, by J. H. Hankinson; Consideration of a Simple Method of Determining the Relative Profitableness of Different Farm Enterprises, by D. H. Otis and R. V. Gunn; Cost Accounting on Farms, by G. F. Warren; and Farm Management Problems in Horticulture, by L. C. Corbett.

Reports were received from several committees of the association. The report on farm management investigations, R. L. Adams, chairman, summarized the work under way in the U. S. Department of Agriculture and the agricultural colleges and experiment stations. No work was reported from sixteen institutions, but that of the remainder showed a considerable scope and variety. The report of the committee on extension work, L. H. Goddard, chairman, dealt especially with the collection of farm analysis records and the relations to be observed with the county agents and farm bureaus in carrying on work of this sort. The status of farm management teaching was reviewed in the report of the committee on that subject, of which O. R. Johnson was chairman.

Definitions for the terms "farm management," "animal unit," "family labor," "labor income," "family labor income," "family income," "paid labor," "crop index," "dairy farm," "general farm," "man work unit," and "horse work unit" were proposed by the committee on standardization of nomenclature. These definitions were tentatively adopted by the association, final action being deferred until the next meeting.

An amendment to the constitution providing a third standing committee on farm management extension was adopted. The executive committee was instructed to confer with representatives of other societies with reference to the joint publication of a journal.

Officers for the ensuing year were elected as follows: President, H. W. Jeffers; vice-president, F. W. Peck; and secretary-treasurer, G. A. Billings.

**Association of Official Agricultural Chemists.**—The thirty-third annual convention of the association was held November 20–22, 1916, at Washington, D. C., with a registration somewhat larger than that of the previous year. Assistant Secretary of Agriculture Vrooman welcomed the members of the association to Washington, and pointed out the important relation existing between the chemist and the people, and also the dependence of the people on the accurate, definite scientific knowledge developed by the chemist.

The annual address of the president of the association, Dr. R. N. Brackett, reviewed the history of the association from its beginning. He traced its influence on the development of other chemical organizations and activities, the establishment of food and drug standards, and the development of methods for the control of various products, related either directly or indirectly to

agriculture, and drew attention to the many opportunities for constructive work still available.

The honorary president, Dr. H. W. Wiley, also addressed the convention and spoke of the development of various branches of chemistry which he had been privileged to observe. He pointed out the dependence of the public health and welfare on the work of the chemist, and maintained that the important service rendered justified adequate recognition by the people.

The usual reports of the referees and associate referees were read and discussed, and, following reports from the committees on recommendations of referees, were accepted. It is expected that these reports will be published in full in the *Journal* of the association at an early date.

Dr. C. B. Lipman pointed out that many methods at present used for soil analysis are of little value, while there are many methods used by soil chemists throughout the country which yield excellent results but are not considered official. He emphasized the necessity of gathering, studying, and revising these various methods so as to produce, if possible, a uniform set of accurate procedures for soil analysis. A special soil analysis committee composed of the referee (Dr. Lipman), the associate referee (W. H. McIntire), and E. C. Shorey, A. W. Blair, and Robert Stewart, was appointed to consider these matters.

A committee was also appointed to study and consider the subject of the sampling of fertilizers, to cooperate with a like committee from the fertilizer section of the American Chemical Society. This committee consists of C. H. Jones, W. J. Jones, jr., and B. F. Robertson.

The report of the committee on editing methods of analysis was accepted, and the committee continued and authorized to incorporate such further changes in the methods as have been or might be recommended by the association. The committee expressed the hope that it would soon be able to publish the newly revised methods in compact and convenient form.

A recommendation from the executive committee for a new classification of subjects for the referees and associate referees was accepted. The new classification is considered more uniform and consistent than its predecessor. Several minor changes were also made in the constitution and by-laws.

The secretary reported that the *Journal* of the association had removed its financial deficit, and that its permanency seemed established. The number of foreign subscriptions was deemed especially gratifying, indicating the widespread appreciation of the value of the publication. A vacancy on the board of editors, caused by the expiration of the term of Dr. L. L. Van Slyke, was filled by his reappointment.

The following special papers were read at the meeting: The Inosit Phosphoric Acid of Cotton-Seed Meal, by J. B. Rather; The Titration of Grain Extracts in the Presence of Alcohol, and A Simple Method for Measuring the Acidity of Cereal Products and Its Application to Sulphured and Unsulphured Oats, by V. Birckner; Origin of the Neutralization Precipitate of Cow's Milk, by L. S. Palmer; The Separation and Gravimetric Estimation of Potassium, by S. B. Kuzirian; A New Rapid and Accurate Method for Estimating Lime and Potash in Soils, by T. E. Keitt and C. J. King; The Occurrence and Determination of As<sup>v</sup> and As<sup>iii</sup> in the Presence of Each Other in Arsenical Insecticides, by R. C. Roark; The Relation of the Lime Requirement of Soils to Their Retention of Ammonia, by L. P. Howard; Titration of the Acidity of Colored Solutions, by B. G. Hartmann; A Note on the Calculation of the Volume of a Liquid from Weight and Specific Gravity, and The Volatile Reducing Substances in Cider Vinegar, by R. W. Balcom; The Isolation and Identification of Glycerin in

Cider Vinegar, by R. W. Balcom and E. G. Grab; Tartrazin, by Miss A. M. Doyle; C. R. Smith's Method for the Determination of Arsenic, by W. D. Collins; and The Manufacture of Benzaldehyde and Benzoic Acid as a By-Product using Ultraviolet Rays as a Catalyst, by H. D. Gibbs and G. A. Geiger.

Resolutions were adopted on the death during the year of the following members: Prof. Robert James Davidson, of the Virginia Polytechnic Institute; Dr. George Edward Patrick, chief of the Dairy Laboratory of the Bureau of Chemistry; and Thomas Cuthbert Trescot, also of the Bureau of Chemistry.

The following officers were elected for the coming year: J. K. Haywood, Washington, D. C., president; P. F. Trowbridge, Columbia, Mo., vice-president; Carl L. Alsberg, Washington, D. C., secretary and treasurer; and B. B. Ross, Auburn, Ala., and H. C. Lythgoe, Boston, Mass., members of the executive committee. It was decided to hold the next meeting at Washington, D. C., the date to be decided by the executive committee.

**Necrology.**—Dr. N. H. J. Miller, connected with the Rothamsted Station since 1887, died January 12. His chief work during his long service was the measurement of the amount of combined nitrogen brought down in the rain and the amount of nitric nitrogen washed out from the snow. For over 30 years he had analyzed a sample of every collection of rain from a large rain gauge at the station, obtaining a continuous set of observations of extreme scientific value.

Dr. Miller was also much interested in the literature of agricultural chemistry. For many years he did nearly all the abstracting in chemistry for the British Chemical Society, and in recent years had prepared the society's annual review of progress in that subject.

Marquis de Vogué, president of the Agricultural Society of France, died in November, 1916, at the age of 87 years. Although he was also a diplomatist, a historian, a musician, an architect, and a painter, he was much interested in agricultural chemistry, and installed a laboratory at his chateau at Peseau, where he carried on experiments in the use of fertilizers for potatoes, the use of basic slag, nitrification and the loss of nitrates from lands left uncultivated after harvest, and the effect of the ammoniacal liquor from gas works on the straw of cereals. As president of the society he exerted a considerable influence to improve agricultural conditions in France, especially along economic lines.

**Miscellaneous.**—Arthur H. Rosenfeld, director of the experiment station at Tucuman, Argentina, since 1914, has resigned and has been succeeded by Dr. W. E. Cross, for several months acting director. Dr. Cross will also continue as head of the department of chemistry, while E. W. Rust has been given charge of the work in entomology. P. V. Janutolo has been appointed assistant in chemistry.

The Cheshire Educational Committee has voted to close the County Council's Agricultural and Horticultural College at Holmes Chapel, England, but a resolution has also been passed asking the Board of Agriculture and Fisheries to take over the institution during the war, with a view to training disabled sailors and soldiers in farm and garden work.

A new feed control station was opened at Wageningen, Holland, November 28, 1916, with Dr. B. R. de Bruyn as director.

WEATHER BUREAU—C. F. Marvin, *Chief*.  
 BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.  
 BUREAU OF PLANT INDUSTRY—W. A. Taylor, *Chief*.  
 FOREST SERVICE—H. S. Graves, *Forester*.  
 BUREAU OF SOILS—Milton Whitney, *Chief*.  
 BUREAU OF CHEMISTRY—C. L. Alsberg, *Chief*.  
 BUREAU OF CROP ESTIMATES—L. M. Estabrook, *Statistician*.  
 BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.  
 BUREAU OF BIOLOGICAL SURVEY—E. W. Nelson, *Chief*.  
 OFFICE OF PUBLIC ROADS AND RURAL ENGINEERING—L. W. Page, *Director*.  
 OFFICE OF MARKETS AND RURAL ORGANIZATION—C. J. Brand, *Chief*.

STATES RELATIONS SERVICE—A. C. True, *Director*.  
 OFFICE OF EXPERIMENT STATIONS—E. W. Allen, *Chief*.

## THE AGRICULTURAL EXPERIMENT STATIONS.

### ALABAMA—

College Station: *Auburn*; J. F. Duggar.<sup>1</sup>  
 Canebrake Station: *Uniontown*; L. H. Moore.<sup>1</sup>  
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.<sup>1</sup>

ALASKA—*Sitka*: C. C. Georgeson.<sup>2</sup>

ARIZONA—*Tucson*: R. H. Forbes.<sup>1</sup>

ARKANSAS—*Fayetteville*: M. Nelson.<sup>1</sup>

CALIFORNIA—*Berkeley*: T. F. Hunt.<sup>1</sup>

COLORADO—*Fort Collins*: C. P. Gillette.<sup>1</sup>

### CONNECTICUT—

State Station: *New Haven*; } E. H. Jenkins.<sup>1</sup>  
 Storrs Station: *Storrs*; }

DELAWARE—*Newark*: H. Hayward.<sup>1</sup>

FLORIDA—*Gainesville*: P. H. Rolfs.<sup>1</sup>

GEORGIA—*Experiment*: J. D. Price.<sup>1</sup>

GUAM—*Island of Guam*: C. W. Edwards.<sup>1</sup>

### HAWAII—

Federal Station: *Honolulu*; J. M. Westgate.<sup>2</sup>  
 Sugar Planters' Station: *Honolulu*; H. P. Agee.<sup>1</sup>

IDAHO—*Moscow*: J. S. Jones.<sup>1</sup>

ILLINOIS—*Urbana*: E. Davenport.<sup>1</sup>

INDIANA—*La Fayette*: A. Goss.<sup>1</sup>

IOWA—*Ames*: C. F. Curtiss.<sup>1</sup>

KANSAS—*Manhattan*: W. M. Jardine.<sup>1</sup>

KENTUCKY—*Lexington*: A. M. Peter.<sup>4</sup>

### LOUISIANA—

State Station: *Baton Rouge*; }  
 Sugar Station: *Audubon Park*, } W. R. Dodson.<sup>1</sup>  
*New Orleans*; }  
 North La. Station: *Calhoun*; }

MAINE—*Orono*: C. D. Woods.<sup>1</sup>

MARYLAND—*College Park*: H. J. Patterson.<sup>1</sup>

MASSACHUSETTS—*Amherst*: W. P. Brooks.<sup>1</sup>

MICHIGAN—*East Lansing*: R. S. Shaw.<sup>1</sup>

MINNESOTA—*University Farm, St. Paul*: A. F. Woods.<sup>1</sup>

MISSISSIPPI—*Agricultural College*: E. R. Lloyd.<sup>1</sup>

### MISSOURI—

College Station: *Columbia*; F. B. Mumford.<sup>1</sup>  
 Fruit Station: *Mountain Grove*; Paul Evans.<sup>1</sup>

MONTANA—*Bozeman*: F. B. Linfield.<sup>1</sup>

NEBRASKA—*Lincoln*: E. A. Burnett.<sup>1</sup>

NEVADA—*Reno*: S. B. Doten.<sup>1</sup>

NEW HAMPSHIRE—*Durham*: J. C. Kendall.<sup>1</sup>

NEW JERSEY—*New Brunswick*: J. G. Lipman.<sup>1</sup>

NEW MEXICO—*State College*: Fabian Garcia.<sup>1</sup>

### NEW YORK—

State Station: *Geneva*; W. H. Jordan.<sup>1</sup>

Cornell Station: *Ithaca*; A. R. Mann.<sup>4</sup>

### NORTH CAROLINA—

College Station: *West Raleigh*; } B. W. Kilgore.<sup>1</sup>  
 State Station: *Raleigh*; }

NORTH DAKOTA—*Agricultural College*: T. P. Cooper.<sup>1</sup>

OHIO—*Wooster*: C. E. Thorne.<sup>1</sup>

OKLAHOMA—*Stillwater*: W. L. Carlyle.<sup>1</sup>

OREGON—*Corvallis*: A. B. Cordley.<sup>1</sup>

### PENNSYLVANIA—

State College: R. L. Watts.<sup>1</sup>

State College: *Institute of Animal Nutrition*; H. P. Armsby.<sup>1</sup>

### PORTO RICO—

Federal Station: *Mayaguez*; D. W. May.<sup>2</sup>

Insular Station: *Rio Piedras*; W. V. Tower.<sup>1</sup>

RHODE ISLAND—*Kingston*: B. L. Hartwell.<sup>1</sup>

SOUTH CAROLINA—*Clemson College*: C. C. Newman.<sup>4</sup>

SOUTH DAKOTA—*Brookings*: J. W. Wilson.<sup>1</sup>

TENNESSEE—*Knoxville*: H. A. Morgan.<sup>1</sup>

TEXAS—*College Station*: B. Youngblood.<sup>1</sup>

UTAH—*Logan*: F. S. Harris.<sup>1</sup>

VERMONT—*Burlington*: J. L. Hills.

### VIRGINIA—

*Blacksburg*: A. W. Drinkard, jr.<sup>1</sup>

*Norfolk*: Truck Station; T. C. Johnson.<sup>1</sup>

WASHINGTON—*Pullman*: I. D. Cardiff.<sup>1</sup>

WEST VIRGINIA—*Morgantown*: J. L. Coulter.<sup>1</sup>

WISCONSIN—*Madison*: H. L. Russell.<sup>1</sup>

WYOMING—*Laramie*: H. G. Knight.<sup>1</sup>

<sup>1</sup> Director. <sup>2</sup> Agronomist in charge. <sup>3</sup> Animal husbandman in charge. <sup>4</sup> Acting director.

	Page.
A comparison of barbituric acid, thiobarbituric acid, and malonylguanidin as quantitative precipitants for furfural; Dox and Plaisance.....	318
Methods in soil analysis, Bear and Salter.....	318
Estimation of thiosulphate sulphur in lime-sulphur, Blumenthal and Averitt..	318
[Report of the chemical division], Wright.....	319
The conservation of fruits and vegetables by desiccation, Valvassori.....	319
Instructions for processing fruits and vegetables for exhibition only, Page....	319
Report on vegetable dyestuffs, Marsden.....	319

## SOILS—FERTILIZERS.

Measurement of the surface forces in soils, Shull.....	319
Indirect methods for hygroscopic coefficients of soils, Alway and Clark.....	320
Note on soil denudation by rainfall and drainage, Hope.....	320
Soil aeration in agriculture, Howard.....	320
The toxicity of bog water, Rigg.....	320
Some factors influencing nitrogen fixation and nitrification, Williams.....	321
Production of alkali in soils by denitrification, Aladjem.....	321
Further observations on protozoa in relation to soil bacteria, Goodey.....	322
Soils of the Sabak district on the Bernam River, Grantham.....	322
Investigation of the peat bogs and peat industry of Canada, 1913-14, Anrep..	322
The analysis of soils, Wild.....	322
Bureau of Soils, U. S. Department of Agriculture, Whitney.....	323
Artificial manures, 1916.....	323
Soil fertility considerations in the feeding of hogs and milch cows, Forbes....	323
Plant food deficiencies of Coastal Plain and Piedmont soils, Williams.....	323
Note on the soil of the experimental farms [in Burma], Warth.....	323
Fertilizer experiments with sugar cane on red clay soil, Gile and Carrero....	323
The residual effects of fertilizers, Bear, Salter, et al.....	324
[Experiments in Java with green manures], Van Helten.....	324
Loss of organic matter in green manuring, Boltz.....	324
Utilization of nitrogen of manure in relation to time of manuring, Sabashnikov.	325
Bat guanos, Gile and Carrero.....	325
The availability of nitrogen in garbage tankage, Schroeder.....	325
Potash in Salduro salt deposit, Gale.....	325
Action of calcium carbonate on acid phosphate, Magruder.....	325
A critique of the hypothesis of the lime-magnesia ratio, I, II, Lipman.....	326
Effect of manganese on ammonification and nitrification, Brown and Minges..	326
Commercial fertilizers, Hibbard.....	326
Analyses of commercial fertilizers, Wessels et al.....	327

## AGRICULTURAL BOTANY.

Department of botanical research, MacDougal.....	327
Artificial absorption of liquids by plants, Acqua and Jacobacci.....	328
A study of physiological balance in nutrient media, Shive.....	328
Influence of salts on secretion of diastase by <i>P. camembertii</i> , Robbins.....	328
Nitrates in sulla ( <i>Hedysarum coronarium</i> ) and other legumes, Campanile.....	329
Glucosid formation by plants, Ciamician and Ravenna.....	329
Significance of the flavone derivatives in plants, I-III, Shibata et al.....	329
Relation of oxidases and catalase to respiration in plants, Appleman.....	329
On the relation between transpiration and stomatal aperture, Darwin.....	329
The perception of heliotropic stimulus in plants, Campanile.....	330
Relation between geotropic sensitivity in roots to statoliths, Jacobacci.....	330
Relation of geotropic sensitivity in roots to statoliths, Jacobacci.....	330
The vitality of seeds buried in the soil, Beal.....	330
Mechanics of dormancy in seeds, Crocker.....	330
Foliar structure in some oaks having persistent leaves, Donati.....	330
Mesophyll structure and function in grains, Catalano.....	331
The nature of the inflorescence and fruit of <i>Pyrus malus</i> , Black.....	331
Notes on parthenocarpy, Longo.....	331
Department of experimental evolution, Davenport.....	331
A new graft hybrid, Manaresi.....	331
Significant accuracy in recording genetic data, East.....	332

	Page.
[Work with field crops], Smith.....	332
[Fertilizer experiments], De Jong.....	332
Principles of breeding certain agricultural plants.—V, Grasses, Fruwirth.....	332
Some common grasses and how to know them, MacDougall.....	333
A trial of grass mixtures, Hilgendorf.....	333
Composition of several forage grasses of German East Africa, Reich et al.....	334
<i>Medicago falcata</i> , a yellow-flowered alfalfa, Oakley and Garver.....	334
Lucern inoculation experiment, Heinrich.....	335
Alfalfa conditions in New England, Jeffers.....	335
Barley improvement, Spragg.....	335
Fasciation in maize kernels, Wolfe.....	335
Work of the Pskof experiment station for flax culture, D'Iakonov.....	335
A handbook of industrial plants in common use, Farnsworth et al.....	336
Oat breeding experiments, Pridham.....	336
Observations on potato culture, Kotelnikov.....	336
The influence of overabundant soil moisture on potato tubers, Arkhangelskiĭ.....	336
Further experiments in crossing potatoes, Wilson.....	336
Harvesting and storing potatoes, Malpeaux.....	336
The soy bean, with special reference to its utilization, Piper and Morse.....	336
Tobacco growing in the Connecticut River Valley, Smith.....	337
Improvement of Ghirka spring wheat in yield and quality, Clark.....	337
Red Rock wheat, Spragg and Clark.....	338
Methods of sowing Poltavki spring wheat, Golodets.....	338
Nitrogenous fertilizers in wheat culture, Malpeaux.....	338
A seed-testing key, Cockayne.....	338
Contribution to testing the germination of grass seeds, Kling.....	338
[The examination of beet seeds], Heinrich.....	339
Size relation between dry and soaked seed of clover and dodder, Heinrich.....	339
[Cooperative experiments in weed eradication].....	329
[ <i>Pteris aquilina</i> .—Life history and eradication], Gordon.....	339

## HORTICULTURE.

Report of the horticulturist, Kinman.....	340
The supposed deterioration of vegetables in Porto Rico, Kinman and McClelland.....	340
Managing the orchard, Moore.....	341
Winterkilling of peach buds, Thayer.....	341
Practical fig culture in Arizona, Lawrence.....	341
Composition of grapes grown in the Central and Eastern States, Alwood et al.....	342
Report of the assistant horticulturist, McClelland.....	342
Freezing-point lowering of leaf sap of <i>Persea americana</i> , Harris and Popenoe.....	343
The two groups of varieties of the Hicora pecan and self-sterility, Stuckey.....	344
Effect of cultural and climatic conditions on peppermint oil, Rabak.....	344

## FORESTRY.

The economic woods of Hawaii, MacCaughey.....	345
The uses of Formosan trees, Kanehira.....	345
The assortment ratios of spruce, silver fir, and beech, Flury.....	345
Influence of intensity of thinnings on yield of young fir, Mer.....	345
Douglas fir fiber, with special reference to length, Lee and Smith.....	345
Some characteristics of slash pine, Mattoon.....	345
Seeding of Hevea at different altitudes on Gunong Angsi, Spring.....	345
Ecology of sal.—II, Seedling reproduction, Hole and Singh.....	345
The forests and streams, Da Silveira.....	346
The effect of forests upon water circulation, Beekman.....	346
National Forest organization, Wynne.....	346
Conversion methods in forests of Chaux and Faye de la Montrond, MacMillan.....	346
Yearbook of the department of forestry.....	346
Report on forest administration in Bengal 1914-1915, Muriel.....	346
Forestry in India from a Canadian point of view, MacMillan.....	346
Passing views of forestry in British South Africa, MacMillan.....	346
Report of the director of forests, Jolly.....	346
China's forest laws, Sherfesse.....	347

## DISEASES OF PLANTS.

	Page.
[Serious plant diseases in 1914], Reddick.....	347
Report of the plant pathologist, Brandes.....	347
[Report on plant pathology], Knowles.....	347
Report of the imperial mycologist, Shaw.....	348
Report on the first two years' working of the plant protection law, Storey.....	348
Studies on a Fusarium disease of corn and sorghum, Pammel et al.....	348
Clover sickness, Amos.....	348
[Ufra disease], Hector.....	349
Resistance in tobacco to the root rot disease, Johnson.....	349
Host plants of <i>Thielavia basicola</i> , Johnson.....	349
Diseases of vegetables, Jagger.....	349
Cucumber mosaic disease, Gilbert.....	349
A new infectious mosaic disease of cucumber, Doolittle.....	349
Experiments with the cucumber mosaic disease, Jagger.....	350
Rotting of greenhouse lettuce, Jagger.....	350
Tomato blight, Heald.....	350
A troublesome disease on winter tomatoes, Howitt and Stone.....	350
Powdery mildew demonstrations on apple, grape, and peach during 1915, Powell.....	350
Comparative dusting and spraying experiments, Reddick and Crosby.....	351
Note on apple root rot in Virginia, Crabill.....	351
Apple rosette, Morris.....	351
Sulphur paste as a spray for peaches, Reddick.....	351
Pear blight ( <i>Bacillus amylovorus</i> ), Morrison.....	351
Rôle of insects in dissemination of fire blight bacteria, Stewart and Leonard.....	351
Resistance of Prunus to inoculation with <i>Bacterium tumefaciens</i> , Smith.....	352
A Porto Rican disease of bananas, Fawcett.....	352
Citrus canker investigations, Newell.....	352
Means of identifying citrus canker, Jehle.....	352
Sour scab of citrus in Florida, and its prevention, Grossenbacher.....	352
Diseases of forest and shade trees, Babcock.....	353
An outbreak of white pine blister rust in Ontario, Howitt and McCubbin.....	353
Methods of preparation and relative value of Bordeaux mixtures, Butler.....	353

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

The larger North American mammals, Nelson.....	354
The feeding habits of the rook ( <i>Corvus frugilegus</i> ), Leigh.....	354
The rat and infantile paralysis: A theory, Richardson.....	354
The animal parasites of man, Braun and Seifert.....	354
A new and economically important tapeworm, <i>Multiceps gaigeri</i> , Hall.....	354
Report of the entomologist, Van Zwaluwenburg.....	354
[Papers on insects and insect control].....	355
[Report on] economic zoology.....	355
Report of the tobacco insect investigations, Merrill.....	355
Insect pests of tea in northeast India during the season 1915, Andrews.....	355
The orthopteroid insects of the Philippine Islands, Bruner.....	355
Second campaign against locusts ( <i>Stauronotus maroccanus</i> ) in Algeria, Béguet.....	356
Third campaign against locusts ( <i>Schistocerca peregrina</i> ), Béguet et al.....	356
The native food plants of the apple red bugs, Cushman.....	356
Bedbugs and relapsing fever, Stephansky.....	356
The bloodsucking Hemiptera of Central America, Neiva.....	356
Temperature necessary for the destruction of lice and their eggs, Bacot.....	356
Rosy apple aphid, Baker and Turner.....	356
A synopsis of the genus <i>Calaphis</i> , Baker.....	357
The development of the <i>Phylloxera vastatrix</i> leaf gall, Rosen.....	357
The San José scale ( <i>Aspidiotus perniciosus</i> ), Peairs and Merrill.....	357
Control of gray scale ( <i>Coccus citricola</i> ) in San Joaquin Valley, Cundiff.....	357
Two destructive fall caterpillars, Houser.....	358
<i>Laspeyresia molesta</i> , an important enemy of peach, Quaintance and Wood.....	358
A new mosquito from the eastern United States, Knab.....	359
The fowl midge ( <i>Simulium nigratarsis</i> ), Mally.....	359
Egg disposal in <i>Dermatobia hominis</i> , Knab.....	359
The tachinid genus <i>Argyrophylax</i> , Walton.....	359
Notes on the larvæ of <i>Euresta notata</i> , Hutchison.....	359
The parasitic Diptera of Africa, Rodhain and Bequaert.....	359

	Page.
Researches on the larvæ of cyclorrhaphous Diptera, Keilin.....	359
The bionomics of <i>Pollenia rudis</i> in America, Webb and Hutchison.....	359
A curious formation of a fungus occurring on a fly, Howard.....	360
A new parasite on sheep maggot flies, Froggatt.....	360
Ambrosia beetles or pin-hole and shot-hole borers, Beeson.....	360
Forest longicorn beetles and their parasites, Froggatt.....	360
A new species of weevil injuring orchids, Barber.....	360
<i>Pristocera armifera</i> parasitic on <i>Limonius agonus</i> , Hyslop.....	360
Notes on <i>Dianthidium arizonicum</i> , Middleton.....	360

## FOODS—HUMAN NUTRITION.

Dietary deficiencies of the maize kernel, McCollum et al.....	360
Feeding proteins of wheat kernel at different planes of intake, McCollum et al.....	361
The drying for milling purposes of damp and garlicky wheat, Cox.....	361
Skim milk in the nutrition of adults, Moussu.....	362
Chinese preserved eggs—pidan, Blunt and Wang.....	362
Flavoring extracts, Lawall and Forman.....	362
[Food and drug inspection], Ladd and Johnson.....	362
Twelfth annual report of the dairy, food, and oil commissioner, Groshon.....	363
The economical ration for the times, Bolduan.....	363
How to feed the family for health and efficiency, Rich.....	363
The feeding of prisoners and sanitary conditions in German camps, Guillaume.....	363
[Food of the natives of Mailu, British New Guinea], Malinowski.....	363
The control of hunger in health and disease, Carlson.....	363
Results of studies on vitamins and efficiency diseases, 1913-1915, Funk.....	363
The transmissibility of pellagra to the human subject, Goldberger.....	363
Experimental scurvy produced by milk and milk products, Moore and Jackson.....	363
Urea content of blood and tissues on an exclusive oat diet, Lewis and Karr.....	364
Mechanism of sparing action of carbohydrates on protein metabolism, Kocher.....	364
Effect on nitrogen partition of substituting alcohol for sucrose, Hammett.....	364
Concerning the utilization of inosit in the animal organism, I, II.....	365
The distribution of the lipoids ("fat") in human blood, Bloor.....	365
Urinary and fecal output of calcium in normal men, Nelson and Williams.....	365
The calcium and the magnesium content of normal urine, Nelson and Burns.....	366
Contribution to the knowledge of the enzymes of the large intestine, Maestrini.....	366

## ANIMAL PRODUCTION.

International catalogue of scientific literature. L.—General Biology.....	366
Experimental studies on growth, VIII, Robertson.....	366
Net energy values for ruminants, Armsby and Fries.....	367
Net energy values of American feeding stuffs, Armsby and Putney.....	367
War feeding stuffs, Popp.....	367
The industrial manufacture of war feeding stuffs, Popp.....	367
Cotton-seed meal as an incomplete food, Wells and Ewing.....	367
Digestibility and feeding value of vegetable-ivory meal, Beals and Lindsey.....	367
Composition and food value of blood meal, Hansson.....	369
Investigations on the growth of reindeer moss, Nissen.....	369
Feeding dairy calves in California, Wool and Voorhies.....	369
Feeding calves with skim milk and partially hydrolyzed starch, Edin.....	370
Value of alfalfa and other green feed in hog raising, Hansson.....	370
Long-bodied brood sows, Wentworth.....	371
Breeding studies of the large white English hog, Wriedt.....	371
Correlation between cannon bone in offspring and age of parents, Wriedt.....	371
Mules that breed, Lloyd-Jones.....	372
Amino-acid content of diet and growth of chickens, Osborne, Mendel, et al.....	372
Cotton-seed meal—a good feed for laying hens, Clayton.....	373
Rations for laying hens in winter, Buss.....	373
The logic of the winter feeding schedule, Shoup.....	373

## DAIRY FARMING—DAIRYING.

Computation of dairy rations, Putney and Armsby.....	374
Oranges for dairy cows, Hooper.....	374
Effect on milk and butter of yeast and cotton meal, Cranfield and Taylor.....	374

	Page.
Variations in the composition of skim milk, Perkins.....	374
The significance of the act of milking, Crowther.....	375
Iowa educational market milk contest, Hammer and Hauser.....	375
Safeguarding nature's most valuable food—milk, North.....	375
The cost of milk production, Mackintosh.....	376
Some aspects of the dairying industry of England and Wales, Gavin.....	376
The marketing of Wisconsin butter, Hibbard and Hobson.....	376
Experiments on the preparation of homemade rennet, Todd and Cornish.....	378
The improved system of selling cheese, Sammis.....	378

## VETERINARY MEDICINE.

Outline of lectures in special pathology, Burnett.....	378
Proceedings under the diseases of animals acts 1911-1914.....	378
Report for 1915 of principal of Royal Veterinary College, McFadyean.....	378
The Pharmacopœia of the United States of America.....	378
The National Formulary.....	378
Magnesium hypochlorite in surgery, Dubard.....	379
A comparison of the Hygienic Laboratory and Rideal-Walker tests, Walker....	379
A method of anaerobic plating permitting observation of growth, Jones.....	379
Comparative study of colon bacilli isolated from horse, cow, and man, Murray..	379
Rôle of blood fluids in digestion of certain bacteria and corpuscles, Douglas...	379
Permeability of gastro-intestinal wall to <i>Sporothrix schenckii</i> , Davis.....	379
Laboratory infection by a bovine strain of <i>Bacillus enteritidis</i> , Meyer.....	380
The antibodies of spores, Chimera.....	380
The precipitation reaction with silkworm caterpillar immune serum, Aoki. . .	380
The agglutinin reaction in the examination of silkworms, Aoki and Chigasaki.	380
Biologic reactions of vegetable proteins.—VIII, Elsesser.....	380
Experiments with the Abderhalden dialysis procedure, Otto and Blumenthal..	381
The complement content of Eck-fistula dogs, Sherwood, Smith, and West.....	381
A cutaneous reaction in canine distemper, Kolmer et al.....	381
Anaphylactic skin reactions in relation to immunity, IV, Kolmer et al.....	382
Changes in the blood count in dourine, Popesco.....	382
Virulence of blood of animals with foot-and-mouth disease, Cosco and Aguzzi..	382
The K. H. reaction in glanders, Kranich and Kliem.....	382
Johne's disease, M'Fadyean and Sheather.....	382
Milk in relation to Mediterranean fever, Porcher and Godard.....	382
Hereditary transmission of rabies, Konradi.....	383
A modification of the Hygienic Laboratory method for tetanus toxin, Wilcox...	383
A new culture medium for the tubercle bacillus, Williams and Burdick.....	383
The combined and follow-up systems of tuberculin testing, Hart and Traum..	383
Studies in infectious abortion in cattle, Giltner et al.....	383
Contagious broncho-pneumonia caused by <i>Bacillus coli communis</i> , Stanton.....	384
The use of arhenal for the treatment of Texas fever, Aghion.....	384
Studies on hog cholera with reference to <i>Spirochæta hyos</i> , King and Drake.....	384
Illinois hog cholera serum plant.....	384
Enterohepatitis or blackhead in turkeys, Higgins.....	384
Enterohepatitis or blackhead and raising turkeys, Higgins.....	384

## RURAL ENGINEERING.

Proceedings of the Ohio Engineering Society, February 9, 10, 11, 1916.....	384
Laws of Idaho relative to water and irrigation, Hindman.....	384
Run-off and mean flow of some Texas streams, Taylor.....	384
Warner Valley and White River Projects, Whistler and Lewis.....	385
The saving of irrigation water in wheat growing, Howard.....	385
[Road laws].....	386
Report of state engineer [of Arizona] to state highway commission, Cobb.....	386
The financial side of road improvement, Coghlan.....	386
Demonstration roads at A. and M. College of Texas, Morrison.....	386
Earth roads, Morrison.....	386
Gravel roads, Coghlan.....	386
Highway bridges and culverts, Coghlan.....	386
Convict labor for road work, Pennybacker, Fairbank and Draper.....	386
Experimental studies of vacuum juice heaters, Kerr and Webre.....	387
Tests of the power and steam consumption of sugar factories, Kerr et al.....	388
Some experiments on pulling loads, with a discussion of the results, Brown....	388

	Page.
Second series of tests of mechanical cultivation, Marre.....	389
Plans and suggestions for a modern milk house.....	390
Inexpensive plumbing for farm kitchens, Etherton.....	390
The water supply of the farmhouse, Walters.....	390
Water supply system for the farm home, Riley.....	300
Sewage treatment in small communities without sewerage system, Hansen....	390

## RURAL ECONOMICS.

Agricultural economics, Nourse.....	390
The relationship of New England agriculture to manufacturing, Butterfield...	391
Farm management studies in eastern Nebraska, Filley.....	391
Rural land ownership among the negroes of Virginia, Bitting.....	392
Facts about land.....	392
Farm work for discharged soldiers, Moore.....	392
Rural cooperation in Denmark, Desbons.....	392
The result of an experiment in agricultural credit in Tuscany, Virgili.....	392
Report of the Agricultural Organization Society for 1916.....	392
[Report on the working of the cooperative credit societies], Nath.....	392
Second annual report of the department of foods and markets, 1915.....	392
Monthly crop report.....	392
Food and raw material requirements of the United Kingdom.....	392
Prices and supplies of agricultural produce in England and Wales, Rew.....	393
Agricultural statistics of Ireland, with detailed report for 1914.....	393

## EXPERIMENT STATION RECORD.

VOL. 36.

MARCH, 1917.

No. 4.

---

There are three distinct landmarks in the development of agricultural inquiry in this country. The first was set up when one of the States became sufficiently convinced of the concrete value of agricultural experimentation to the public to establish an experiment station modeled on those of Europe, thus furnishing an example which other States soon began to follow. The second was when the Nation set its seal of approval on these stations, something over twenty years after the first one had been established, and made the system national by providing funds for a station in every State and Territory. The third came nearly twenty years later, in the passage of the Adams Act, which brought with it a new era of intensive searching for fundamental truth.

It is now thirty years since the American system of stations was established under the Hatch Act. It is a little more than ten years since they expanded their operations as a result of the Adams Act. That act passed in the spring of 1906 but had to await an appropriation which came at the very end of the fiscal year—too late for work to be started under it. Hence the year 1907 marked its beginning, and it was not until four years later that the appropriation reached its full amount. For only about half the time since its passage, therefore, has the full appropriation been available.

A decade is a relatively short time in which to measure an influence or a development in science, especially the result of research activity; but the period has brought so many changes and so much progress that it is perhaps worth while to consider these briefly. It has been an era of great activity—one of construction and development, and of large accomplishment. Ideas have been shaped, standards set and accepted, and foundations laid, which have premeated to every State in the Union; and from these have already resulted a new conception of the field and higher function of an experiment station.

From the inception of the experiment stations the question has been working itself out as to what an experiment station is—its peculiar field and function irrespective of special duties assigned to

it under State laws. The American experiment station is a product of American institutions and American ideals. It has no exact counterpart. It has developed as a response to public demands which its own work has in large measure created. Thus, while primarily an agency for acquiring useful and accurate information, the facts it has adduced have led to bestowing upon it police powers for protection of the agricultural industry, and later multiplying its activities in the dissemination of information, conducting propaganda for new branches of the industry or new localities, and in general serving the agricultural interests in a quite broad capacity.

It is interesting to note that the idea of the experiment station as a research institution is almost as old as the American stations. In the first report of the New York State Station, for 1883, Dr. Sturtevant explained that "the object of the station is to discover, verify, and disseminate;" and he showed a very modern view of the scope of each kind of activity. He said: "The leading aim of an experimental station such as ours must be by experimental study of the most careful kind to obtain knowledge of the action of the laws which find application in agriculture, and to devise methods for the application of the knowledge gained, in order that in practical farming waste of means and effort may be diminished and gain may be increased, and thus profits be forwarded."

The reason for agricultural investigation and experiment is that our information may be sound, that reason may prevail, that man may act and conduct his operations rationally. In a large sense it is a study of the relationship of cause and effect. Wherever an effect is observed there has been a cause, and this cause becomes the object of study. If the purpose is to produce a certain effect, knowledge of the phenomena which cause such effects or influence them must be acquired before the effort becomes more than a hit-or-miss process. The scientific method is that which takes account of all the forces acting. To know the law we must understand the law, and this is equally true of a fact or a spray mixture or a method of making cheese.

Science, whether pure or applied, proceeds on the principle that the same causes acting under precisely the same conditions will produce exactly the same effects. In other words, that nature is ordered by law and that there is nothing arbitrary or capricious in its operations. Chance plays no part, and what we observe is a lawful, natural consequence of causes which we may or may not understand. When we do not understand why certain events occur, it means that we do not understand the forces which acted to produce the event. But there is nothing fortuitous or incapable of being understood

through science, either in the elaboration of starch in the growing plant or the benefits from fall plowing.

In the attempt to understand science and its methods much inspiration and help, as well as subject matter, have naturally been borrowed from the older sciences. But the process can not rest there. Agricultural science must itself be productive of scientific results and theories; hence the Adams Act. This Act sprung from a realization that empirical facts and unproved theories were not a safe or sufficient basis for guidance in agricultural teaching, but that a more severe type of inquiry was necessary to develop both the fact and the reason back of it. These and their relationships need to be known before they can be understood and intelligently employed.

The Adams Act was not simply supplementary to the Hatch Act, to enable more of the same kind of work to be done; it was this fact that gave it directing power and has made it so potent in its influence. It was, as its language tried to express, an act to provide for investigation of a high and fundamental order, because progress under the Hatch Act had established the necessity for fundamental study and the activity had gone about as far as it could without additional funds.

The Hatch Act permitted such study and an important amount had been done under it, but it did not limit the activities of the stations to that grade, or so clearly and specifically aim at providing for inquiry which should be original and searching, according to the accepted standards of scientific research. When the Adams Act passed it was characterized as being "the greatest opportunity for continued systematic research along agricultural lines which has ever been presented in any country," and time has borne out this estimate of it. It has given a great impetus to investigation, and it has transformed the American station from being a liberal borrower to being a large and important producer in agricultural science.

The acceptance at the outset of the purpose of the Adams Act as being the promotion of investigation and experiment of research grade and original in character has tended to make the designation "Adams fund project" a sort of hall-mark of quality in experiment station activity. Because the act has consistently represented a high standard, investigators have been ambitious to have projects accepted under it, and have felt a pride in being associated with the Adams fund. In a sense it has made the Adams fund roll regarded as an honor roll.

The necessity of making the investigations thorough and exact in order that they might be dependable and capable of scientific interpretation, has resulted in more care in the matter of methods. At

present there is a far more adequate realization of the limitations of some of the common methods of experimentation than formerly, and recognition that they embody many modifying factors not measured or accounted for. There is a more critical examination of the sources of error, in both observation and interpretation, and a more guarded drawing of broad conclusions.

The standards of the Adams fund studies have affected all forms of station activity. More is expected of experiment station work than formerly—not in quantity but in quality. In the search for new light quantity takes a secondary place. It is the quality, the thoroughness, the reliability of the work that counts. Hasty, unwarranted conclusions have proved expensive in the end, and they have delayed progress by taking men's time to upset them.

These higher standards and expectations have been accompanied by a change in the nature of the problems. The limit of the things which could be found out through accumulated experience or simple experiments and observations has been reached in most lines. These findings have brought the investigator face to face with the more fundamental and intricate questions which require refined and elaborate methods and special research ability for their solution. From this change has followed a far-reaching change in the professional requirements for station work. The qualifications are set higher and made more exacting. It has come to be realized that the measure of efficiency of an experiment station is the sum of the efficiency of its workers.

In 1906, when the Adams Act was passed, the American stations employed 950 persons, of whom 434 did more or less teaching; the majority of those who did no teaching were of the assistant grade or not directly participants in investigation. In 1916 the station forces numbered 1,866, of whom 933 taught to some extent in the colleges, the amount of teaching being very generally reduced. Thus the opportunity for concentrated, continuous effort has increased materially. Furthermore, the investigators have been encouraged to specialize more closely in their studies, at least at any given time. This has become necessary from the nature of the problems, which require more specialized attention.

Other obstacles to research have been reduced or overcome, and the opportunities enlarged. The funds of the stations have increased from a little over two millions when the Adams Act was passed (including the first allotment of it) to considerably over five millions in 1916. Public sentiment for thorough-going investigation has largely developed. The public has come to understand that because a thing or a piece of work is theoretical it is not necessarily unpractical. "Theoretical" and "unpractical" are no longer viewed with suspicion as being synonyms. Some of the most intricate types of in-

vestigation have proved to be highly practical. It is a mark of real progress in public confidence when a station can secure a State appropriation and embark on the most technical studies in the theory of animal nutrition, the relation of ash constituents to nutrition and growth of animals, or the fundamentals of breeding sex-linked characters, with opportunity to pursue its work undisturbed. Indeed, the kind of work which is now in large measure occupying the stations shows how far we have come and the large freedom allowed, provided the ultimate aim is right.

The inspection work has become a much less conspicuous feature of the stations, and has been so organized as to avoid interference with the work of investigation and experiment. Research publications have increased many fold in the last ten years. A considerable number of stations have established research series of bulletins, or otherwise differentiated their technical publications from the regular bulletins intended for the general public. The publication of scientific papers in current journals of this country and Europe has become very common, where formerly it was quite exceptional. The *Journal of Agricultural Research* has been established and furnishes a special medium for station contributions.

Progress is seen also in the organization of station work. It is being developed more largely out of a constructive purpose and in accordance with a definite plan. It is not contingent on something turning up or on what may occur to various members of the staff to undertake. The subject attacked are to considerable extent a part of a general plan for the station, recognizing that it can not cover all questions at any one time, and that a selection must be made based in large measure upon the special requirements in the State. The station is made up of its departments, but it is larger than any single department and in many respects it must act as a unit.

The project system was practically inaugurated with the beginning of activities under the Adams Act. It is an attempt to formulate in an orderly way the purpose and general plan of each separate undertaking. It involves care and thoughtful study in the outlining of new work, in order to take full account of what has been done previously, and to give the work originality and direction. Some time is required in preparation, but this is by no means lost, since it gives force and method to the attack. It is characteristic of all investigation that it is purposeful and is ordered, to the best of ability. The project system guards against aimless, ill-considered, premature undertakings, and it provides a basis, not only for judging of the character of new ventures but of the requirements in carrying them out.

The project system has been extended in large measure to all the activities of the stations, irrespective of the funds from which they are supported. As an administrative measure, it has been found to present many advantages, and where adopted it has met with general satisfaction, as providing a helpful businesslike method of procedure.

Partly as a result of this plan, more systematic effort is now made to secure progress reports of some sort upon the various features of investigation, and to effect the prompt recording and digestion of the data, either for publication or for safe preservation. Report writing is tedious to many workers, especially those who are crowded with work as most station men are, and there is some tendency to allow data to accumulate in a form subject to loss or which would make them difficult for anyone else to work over. There has been considerable waste from this source in the past, and the effort to bring about more systematic procedure is recognized as an important advance.

As to the tangible product of the research conducted under the Adams Act, space will permit reference to only a few features. Where the product is so large it is difficult to make selection, and in any attempt at citing examples there is danger of doing injustice or conferring a wrong impression. For, manifestly, some of the most important pieces of investigation have marked significant steps in the progress toward final conclusions, rather than in themselves having a conspicuous practical end; and many things omitted are quite as important as the few mentioned.

Some of the most significant investigation has been in the field of animal nutrition, of a nature which is to some extent destructive or corrective of former views, but constructive in giving a more accurate insight into the theory of nutrition and the relative value of food constituents. It has been found, contrary to the former belief, that like amounts of food ingredients do not necessarily produce like effects—that there are differences in the constitution of protein from different sources, that not only the kind of protein but the presence of certain amino acids is important, and that apparently other constituents, notably in the fat, have a distinct although not yet fully understood relation to growth.

Similarly, the mineral nutrition of animals is found to be a far more important matter than was formerly suspected; and much light has been thrown on the use made of food by animals at different ages and on different planes of nutrition. The comparative feeding experiment has been largely replaced, except for economic purposes. An Institute of Animal Nutrition has been established in one of the States, and in upwards of a half dozen other States fundamental feeding investigations have been developed on an extensive scale.

The results are to a considerable extent in the theoretical stage as yet, but will ultimately modify in important ways the practical directions for feeding.

The theory of plant and animal breeding will be recognized as another conspicuous feature of the station investigation. In this line knowledge of the theory and practice of plant breeding has been very largely increased by the extensive studies made with various classes of plants and animals, and from different points of view. The investigation has largely changed from the earlier attempts to secure something better, to the search for a more thorough understanding of principles on which the theory and practice may be further perfected and developed. Incidentally many improved strains of plants and animals have been secured, either giving larger production, greater immunity, or otherwise possessing important economic qualities.

The extensive study of inheritance in egg production illustrates a type of work with animals, which has widespread practical value. The experiments in the transmission of characters in mule breeding are unique, and have given an intelligent basis for such operations. In hybridization work with plants a number of hardy plums and other improved fruits have been developed, and valuable qualities of cereals, corn, and cotton have been fixed and perpetuated by line selection. In combating plant diseases the knowledge of breeding has been turned to excellent account, as for example in producing strains of clover immune to anthracnose, cabbage immune to wilt or yellows, and varieties of cereals resistant to diseases.

Many seed-borne diseases have been brought under control by discovery of their weak points. It has been found, for example, that cotton anthracnose can be prevented by delinting the seed with sulphuric acid or treatment with hot water, which destroys the organism, and that bean anthracnose can be prevented in the South by growing the bean crop for seed during the summer, when the fungus can not withstand the hot weather. Studies of the apple rust have shown that it may be controlled by destruction of cedar trees which serve as the alternate host of the fungus, and this finding has resulted in favorable legislation. The extensive studies of the rusts are furnishing a broad basis for economic studies in relation to this class of diseases.

Dairying has to its credit a considerable list of projects which have resulted in important advancements. For example, the studies in cheese ripening and on the rôle of acid in cheese making have led to a new method of cheese manufacturing in which pasteurized milk is employed, using artificial ripeners. This has reduced cheese making more largely to a mechanical process, easily controlled, requiring

less skilled labor, and yielding a more uniform product. The method avoids the loss in yield and quality due to defective milk, gives a more uniform and sanitary product, and calls for less cold storage in curing.

The determination of the coloring matter in milk might seem at first to have only theoretical interest, but when followed by a similar study of feeds which discloses the relation of certain kinds to light and dark color in milk, cream, and butter, it is seen to have a very practical significance. Similarly, studies of the influence of feed in modifying the chemical and physical properties of butter, while in themselves highly technical, have led to important practical results. To cite an illustration, silage is found to counteract the hardening effect of cottonseed meal upon butter, exercising an opposite effect to cottonseed meal on the fat constants.

Two interesting pieces of work which have a direct application in the feeding of milk to children have dealt with the study of the fat globules and the casein of milk from Holstein and Ayrshire cows as compared with that from Jersey and Guernsey breeds. The size of the fat globules was not found to be a factor. In the case of the first two breeds the casein is more decidedly flocculated, and as it is not so easily curdled in the stomach is apparently more tolerant to infants.

Continued work in dairy bacteriology has served to throw much light on the sources of bacterial contamination of milk and dairy products and to modify some of the earlier precautions prescribed, especially since the cow and the utensils are found to be far more important sources of contamination than the stable and dust.

In horticulture, studies on the factors connected with bud formation are at length yielding light bearing upon the possibilities of control; and other extensive studies in progress have reference to the interrelation of stock and scion, the periodicity of growth in trees, factors which stimulate growth, the specific effects of fertilizers, and hardiness as correlated with structure.

From the long list of successful life history and other studies in economic entomology, the working out of the number of broods of certain insects in different localities, the finding that the woolly aphis of the apple passes part of its life on the elm, producing an affection there, that the sugar-beet plant louse spends some of its life history on the cottonwood tree, the influence of soil moisture and flooding on the control of sugar-beet root louse, may be cited as striking examples of the application of technical studies in suggesting means of control.

The work with fungicides and insecticides, their preparation and use, the manner in which they affect insects, and the conditions under

which they injuriously affect foliage, has been very extensive and has in large measure reduced the practice of spraying to a science. In this connection the working out of the methods of dust spraying and its advantages under certain conditions should be mentioned. After years of unsatisfactory results in the use of gaseous insecticides in mills and grain elevators, striking results have been obtained in ridding these buildings of insect pests by the simple use of heat.

The study on bacillary white diarrhea in poultry and the means by which it spreads, and the finding of a reliable method of diagnosis by which it may be eliminated from breeding flocks, have led to a general campaign against the disease in several States.

The above will be recognized merely as examples in a long list of investigations which have already been productive of important results or are pointing to such conclusions. It is one of the attributes of a scientific discovery that the credit for it usually can not be ascribed entirely to a single person or institution. It develops in part from work which has gone before and has made possible the new or particular application. This is often true of the examples here cited, which recognizes that the stations are not working alone in the great field of agricultural inquiry.

There are at present nearly five hundred distinct projects being conducted at the stations with the partial or complete support of the Adams fund. This indicates the extent of the enterprise. These projects are in charge of three hundred and eighty leaders and associates. No two projects are alike; each is an individual undertaking. Their diversity shows how far they are removed from any standardizing influence.

Such are some of the developments and evidences of research activity which have come in the past decade. Although this progress can not all be ascribed to the Adams Act, it is due in considerable measure to its direct influence along with the continued experience in investigation. The field has grown to be much larger and the task much deeper than seemed at first. Perhaps one of the greatest truths borne in upon us is the realization that the task is almost endless—that we can never touch bottom in all there is to know about the simplest subjects with which our investigation concerns itself.

Agricultural research has as yet only "stirred a few grains of sand on the shore," but it has made a beginning which seems large in the perspective in which it is viewed and in what it promises. The stations have made some contributions to the theoretical rubbish-heap, which is to their credit, for it proves that originality has been

exercised. And they have made highly important contributions to the knowledge of their day and generation.

In some respects we have learned how not to know, and have set our faces in the right direction—the direction of making our knowledge exact in so far as it goes and as the status of science permits. We have learned not to hesitate to abandon or modify practical and theoretical views on the basis of new light, and so to make our work progressive and constructive by building fact upon fact and sequence upon sequence.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Grain of the tobacco leaf**, C. S. RIDGWAY (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 6, pp. 269-288, pls. 3, figs. 2).—The results of the study reported show that the bodies which cause the grain in cigar tobacco consist of from one to several leaf cells filled with a crystalline substance. These bodies are microscopically visible in ordinary transmitted light, but are more prominent when examined with polarized light. Five forms or types of grain were recognized, but their significance was not investigated. Cryptocrystalline calcium oxalate contained in certain cells in the various tissues of the leaf and single small prismatic crystals scattered evenly throughout the leaf were also identified in the tobacco.

The grain was separated from the leaf by a process of mechanical analysis described in detail. Incidentally in the separation of the grains it was found that, using a sample of 70 gm., 33 per cent of the weight represented midribs, 48 per cent soft tissue, 8 per cent veins (other than the ribs), and 11 per cent the grain. It is noted, however, that these results are only approximate. On analysis the grain bodies were found to have the following percentage composition: Moisture, 8.06; pure ash, 40.26; potassium oxid, 3.42; calcium oxid, 26.34; magnesium oxid, 3.13; oxalic acid, 0.82; citric acid, 22.38; and malic acid, 13.58. Analyses of the leaf web, large vein excluding midrib, and small vein are also submitted. The analytical data indicate that the grain is composed chiefly of calcium with a small amount of magnesium and potassium in combination with citric and malic acids rather than with oxalic acid. Normal calcium malate was identified by petrographic methods.

The grain was found not to be responsible for the marked hygroscopic properties of the tobacco, since the amount of water absorbed by it from a moist atmosphere was less than that absorbed by the other kinds of material. The small veins of the leaf showed the greatest hygroscopicity.

"The grain bodies of tobacco are developed in the course of post-mortem changes which take place during the process of curing and continue during fermentation. A microscopically visible change consists of a more or less complete aggregation of the grain-forming substance of all the cells into certain groups of cells. The factors determining the location of these groups are unknown.

"In the tobacco studied a correlation was found between the grain and burning properties. It is believed that the substances contained in the grain bodies are injurious to the burn, and that the quality of the latter is dependent upon the degree to which the former are aggregated into definite bodies sufficiently separated, one from the other, to permit a considerable fire-carrying zone of cells, emptied of grain material, around each. The influence of the degree of aggregation of the grain substance upon the color, texture, and elasticity of the leaf has not yet been thoroughly investigated."

Tabulated and graphical analytical data relative to the burning quality of the tobacco grown on plats to which various kinds and amounts of fertilizers were applied are submitted.

**The chemical composition of lime-sulphur animal dips**, R. M. CHAPIN (*U. S. Dept. Agr. Bul. 451 (1916), pp. 16*).—A number of lime-sulphur solutions have been analyzed by the methods previously described by the author (E. S. R.,

35, p. 207) with the view of determining the effect of storage; of lime added after dilution; of varying the lime-sulphur ratio, the period of boiling, and the concentration; the occurrence and relation of calcium sulphite; the ratio of polysulphid to thiosulphate; the lower polysulphids and the effect of an excess of lime; and the higher polysulphids and the effect of oxidation.

The reactions, some of which are reversible, which determine the composition of lime-sulphur solutions are rather numerous. The points of equilibrium vary according as the solution is hot or cold, dilute or concentrated, or exposed to the influence of other varying conditions. "Under such circumstances the only way in which laboratory studies can be of practical value is by so thoroughly establishing the fundamental principles involved and the effect of varying conditions upon the relative importance of such principles as to afford a sound basis for reasoning."

The general reactions between lime and sulphur on boiling with water are indicated as follows:

All lime-sulphur solutions are considered to be subject to hydrolytic decomposition according to the following equation, the equilibrium being destroyed by the reaction proceeding to the right with a rise of temperature:

The products on the right side of the equation further react, giving, in the case of  $\text{CaS}_6$ ,

"A well-boiled solution, not originally made with an excess of lime, can never under any circumstances possess a plus reaction figure—that is, it can not contain calcium hydroxid in excess of monosulphur. If originally made with an excess of lime or if not boiled long enough, excess lime is at first present in solution. But if such a preparation be allowed to stand quietly and cool off in the cooking vat, the indications are that the undissolved lime soon settles down, while the small amount of dissolved lime rapidly reacts with polysulphur according to equation 2, so that in this case, also, unless the cooled solution is again stirred up with the sediment, a plus reaction figure can never be present in the end. But such a solution will naturally contain a notable amount of tetrasulphid."

It is indicated that with an increasing concentration the time of boiling should also be increased. "With increasing concentration the utilization of both lime and sulphur possibly becomes less nearly complete, and also the polysulphids formed possibly contain a somewhat less proportion of pentasulphid. But the apparent effect might have been produced simply by insufficient boiling, and in any event it is of no material significance in comparison with the practical importance of putting out proprietary preparations in highly concentrated form.

"Finished solutions, if stored over sediment which contains free lime, will naturally tend to maintain a plus reaction figure, and will undergo changes attributable to the slow progress of reactions 1 and 2. If decanted from sediment and preserved from access of air, only two slight changes are noticeable; first, the progress of equation 5 until a certain concentration of hydrogen sulphid is reached, when equilibrium is established according to equation 4; second, an apparent slight drop in the thiosulphate figure, for which no explanation is offered, since the phenomenon appeared too quantitatively insignificant to warrant special investigation. Both changes, in fact, are so slight as to be entirely negligible for practical purposes and under ordinary conditions."

The cause of the slight discrepancies between the laboratory experiments and the theoretical results calculated from the equations is discussed. The methods of analysis used are deemed to be adequate in scope and accuracy, and also to be practical. Any loss is considered to arise chiefly during manipulation of the solutions through oxidation, and could be eliminated only by manipulating in an atmosphere of some inert gas.

A formula for preparing an animal dip in which 8 lbs. of quicklime, 18 lbs. of sulphur, and somewhat more than 10 gal. of water are boiled for one hour is submitted.

**The arsenates of lead, I,** C. C. McDONNELL and C. M. SMITH (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2027-2038).—Mono-lead arsenate ( $\text{PbH}_2(\text{AsO}_4)_2$ ) was prepared, and its physical and chemical properties are described. The methods of preparing crystalline di-lead arsenate ( $\text{PbHAsO}_4$ ) are reviewed, and its physical and chemical properties fully described. Crystallized tri-lead arsenate, lead metarsenate, and di-lead pyroarsenate were also prepared and their physical and chemical properties noted.

**Lead arsenates.**—A study of the factors controlling the reactions of lead nitrate and lead acetate with disodium arsenate, G. E. SMITH (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2014-2027).—From a study at the Montaua Experiment Station of the factors controlling the reactions of lead nitrate and lead acetate with disodium arsenate, the author concludes that "the lead arsenates produced are mixtures of diplumbic arsenate ( $\text{PbHAsO}_4$ ) and lead hydroxyarsenate ( $\text{Pb}_2\text{OH}(\text{AsO}_4)_3$ ). The products of the reactions at low temperatures, when the reactions have come to an equilibrium, whether lead acetate or lead nitrate is used consist principally of diplumbic arsenate. The products of the reactions at infinite dilutions (less than 1/1,000-molar), whether lead acetate or lead nitrate is used, consist principally of lead hydroxyarsenate if the precipitates are filtered immediately after the precipitation. The precipitate that is first formed is lead hydroxyarsenate; diplumbic arsenate is produced by a secondary reaction."

With an increase of alkaline disodium arsenate greater amounts of lead hydroxyarsenate are produced. As the concentration increases the relative amount of diplumbic arsenate increases. With an increase in temperature more of the hydroxyarsenate is formed.

The procedures used for the preparation of the pure reagents and the materials studied are described in detail.

**Researches on organic periodids.—II, Periodids of antipyrin, iodoantipyrin, and pyramidone,** W. O. EMERY and S. PALKIN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2166-2181).—A continuation of previous work (E. S. R., 34, p. 502).

**Preparation of bromoacetylglucose and certain other bromoacetyl sugars,** J. K. DALE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2187, 2188).

**Condensation of thiobarbituric acid with aromatic aldehydes,** A. W. DOX and G. P. PLAISANCE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2164-2166).—In the course of a study at the Iowa Experiment Station on the reaction between aromatic aldehydes and the methylene group of the ureids of malonic acid, a number of condensation products were prepared and are described.

**Concerning certain aromatic constituents of urine,** R. J. ANDERSON (*New York State Sta. Tech. Bul.* 55 (1916), pp. 3-25; *Jour. Biol. Chem.*, 26 (1916), No. 2, pp. 387-415).—This bulletin reports the following studies:

I. *The nonphenolic volatile oils of cow urinc.*—The author has shown that the so-called neutral oil obtained from cow urine consists for the greater part

of para-cresol. A very small percentage of an aromatic and nonphenolic oil of agreeable odor, having the composition  $C_{10}H_{16}O$ , was also present with the oil. This substance was found to be present in larger amounts during the summer months than during the winter, and the oils eliminated at the two seasons not to be chemically identical. It is indicated that the nature of these substances apparently depends upon the nature of the terpene-like bodies contained in the feed which the animals obtain.

The terms "urogon" and "urogol," used by Mooser,<sup>1</sup> have been shown to be identical with the mixture of para-cresol and the nonphenolic oil described.

II. *The nonphenolic volatile oils of goat urine.*—Experimental data presented show that the neutral oil obtained from goat urine which has been previously described<sup>2</sup> under the name of "urogon" is not a chemical entity but a mixture. The substances isolated are identical with the oils isolated from cow urine.

III. *The nonphenolic volatile oils of horse and human urine.*—A neutral alkali-insoluble oil which had the composition corresponding to the formula  $C_7H_{12}O$  was isolated from horse urine. An oil of similar composition and properties was found in human urine. On account of the very small yield obtained the oils could not be identified. It is deemed probable that "the kind of neutral alkali-insoluble oils excreted in the urine of different animals will be found to depend to a large extent upon the nature of the terpene-like bodies contained in the food, and for this reason the nature of the oil will vary in accordance with season and the available food supply."

**The chemistry of the vitamins, R. R. WILLIAMS** (*Philippine Jour. Sci., Sect. A, 11 (1916), No. 2, pp. 49-57*).—The author describes a method for separating the vitamin of rice polishings and reports the preparation of several derivatives of nicotinic acid, the curative property of these derivatives being tested by feeding per os to neuritic fowls.

**The chemical nature of the "vitamins".—II, Isomerism in natural antineuritic substances, R. R. WILLIAMS and A. SEIDELL** (*Jour. Biol. Chem., 26 (1916), No. 2, pp. 431-456, pl. 1, figs. 5*).—Continuing the work previously noted (*E. S. R., 35, p. 711*), the authors have found that the physiological properties of autolyzed yeast are not appreciably altered by treatment with relatively concentrated caustic alkali. Aqueous alkali in contact with fullers' earth "activated" by contact with autolyzed yeast filtrate modified the physiological action of the yeast filtrate in respect to its power to maintain the weight of pigeons on a deficient diet, but did not sensibly affect its antineuritic function.

A crystalline antineuritic substance was obtained by alkaline extraction of "activated" fullers' earth, the physiological action of which was apparently not due to adhering mother liquor. Attempts to purify this substance by recrystallization resulted in a loss of its antineuritic properties. The resulting product was found to be identical with adenin, and by suitable treatment again acquired antineuritic properties. From the results thus obtained it is deemed probable that an isomer of adenin is the chemical entity responsible for the characteristic physiological properties of the vitamin investigated.

The experimental data are described in detail and the chemical nature of the vitamins discussed. In connection with the latter it is suggested that "the vitamins contain one or more groups of atoms constituting nuclei in which the physiological properties are resident. In a free state these nuclei possess the vitamin activity, but under ordinary conditions are spontaneously transformed into isomers which do not possess antineuritic power. The complementary substances or substituent groups with which these nuclei are more or less firmly

<sup>1</sup> Hoppe-Seyler's Ztschr. Physiol. Chem., 63 (1909), No. 2-3, pp. 155-200.

<sup>2</sup> Pfüger's Arch. Physiol., 156 (1914), pp. 225-252.

combined in nature exert a stabilizing and perhaps otherwise favorable influence on the curative nucleus, but do not in themselves possess the vitamin type of physiological potency. Accordingly it is believed that while partial cleavage of vitamins may result only in a modification of their physiological properties, by certain means disruption may go so far as to effect a complete separation of 'nucleus' and 'stabilizer,' and if it does so will be followed by loss of curative power due to isomerization."

The terminology introduced by McCollum and Kennedy (E. S. R., 35, p. 166), based on the solubility of the substances isolated, is considered by the authors to be an unfortunate choice because of the influence of various other substances on solubility, and in their discussion they retain the word vitamin, as employed by Funk.

On the products of the action of certain amylases upon soluble starch, with special reference to the formation of glucose, H. C. SHERMAN and P. W. PUNNETT (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 9, pp. 1877-1885).—Experiments are described from which it is concluded that any of the amylases tested (pancreatic, malt, and taka-diastrase) may form some glucose. Under the conditions which prevail in the usual determinations of diastatic power, however, the yield of maltose so far predominates as to justify the custom of calculating the reducing powers of the digestion products as due to maltose alone.

Experiments upon starch as substrate for enzym action, H. C. SHERMAN and J. C. BAKER (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 9, pp. 1885-1904).—"Dispersions of commercial potato starch in water or of purified potato starch in water containing a small amount of electrolyte (sodium chlorid) have been separated by centrifugal force into a heavier, very viscous, opalescent layer containing the more abundant, less soluble component of the starch (Meyer's  $\alpha$ -amylose, Maquenne's amylopectin), and a lighter, limpid solution containing the less abundant, more soluble component (Meyer's  $\beta$ -amylose, Maquenne's amylose)."

It is indicated that the centrifugal method described for the separation of the starch components does not completely separate either component from the other, but affords a means of approximate separation in which the danger of contamination, denaturization, or retrogradation is minimized. The method is well adapted to the study of the effects of the different amylases.

"Pancreatic amylase both in commercial and in highly purified form produced reducing sugar more rapidly from  $\beta$ -amylose than from  $\alpha$ -amylose, autoclaved starch, or Lintner soluble starch, the last three giving very similar results when used as substrate for this enzyme. Not only does the  $\beta$ -amylose substrate show a larger yield of maltose at each of the various time intervals tested, but the initial speed of hydrolysis is better maintained with this substrate than with either of the others.

"Purified malt amylase shows in the earlier stages of its action a somewhat greater yield of maltose from  $\alpha$ - than from  $\beta$ -amylose. As the digestion proceeds the saccharogenic action of this enzyme upon  $\alpha$ -amylose becomes slower, while its action upon  $\beta$ -amylose is well sustained, so that in cases in which the hydrolysis proceeds to the production of more than half the theoretical yield of maltose the final result shows a greater saccharogenic action upon  $\beta$ - than upon  $\alpha$ -amylose. The results obtained upon autoclaved starch and Lintner soluble starch are very similar to those found with  $\alpha$ -amylose."

Taka-diastrase was found to digest Lintner soluble starch, autoclaved whole starch, and  $\alpha$ -amylose at about equal rates, and  $\beta$ -amylose at a somewhat higher rate. The action of pancreatic or malt amylase is better sustained than that of taka-diastrase upon the  $\beta$ -amylose substrate. "This relatively early falling off

in the speed of sugar formation, together with the high ratio of amyloclastic to saccharogenic power, indicate that this amylase is a more active catalyst of the earlier than of the later stages of the hydrolysis."

The data submitted indicate that "Lintner soluble starch is well adapted to its purpose as substrate for testing the activities of the different amylases, and that its use leads to conservative estimates of the diastatic powers of purified preparations."

**An examination of certain methods for the study of proteolytic action,** H. C. SHERMAN and DORA E. NEUN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2199-2216, figs. 4).—The Mett method for determination of total nitrogen of digestion products, the measurement of the increase of amino nitrogen by the Van Slyke method, the titration of the acidity of digestion products, the increase of electrical conductivity, the polariscopic method, and the biuret and ninhydrin reactions for determining the proteolytic activity were studied in detail. The experimental results are submitted in tabular form.

It is indicated that in general the quantitative determination of the total nitrogen or the amino nitrogen of the digestion products appears to be more delicate as a means of detecting proteolysis than either the biuret or the ninhydrin reaction, and more delicate, accurate, and generally applicable than any of the other quantitative methods studied. "The results emphasize the importance, in quantitative comparisons, of so limiting the amount of enzym preparation and the time of its action as to keep within the region in which the velocity of hydrolysis is directly proportional to the enzym concentration."

**Nitrogen determinations by direct nesslerization,** O. FOLIN and W. DENIS (*Jour. Biol. Chem.*, 26 (1916), No. 2, pp. 473-506).—Five papers are presented.

I. *Total nitrogen in urine* (pp. 473-489).—A colorimetric procedure is described in detail. For the digestion of the sample a mixture of phosphoric and sulphuric acids (3:1) is recommended on account of its markedly reducing the amount of sulphate in the digested material and thus obviating the possible precipitation of the colored mercury ammonium compound in the color comparison.

Comparative analytical data with the standard Kjeldahl method indicate the accuracy of the micro-procedure.

Notes on the destructive digestion of urine, Nessler's reagent, the neutralization and dilution of the digestion mixture, standard ammonium sulphate solutions, the use of Ostwald pipettes, and the use of the colorimeter are included.

II. *Nonprotein nitrogen in blood* (pp. 491-496).—Metaphosphoric acid (so-called "glacial" phosphoric acid) has been found to be an excellent protein precipitant. It is indicated as being better than colloidal iron and fully as good as trichloroacetic acid.

The determination of nonprotein nitrogen is described as follows: To 20 cc. of water in a 50-cc. volumetric flask 5 cc. of blood is added, and then 3 cc. of a 25 per cent metaphosphoric acid. The liquid is thoroughly mixed and allowed to stand for from 1 to 24 hours, after which the flask is filled to the mark, thoroughly agitated, and the contents filtered through a dry filter. It is important that the mixture be allowed to stand for a sufficient time before filtration. An aliquot, corresponding to 1 cc. of blood, of the perfectly clear and colorless filtrate is used for determining the nitrogen, the procedure being essentially the same as that used in urine samples.

III. *Ammonia in urine* (pp. 497-499).—A procedure in which blood charcoal (ammonia-free) is used to remove the creatinin and other reducing substances found in urine, so that the nesslerized filtrates remain clear for several hours, is described. A small amount of metaphosphoric acid is added to insure the

presence of all the ammonia as salts, since the free ammonia is absorbed by charcoal. Analytical data submitted indicate that the new procedure is absolutely reliable.

IV. *Urea in urine* (501-503).—In the procedure described the urea is decomposed in the usual manner by urease, and after removal of the urease materials with metaphosphoric acid and treatment with blood charcoal the filtrate is nesslerized and the ammonia determined as usual. Comparative analytical data submitted indicate the accuracy of the procedure.

V. *Urea in blood* (pp. 505, 506).—The method described is essentially the same as that used in the determination of urea in urine.

Estimation of calcium in ash of forage plants and animal carcasses, S. B. KUZIRIAN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 1996-2000).—A rapid and accurate modified procedure is described by the author, at the Iowa Experiment Station, which consists essentially in removing the phosphorus as phosphomolybdate from an acid solution of the ash and precipitation of the calcium from the filtrate as calcium oxalate, either directly or after the removal of the excess of molybdenum as sulphid. No advantage was found, however, in the latter process.

Advantages claimed for the procedure as compared to the official basic acetate method (E. S. R., 20, p. 512) are that it yields more accurate and concordant results; no attention need be given to the maintenance of exact neutrality of the solution; the volume of the filtrate resulting from the precipitation of phosphorus can be kept reasonably small, so that no evaporation is necessary; the time required for the determination is greatly shortened; and phosphorus and calcium may be determined in the same aliquot.

The method outlined by Shedd (E. S. R., 27, p. 616) has been found to yield excellent results with slight modifications, which consist essentially in boiling the calcium oxalate precipitate for 30 minutes on a hot plate, filtering through a Gooch crucible, and igniting to convert the oxalates into oxids instead of dissolving the precipitate with hydrochloric acid and reprecipitating with dilute ammonia, which operation seems to be insufficient to remove completely adhering traces of molybdenum. The ignited residue is then dissolved in dilute hydrochloric acid, filtered, ammonium chlorid and ammonia added, and the liquid boiled until the odor of ammonia is faint. The precipitated iron and aluminum are removed and the calcium precipitated as oxalate.

Modification of the Pratt method for the determination of citric acid, J. J. WILLAMAN (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2193-2199).—After a thorough study of the various steps in the method described by Pratt (E. S. R., 26, p. 509) the following modified method is outlined:

The pectins in the fruit juice or other plant material are precipitated by two volumes of 50 per cent alcohol, and the precipitate, after settling, filtered through filter paper on a Büchner funnel and washed twice with 65 per cent alcohol. The filtrate is diluted with water to give approximately a 30 per cent alcohol content by volume, and 5 cc. of barium acetate solution then added. The barium citrate is filtered through asbestos in a Gooch crucible, washed with 30 per cent alcohol, and dried in a water oven. The precipitate is dissolved in hot 6 per cent phosphoric acid solution, using three portions of 20 cc. each and followed by hot water. The filtrate and washings (which should be about 100 cc. in volume) are transferred to the oxidation flask, a piece of glass tubing or glass beads added, if necessary, to prevent bumping, and the solution oxidized with potassium permanganate as described in the original method. The adapter of the condenser dips into 40 cc. of Denigés' solution contained in a 500 cc. Erlenmeyer flask. After the oxidation is com-

plete the distillate is made up to about 300 cc. volume, put under a reflux condenser, and boiled gently for 45 minutes. The precipitate is then filtered hot through paper, washed by decantation twice with hot water, and dissolved in two or three small portions of 5 per cent hydrochloric acid by heating. The acid solution is, after cooling, neutralized with 10 per cent sodium hydroxid, and made up to 100 cc. volume.

The whole or an aliquot of the mercury solution can be titrated against standard potassium iodid solution, or the mercuric chlorid solution can be used in a burette and titrated against standard potassium iodid. A determination factor giving the citric acid equivalent of cubic centimeters of potassium iodid is included. Malic, tartaric (except quantities of 5 gm. or over), oxalic, and aconitic acids do not interfere with the determination. The presence of large amounts of sugar or other substances capable of reducing permanganate tends to yield slightly high results, but the difference is inconsiderable.

Analytical data are submitted which indicate that the modified method, if followed rigidly, will give much more satisfactory results than the original procedure.

**A comparison of barbituric acid, thiobarbituric acid, and malonylguanidin as quantitative precipitants for furfural, A. W. DOX and G. P. PLAISANCE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 10, pp. 2156-2164).**—Experimental data submitted by the authors from the Iowa Experiment Station demonstrate that thiobarbituric acid condenses readily with furfural in 12 per cent hydrochloric acid solution, and forms, by the elimination of one molecule of water, a definite compound to which a definite chemical formula can be ascribed. The reaction is quantitative, yielding a voluminous precipitate which can be filtered, dried, and weighed. Thiobarbituric acid is indicated as being superior to phloroglucinol as a precipitant for furfural, and no correction for solubility of the product is necessary. It is also preferable to barbituric acid, for the reason that the reaction is quantitative with as small amounts of furfural as 12 mg., and a large excess of precipitant is unnecessary, thus avoiding possible errors due to inclusion. The precipitant has a further advantage in that the percentages of nitrogen and sulphur can be easily determined in cases where doubt might exist as to the purity of the product in case homologues of furfural were present.

It is suggested that thiobarbituric acid, which can be prepared in a pure state with little difficulty, may be found useful in the analysis of agricultural products, in place of phloroglucinol or barbituric acid, for the determination of pentoses and pentosans.

**Methods in soil analysis, F. E. BEAR and R. M. SALTER (*West Virginia Sta. Bul.* 159 (1916), pp. 3-24, figs. 2).**—This bulletin outlines in detail methods for complete soil analysis which have been found reliable by their successful use in several hundred analyses of various types of West Virginia soils.

**The estimation of thiosulphate sulphur in lime-sulphur solutions by iodine titration, P. L. BLUMENTHAL and S. D. AVERITT (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 9, pp. 1701-1704).**—From a study carried on at the Kentucky Experiment Station, the authors conclude that "an excess of iodine does react with tetrathionate in neutral or faintly acid solutions upon standing. In every iodine titration on a lime-sulphur solution a small quantity of sulphate is formed; in some lime-sulphur solutions this is the only sulphate found.

"The quantity of iodine used to form sulphate in an ordinary titration does not cause an appreciable error in the determination of thiosulphate. The iodine value obtained after decomposing polysulphids by HCl titration actually represents thiosulphate, since the barium sulphate obtained from such solutions

after oxidation agrees very closely with the titration values. The presence of sulphites, which would also be titrated at this point, would tend to cause high results for thiosulphate as calculated from the iodine value. If anything, the gravimetric results for thiosulphate are a trifle higher than the titration values, which point to an absence of sulphites, although this in itself is not absolute proof of the fact."

See also a previous note by Averitt (E. S. R., 36, p. 16).

[Report of the chemical division], C. H. WRIGHT (*Fiji Dept. Agr. Ann. Rpt. 1915, pp. 22-26*).—These pages report brief notes on soil analysis, physical and chemical constants of lemon grass oil distilled under varying conditions, and the examination of bat guanos, limes and coral sand, mustard oil, coconut products, lemons, and miscellaneous materials.

Experiments on the conservation of fruits and vegetables by desiccation, V. VALVASSORI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 13 (1916), No. 2, pp. 56-64, fig. 1*).—This article briefly describes some experiments obtained in a study of fruit and vegetable conservation by desiccation with heat, and indicates the great economic importance of the industry. A table giving the time necessary for sterilization, optimum temperatures and time necessary for desiccation, and yield of finished product from 100 kg. of fresh material of a number of vegetables is included.

Instructions for processing fruits and vegetables for exhibition only, J. H. PAGE (*Bur. Mines, Manfrs. and Agr. [Ark.], Bul. 4 (1916), pp. 15*).—This bulletin briefly describes procedures and gives formulas for preserving fruits and vegetables for exhibition purposes.

Report on vegetable dyestuffs, F. MARSDEN (*Mysore Econ. Conf. [India], Indus. and Com. Committee Bul. 31 (1916), pp. VII+15*).—This is the report of the work carried out by the dyeing expert to the Government of Madras in connection with the utilization of indigenous or other materials in the dyeing industry. An introduction by A. Chatterton, director of industries and commerce in Mysore, is included.

From the results of the investigation it is concluded that the indigenous materials are incapable of meeting the demands which have been created by the development of the manufacture of synthetic colors.

## SOILS—FERTILIZERS.

Measurement of the surface forces in soils, C. A. SHULL (*Bot. Gaz., 62 (1916), No. 1, pp. 1-31, figs. 5*).—Experiments conducted at the universities of Kansas and Chicago on the force with which particles of soils of varying fineness retain moisture at different degrees of dryness and to devise a method for measuring this force are reported. The soils used were heavy silt clay, fine quartz sand, loam, very fine sandy loam, sand, and fine sand.

The seeds of *Xanthium pennsylvanicum* were used to measure the moisture-holding powers of the soils by firmly packing dry seeds of known weight in a soil of known moisture content and allowing the forces tending to move the moisture to reach equilibrium. The force with which these seeds absorb water was first determined by the use of osmotic solutions and by the vapor pressure equilibrium method, the former being found the more reliable. The air-dried seeds showed an initial attraction for water of nearly 1,000 atmospheres, and it was found that the attraction which exists at any moisture content between saturation and air dryness can be approximated.

In the experiments with soils it was found that the air-dry subsoil of the silt loam held its hygroscopic moisture with about the same force as an air-dry

seed; that is, about 1,000 atmospheres. As the moisture content of the soil increased the surface force decreased rapidly. When about 3.5 per cent of water was added to the air-dry soil, the force remaining was about 375 atmospheres. When the moisture content reached 6 per cent above air-dry in this soil it was held with a force of 130 or more atmospheres. At 11 per cent above air-dry the holding power fell to 22.4 atmospheres. At the wilting coefficient of the soil (13.3 per cent above air-dry in the silt loam subsoil) the "back pull" of the soil particles amounted to not more than that of a 0.1 molecular volume sodium chlorid solution; that is, not more than about 4 atmospheres. This was shown to hold true for a number of types of soil with widely varying wilting coefficients.

"The wilting of plants at the wilting coefficient of the soil can not be due to lack of moisture in the soil, nor to lack of a gradient of forces tending to move water toward the plant. The view is held, therefore, that the wilting at this critical soil moisture content must be due to the increasing slowness of water movement from soil particle to soil particle, and from these to the root hairs, the rate of movement falling below that necessary to maintain turgidity of the cells of the aerial parts even under conditions of low transpiration."

Thirty-six references to literature bearing on the subject are also cited.

Use of two indirect methods for the determination of the hygroscopic coefficients of soils, F. J. ALWAY and V. L. CLARK (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 8, pp. 345-359, fig. 1).—Experiments conducted at the Nebraska Experiment Station on the determination of the hygroscopic coefficients of a number of Nebraska soils from their maximum water capacities and their contents of hygroscopic moisture are reported.

It was found that while the Briggs-Shantz formula, hygroscopic coefficient = (maximum water capacity - 21) × 0.234 (E. S. R., 26, p. 628), "with many soils gives values fully in accord with those directly determined, with many others it gives results so widely divergent that it can not be regarded as sufficiently reliable for studies of available soil moisture, or even for soil-survey purposes."

The studies of the relation between hygroscopic coefficient and hygroscopic moisture showed "that the hygroscopic coefficient may be calculated from the hygroscopic moisture found in a soil which has been allowed to come into equilibrium with an only partially saturated atmosphere, and that this method will require only simple equipment, a minimum of skill on the part of the operator, and be so economical of time as to recommend it wherever a very large number of samples have to be dealt with."

Note on soil denudation by rainfall and drainage: Conservation of soil moisture. G. D. HOPE (*Agr. Jour. India*, 11 (1916), No. 2, pp. 134-141, pls. 4).—Suggestions for the prevention of erosion of northeast Indian tea soils are given, special reference being made to terracing and drainage as practiced on Java tea soils.

Soil aeration in agriculture, A. HOWARD (*Agr. Research Inst. Pusa Bul.* 61 (1916), pp. 22, pls. 2, figs. 3).—This is a lecture delivered at the meeting of the Board of Agriculture at Pusa, India, on soil ventilation in its physiological relation to crop production, including some practical applications of soil aeration by means of drainage, irrigation, and manuring.

The toxicity of bog water, G. B. RIGG (*Amer. Jour. Bot.*, 3 (1916), No. 8, pp. 436, 437).—Experiments made at the University of Washington with waters drawn from sphagnum bogs of the Puget Sound region and Alaska are reported.

It is reported that "(1) when they were filtered through filter paper, then saturated with NaCl, MgSO<sub>4</sub>, Na<sub>2</sub>HPO<sub>4</sub>, or (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, and allowed to stand

over night, the samples tested have all shown a precipitate. (2) When this precipitate was filtered off and the filtrate dialyzed in a dialyzing tube in running water until it no longer showed a precipitate with  $\text{BaCl}_2$ , the filtrate did not prove toxic to root hairs on *Tradescantia* cuttings placed in it, while controls in bog water allowed only a very poor development of root hairs on cuttings of this species. (3) When 500 cc. of filtered bog water was distilled until the residue was only 80 cc., the distillate was colorless and was not toxic to root hairs on *Tradescantia* cuttings while the residue was much darker in color than bog water and almost entirely inhibited the formation of root hairs on these cuttings. (4) When saturated with  $(\text{NH}_4)_2\text{SO}_4$  and allowed to stand over night, the above distillate gave no precipitate, while the residue gave a much heavier precipitate than untreated bog water did. (5) All samples of bog water tested were acid to litmus and to phenolphthalein. (6) The acidity of the residue mentioned in (3) was greater than that of the untreated bog water, while the acidity of the distillate was less than that of the untreated bog water. The acidity was determined by neutralization with N/20 NaOH, using phenolphthalein as an indicator. . . . The fact that the osmotic pressure of bog water is very low suggests that the material in solution in it is probably in a colloidal state. The data here given seem to confirm this view and to warrant the suggestion that this colloidal matter is a large factor in the toxicity of the water."

A list of ten references to literature bearing on the subject is appended.

**Some factors influencing nitrogen fixation and nitrification, B. WILLIAMS** (*Bot. Gaz.*, 62 (1916), No. 4, pp. 311-317).—In continuation of work previously reported (*E. S. R.*, 33, p. 620), experiments conducted at the Virginia Experiment Station on nitrogen fixation in garden soil and in various other soils stored in the laboratory for periods of different lengths showed that the nitrogen-fixing flora significantly decreased in its activity under the influence of drying. This deterioration was manifested as early as two weeks after removing the soil from the field and exposing it to the ordinary laboratory conditions of drying. After 15 months, however, a number of soils retained an ability to fix nitrogen, which is taken to indicate that some species at least have considerable resistance to drying. A number of qualitative tests for Azotobacter in soils kept in storage for 15 months indicated that this organism is more easily attenuated than some other species. Further tests with three soils with low powers of fixation showed that the soil extract itself "probably does not carry substances which would retard fixation."

A continuation of studies on nitrification in soils of poor nitrifying power to which sugar and lime were added showed that without the use of lime a number of soils completely failed to nitrify ammonium sulphate, and few exhibited what might be termed an average nitrifying power. Under the influence of lime there was an increase of nitrifying power in the majority of the soils, although the stimulation was not especially noteworthy. "It appears that where there is some development of the nitrifying flora in the soil originally the effects of lime are decidedly more evident than in those soils apparently devoid of nitrifying power."

There was no formation of nitrates whatever under the influence of 2 per cent of mannite. It not only failed to afford a source of energy for the nitrifying ferments, but exerted a depressing effect on the activities of such as were present.

**Production of alkali in soils by denitrification, R. ALADJEM** (*Cairo Sci. Jour.*, 8 (1914), No. 99, pp. 274-278).—Studies on the processes of nitrification and denitrification in sandy loam soil and the conditions governing them are reported.

It was found that when nitrification takes place in soil which contains even traces of sodium, potassium, and calcium, the corresponding nitrates are formed which—when conditions favorable to denitrification, such as water-logging, are produced—are decomposed, giving rise to alkaline bicarbonates. It was found that such denitrification takes place only when the soil is so saturated with water as to be completely deprived of air. The alkaline bicarbonates formed are capable under certain conditions of being transformed into carbonates.

Further observations on protozoa in relation to soil bacteria, T. GOODEY (*Proc. Roy. Soc. [London], Ser. B, 89 (1916), No. B 616, pp. 297-314, figs. 5; abs. in Jour. Soc. Chem. Indus., 35 (1916), No. 17, p. 936*).—In continuation and extension of work previously reported (*E. S. R., 33, p. 515*) on the inoculation of protozoa into soil, experiments are reported with a fibrous loam soil representing an attempt to eliminate the source of error of the previous experiments occasioned by introducing large numbers of bacteria into the soil along with the added protozoa. The aim was to inoculate a partially sterilized soil with protozoa freed from bacteria. A method is described whereby protozoa were successfully separated from large numbers of bacteria and used for mass inoculation of a treated soil.

It was concluded from the results obtained that "protozoa, especially amoeba of the *limax* group and other larger forms, can lead an active existence and multiply in soil and exert a depressing effect on bacterial numbers." It is considered probable that for a given soil a certain point must be reached in protozoal numbers before the depression in bacterial numbers is caused. In the soil under investigation this number appeared to be approximately 30,000 *Amoeba limax* per gram. It appeared to be necessary to add the protozoa to a treated soil in a small quantity of untreated soil to insure their having a suitable medium in which to grow and multiply. It did not appear possible to carry out mass inoculations of protozoa into treated soil in such a way that they come into action and limit bacterial activity, and the explanation advanced to account for this failure is that the treated soil alone affords an unsuitable medium for the active trophic existence of protozoa.

Soils of the Sabak district on the Bernam River, J. GRANTHAM (*Agr. Bul. Fed. Malay States, 4 (1916), No. 9, pp. 298-300*).—Mechanical and chemical analyses of 13 samples of coconut and jungle soils are reported and discussed. The soils of the district are all of the heavy clay type of medium acidity and of alluvial origin, with the clay portion varying from about 20 to over 40 per cent, the higher percentage preponderating. They contain a fair percentage of organic matter and are characterized by being unusually rich in potash and nitrogen. The phosphate content, while rather low, is said to be above the average for the country.

Investigation of the peat bogs and peat industry of Canada, 1913-14, A. ANREP (*Canada Dept. Mines, Mines Branch Bul. 11 (1915), pp. XII+185, pls. 122, figs. 66*).—Particulars are given of the detailed examination of peat bogs in the Provinces of Ontario, Quebec, Prince Edward Island, and Nova Scotia. In addition are included over 60 photographic illustrations of plants found in and composing the bogs investigated, and a number of translations of official documents on the utilization of peat, dealing with recent developments in European practice.

The analysis of soils, L. J. WILD (*Jour. Canterbury Agr. and Past. Assoc., 3, ser., 4 (1916), pp. 35-41*).—A brief discussion of the numerous factors upon which the fertility and productiveness of a given soil depends is given in order to show the impracticability of attempting to judge a soil on the basis of analytical data only.

Bureau of Soils, U. S. Department of Agriculture, M. WHITNEY (*Cornell Countryman*, 14 (1916), No. 1, pp. 18-22, figs. 2).—This is a brief outline of the chief activities of the Bureau of Soils.

Artificial manures, 1916 (*Glamorgan County Council, Agr. Committee [Pamphlet]*, 1916, pp. 4).—Brief suggestions on manures and manuring to meet war-time conditions in England are given.

Soil fertility considerations in the feeding of hogs and milch cows, E. B. FORBES (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 11, pp. 351, 352).—In a series of income and outgo experiments with five growing hogs, it was found that on the average the excreta contained 74, 87, and 86 per cent of the nitrogen, phosphorus, and potassium of the rations fed. In two series of experiments with six cows in each, it was found that the excreta contained 67.45, 74.4, and 71.6 per cent of the nitrogen, potassium, and phosphorus, respectively, of the rations fed, being in all cases appreciably less than the percentages found in the excreta of the growing hogs.

Plant food deficiencies of Coastal Plain and Piedmont soils, C. B. WILLIAMS (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 823, 824; *Proc. Soc. Prom. Agr. Sci.*, 36 (1915), pp. 67-75).—Data showing the average amounts of nitrogen, phosphoric acid, and potash in the leading soil types of the Coastal Plain and Piedmont regions in which field work has been conducted by the North Carolina Experiment Station are reported, which indicate that "potentially most of the soils are fairly well supplied with potash, but that the amounts of phosphoric acid and nitrogen, one or the other, or both, are at present or soon will be limiting factors in the production of large crops." Data obtained in field fertilizer experiments by the station are taken to indicate that the "chief needs for plant growth in the Coastal Plain region are generally first for nitrogen, and second for potash and lime. Those soils of chief importance and extent in the Piedmont region show a lack first for phosphoric acid, and second for nitrogen. Without the addition of these deficient plant food constituents, it will be impossible to grow large crops for any great length of time."

Note on the soil of the experimental farms [in Burma], F. J. WARTH (*Dept. Agr. Burma Bul.* 13 (1913), pp. 9).—Pot culture experiments on alkaline heavy clay and clay, neutral clay loam, sand and sandy loam, slightly acid sand and sandy loam, and strongly acid clay paddy soils are reported, together with chemical analyses of the different soils, the purpose being to throw light on the problem of availability of phosphoric acid in paddy soils.

It was found that with the soils used citric acid extraction forms no criterion for the amount of phosphoric acid available for a paddy crop. Pot cultures showed that a shortage of phosphoric acid was felt at a very early stage. This shortage in the case of a long-lived variety grown under favorable conditions is in time more or less made up as the plant develops. The normal yields of paddy from the four heavy soils were least, and these soils also were deficient in phosphoric acid. "The figures for total and available phosphoric acid given in the soil analysis . . . are undoubtedly an index of the total supply of this substance and its state of occurrence."

Fertilizer experiments with sugar cane on the red clay soil, P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt.* 1915, pp. 16-24).—In continuation of investigations previously noted (*E. S. R.*, 30, p. 818) experiments to determine the fertilizer requirements of areas found to respond to fertilizers in the previous work are reported.

The results of four experiments on the effect of fertilizers on sugar cane on the lowland red clay soil, involving 290 plats and 58 acres of land, showed that one field failed to respond to 3,500 lbs. of quicklime per acre with and without

various commercial fertilizers. On another field all combinations of nitrogen, phosphoric acid, and potash applied at the rate of 50 lbs. of each element per acre were ineffective. On two other fields fertilizers measurably increased the yield. Where the land responded to fertilizers nitrogen was the only essential element. A single test with plant cane showed that, calling the effectiveness of ammonium sulphate 100, that of sodium nitrate was 100, that of tankage 111, and that of cyanamid 134.

The residual effects of fertilizers, F. E. BEAR, R. M. SALTER ET AL. (*West Virginia Sta. Bul. 160 (1916), pp. 3-26, figs. 2*).—Analyses of samples of the soil of fertilizer plats which have been under experiment for 15 years at the station (E. S. R., 35, p. 22) are reported to show the effects on the soil of different fertilizer treatments and of the crops produced.

It was found that there was a gain in nitrogen averaging 20 lbs. per acre per year on the plat receiving acid phosphate. On the plat on which acid phosphate and sulphate of potash were applied the gain in nitrogen amounted to 78 lbs. per acre per year. The phosphorus applied to the soil in excess of the needs of the crops was not lost in the drainage water, but was fixed in the surface  $6\frac{3}{8}$  in. of soil. Organic matter was maintained and increased by the use of fertilizers without plowing under green manuring crops or crop residues other than the stubble left behind after the crops were harvested. The use of quicklime in excess of the needs of the soil caused a loss of nitrogen, phosphorus, and organic matter from the surface soil considerably larger than the increased yields produced would justify. The use of manure or fertilizers (with the exception of sulphate of potash) had a tendency to decrease the acidity of the soil.

[Experiments in Java with green manures], W. M. VAN HELTEN (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Cultuurtuin, No. 2 (1915), pp. 32, pls. 4; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, p. 198*).—The author describes a number of plants (among others, *Tephrosia candida*, *T. hookeriana* var. *amœna*, and *T. vogelii*; *Centrosema plumieri*; *Clitoria cajanifolia*; *Desmodium gyroides*; *Indigofera hirsuta* and *I. sumatrana*; and *Crotalaria striata*) which gave good results when used as green manure in the experiment garden at Buitenzorg, especially after the alang alang (*Imperata* sp.) and weeds had been previously uprooted.

Experiments carried out at the experiment garden and in plantations of Java showed that "*T. candida* gave better results than the other plants used as green manure, especially in the Hevea, cacao, and tea plantations. *Clitoria cajanifolia* can be recommended as preventing erosion on sloping ground. *Cassia pumila* rapidly covers the ground and produces abundant foliage. It is to be recommended for young plantations of rubber trees and of tea shrubs in order to prevent erosion and the spread of weeds. *Cassia tora* has a subfrutescent habit and grows as well on the seaboard as in the mountains."

The author advises that the experiments be continued with *Tephrosia* sp., *Crotalaria muyussi*, *D. hirsutum*, and *I. villosa* by manuring crops other than those growing in the Buitenzorg experiment garden.

Loss of organic matter in green manuring, G. E. BOLTZ (*Mo. Bul. Ohio Sta., 1 (1916), No. 11, pp. 347-350*).—Plat and lysimeter experiments are described, in which green clover was added to the soil at rates of 7,744 and 17,520 lbs. per acre, being plowed under in two cases and left on the surface in two cases.

It was concluded that an accumulation of a large amount of organic matter does not take place as rapidly as is often assumed. "The loss of organic matter from a crop of clover which is cut and allowed to remain on the surface of soil for 206 days is practically the same as the loss of organic matter by

feeding." It is further concluded that organic matter is not lost so rapidly and more accumulates in the soil when it is incorporated in the soil than when applied to the surface.

**The utilization of the nitrogen of manure in relation to the time of manuring the soil,** A. SABASHNIKOV (*Selsk. Khoz. i L'vsov.*, 249 (1915), Dec., pp. 499-512).—The general question of the utilization of manure nitrogen by crops is discussed, and 11 years of experiments with rye and 4 years of experiments with wheat are reported which showed that larger increases in the rye crop were obtained when manure was plowed under in June than when plowed under in May. The opposite was the case with wheat. A decrease in the rye crop and the smallest increases in the wheat crop resulted from plowing under manure in April. It was further found that in years in which the summer and autumn were rainy and the rye grew thickly and was beaten down the following spring by wind or rain, manure lowered the yields.

**Bat guanos,** P. L. GILE and J. O. CARRERO (*Porto Rico Sta. Rpt. 1915*, pp. 13, 14).—On the basis of the results of analyses of 200 samples of bat guanos for nitrogen and phosphoric acid and experiments on the availability of the phosphoric acid of the guanos as compared with acid phosphate, bone meal, and basic slag it is stated that "the greater part of the guanos are to be considered as low-grade phosphatic fertilizers." The total phosphoric acid is very variable, ranging in the samples analyzed from 1 to 42 per cent.

"By vegetation tests it appears that if the availability of the phosphoric acid in acid phosphate is taken as 100 per cent, the effectiveness of the phosphoric acid in different guanos ranges from zero to 100 per cent. With most guanos the solubility of the phosphoric acid in neutral ammonium citrate parallels very closely its availability as determined by vegetation tests with corn and millet. As phosphatic fertilizers the guanos are equally effective for corn and millet. Most of the deposits contain but little nitrogen, although there is a small amount of material in nearly every cave, generally the first 2 to 3 in. of the deposits, that contains considerable nitrogen. The very fresh material that has undergone no decomposition may contain 10 to 11 per cent of nitrogen."

**The availability of nitrogen in garbage tankage,** J. P. SCHROEDER (*Amer. Fert.*, 45 (1916), No. 8, pp. 21-23).—The results of pot culture tests on the availability of the nitrogen of garbage tankage are briefly compared with those obtained by the alkaline permanganate method. The conclusion is drawn "that a higher availability should be accorded the nitrogen in garbage tankage than that indicated by the permanganate methods."

**Potash in Salduro salt deposit,** H. S. GALE (*Engin. and Min. Jour.*, 102 (1916), No. 18, pp. 780-782).—A brief description of the Salduro salt deposit on the western border of Utah is given, together with analyses of the salts and the brine from the Salduro salt marsh. The deposit covers an area of over 100 square miles and varies in thickness from 3 to 5 ft. The brine analyses show a potassium content of from 2.85 to 4 per cent of the dissolved salts or from 0.76 to 1.03 per cent of the original solution, which is said to be about half the potassium content of the Searles Lake brine and twice that of the Great Salt Lake water.

**Action of calcium carbonate on acid phosphate,** E. W. MAGRUDER (*Amer. Fert.*, 45 (1916), No. 8, pp. 30-32).—Further experiments, similar to those reported by Brackett and Freeman (*E. S. R.*, 34, p. 26) on the effect of mixing calcium carbonate in the shape of ground oyster shells with acid phosphate a month old and acid phosphate only a few days old, are reported.

It was found that new acid phosphate was acted on more readily by the oyster shells than the older acid phosphate, the reaction beginning at once and

increasing with time and the amount of oyster shells used. With 30 and 50 per cent of oyster shells virtually all the water-soluble phosphoric acid disappeared.

**A critique of the hypothesis of the lime-magnesia ratio, I, II, C. B. LIPMAN** (*Plant World*, 19 (1916), Nos. 4, pp. 83-105; 5, pp. 119-135; *abs. in Chem. Abs.*, 10 (1916), No. 16, p. 2118).—A review of some of the more important investigations on the subject is given, leading to the conclusion "that in the first place there is little or no evidence in support of the necessity to plants for a proper lime-magnesia ratio in soils, which is specific for certain groups of plants. In the second place, when certain favorable effects are noted which appear to indicate that they follow from the adjustment of the ratio of lime to magnesia, such favorable effects can easily be explained on many other grounds which do not call at all for the introduction of the hypothesis of the lime-magnesia ratio."

**The effect of some manganese salts on ammonification and nitrification, P. E. BROWN and G. A. MINGES** (*Soil Sci.*, 2 (1916), No. 1, pp. 67-85).—Experiments conducted at the Iowa State College with clay loam soil containing 0.1732 per cent manganese on the effect of the sulphate, chlorid, and nitrate of manganese and of manganous oxid on the ammonification of dried blood and the nitrification of ammonium sulphate when added to the soil at rates varying from 0.005 gm. to 5 gm. per 100 gm. of soil (100 lbs. to 100,000 lbs. per acre) are reported.

It was found that "manganese chlorid in applications greater than 2,000 lbs. per acre depressed both ammonification and nitrification, the depression increasing as the size of the application was increased until a point was reached at which both processes ceased. With smaller amounts of the chlorid the effects on the two processes were not identical but tended in the same direction. Thus the applications of 100 and 200 lbs. per acre gave increases which were slight in the case of ammonification but quite distinct in the case of nitrification. With amounts greater than 200 lbs. per acre and less than 2,000 lbs., however, ammonification was depressed while no appreciable depression was apparent on nitrification.

"Manganese sulphate when applied to the soil at the rate of 100 lbs. per acre increased appreciably both ammonification and nitrification. In amounts greater than 100 lbs. per acre and less than 2,000 lbs., ammonification was increased but to a smaller extent than with the 100-lb. application, but with nitrification no gains or depressions were found with these amounts. In applications equal to or greater than 2,000 lbs. per acre, both nitrification and ammonification were depressed by manganese sulphate, the depression increasing with the size of the application.

"Manganese nitrate added to the soil at the rate of 500 lbs. per acre or in greater amounts depressed both ammonification and nitrification, the depression increasing as the size of the application was increased. Manganous oxid when applied to the soil at the rate of 2,000 lbs. per acre or in larger quantities depressed both ammonification and nitrification, the depression becoming greater as the size of the addition was increased."

It is concluded that "if manganese salts in small quantities increase crop yields on a soil that increase may be due in part at least to a beneficial effect on ammonification and nitrification with a consequently greater production of available plant food. On the other hand, if manganese salts when applied to the soil restrict crop growth, that restriction may be due in part to a depression of bacterial activity."

Six references to literature bearing on the subject are appended.

**Commercial fertilizers, P. L. HIBBARD** (*California Sta. Bul.* 272 (1916), pp. 47-99).—This bulletin reports the results of actual and guaranteed analyses and valuations of 467 samples of fertilizers and fertilizing materials collected

for inspection in California during the fiscal year ended June 30, 1916. A list of registered dealers and manufacturers of commercial fertilizers in the State is also given.

**Analyses of commercial fertilizers, P. H. WESSELS ET AL.** (*Rhode Island Sta. Insp. Bul.*, 1916, Oct., pp. 3-18).—This bulletin reports the results of actual and guaranteed analyses of 101 samples of fertilizers and fertilizing materials collected for inspection in Rhode Island during 1916. "The absence of potash in over one-half of the brands and the small amounts in those brands that do carry potash are noticeable features of the fertilizer situation in 1916."

### AGRICULTURAL BOTANY.

**Department of botanical research, D. T. MACDOUGAL** (*Carnegie Inst. Washington Year Book*, 14 (1915), pp. 55-106).—The groupings under which this work by numerous investigators is reported include equipment; photolysis, respiration, hydration, and growth; some special water relations of plants; environic relations; the Salton Sea and Mohave Desert regions; genetics; and various special investigations.

Some of the important results of this work considered as a whole are summarized by stating that plant growth takes place at the expense of definite or formative compounds, which are formed locally at a rate depending primarily upon the influence of temperature on chemical velocity. The processes may be masked or checked by imperfect respiration, enlargement depending upon conditions affecting water absorption. Light breaks down the smothering acids formed under incomplete respiration in cacti, thus facilitating the production of formative material. Lessened acidity due to light action conditions absorption of water, so that light may accelerate growth in two different ways. Auxographic instruments have been improved and glass screens of specialized transmissibility to light have been designed. The readily varying permeability of protoplasm is referred to the interrelations of the disperse phase and the disperse medium of the hydrophile emulsion colloids of which it is made up.

Sunlight is found to cause changes in air as a result of which respiration is highest on days of high solar radiation, less on cloudy days, and least at night. Arrangements are in progress for measurements of electrical conditions of the air under identical conditions. In a study of photosynthesis, formic acid has been produced from solutions of carbon dioxide and potassium carbonate, and exposure of formic acid to sunlight and ultraviolet light has produced a substance giving the reactions of a sugar and capable of use as food by green algae in darkness.

Succulent plants under desiccation may show for a long time normal proportions of water content, owing to coincident respiration or oxidation of solid materials. While the proportion of nonreducing sugars in succulent plants increased during one to six years of starvation, that of hydrolyzable carbohydrates was decreased. The starvation phenomena, some of which persist for several years after restoration of normal conditions, include hydrolysis of cell walls, deformation and peripheral thickening of nuclei, and reduction of the protoplast. Cell sap density of the desert plants is least in species native to arroyos, and shows a scale ascending through those of canyons, rocky slopes, and bajadas to those of saline areas.

Plant successions which occupy an area originally bare finally culminate in a formation the nature and permanence of which are determined by climate. The history of terrestrial vegetation shows the four great eras, Eophytic, Paleophytic, Mesophytic, and Cenophytic. The chief physical factors and their

effects corresponding to various altitudes have been evaluated. The preliminary studies of the Mohave Desert region are considered to have made such advances as to condition progress in the interpretation of the origination, phylogeny, and successions of the present vegetation of this region. Studies of the rôle of the several factors in a desert complex are thought to prove that the more divergent part of a population is eliminated by environic agencies, but that this eliminating action is subject to various modifications.

**Artificial absorption of liquids by plants through their aerial parts, C. ACQUA and VIRGINIA JACOBACCI** (*Ann. Bot. [Rome]*, 14 (1916), No. 1, pp. 33-40).—Having extended the studies previously reported by Acqua (*E. S. R.*, 35, p. 331), the authors state that solutions of glucose were absorbed by aerial portions of young white mulberry trees and produced in very small plants a conspicuous increase in growth accompanied by morphological variations both external and internal, somewhat older plants being less affected, and still more developed ones showing very slight effects from this treatment. Lupines supplied through their aerial parts with potassium nitrate or magnesium phosphate showed a retardation of growth, and those given potassium or calcium nitrate began to show decay in about 11 days, the controls remaining normal. It thus appears that some solutions of salts having nutritional value when taken up through the roots are injurious when passing directly into the plant.

**A study of physiological balance in nutrient media, J. W. SHIVE** (*Physiol. Researches*, 1 (1915), No. 7, pp. 327-397, figs. 15).—Results are given of experimental study of the growth made by plantlets of winter wheat in water cultures with respect to the physiological balance of salts and the total concentration of the medium. For each of the total concentrations employed corresponding to pressures of 0.1, 1.75, and 4 atmospheres, there were tested simultaneously 36 different proportions of the three nutrient salts calcium nitrate, magnesium sulphate, and potassium dihydrogen phosphate, a small amount of ferric phosphate being added to furnish iron. The criteria employed were total water loss by transpiration and guttation during growth, dry yield, water requirement of tops and of roots, apparent condition of tops, especially as to leaf injury, and condition of roots, especially as to lateral branching.

It is stated that within the first four weeks of growth these three salts form a nutrient medium well suited to the development of wheat plants when the total osmotic concentration is about 1.75 atmospheres and when the salts are present in either one of two somewhat similar sets of proportions which are given with discussion. These solutions are thought to be equal to any and superior to most of those of equal total concentration previously described and in general use. For a given total concentration the best physiological balance of salt proportions for tops is not the same as that for roots. The values of the cation atomic ratios magnesium:calcium, magnesium:potassium, and calcium:potassium appear to determine the growth in many cases, but this relation is not always clear for any single ratio.

Cases of injury to leaves are noted in connection with certain concentrations, also cases of root injury in connection with severe leaf injury.

Water loss during growth corresponds in a somewhat reliable way to top yields. While there appears to be no general relation between water requirement per gram of roots and total concentration for the optimal or suboptimal total concentrations, the water requirement per gram of dry tops varies in inverse order as regards the total concentration of the medium.

**Influence of certain salts and nutrient solutions on the secretion of diastase by *Penicillium camembertii*, W. J. ROBBINS** (*Amer. Jour. Bot.*, 3 (1916), No. 5, pp. 234-260, figs. 3).—The author describes a method of determining

diastatic action in solutions of soluble starch by the precipitation of the undigested starch and part of the dextrins in acid alcohol. An account is also given of the effects as to the amount of starch digested by *P. camembertii* which are produced by given concentrations of various salts. A contrast is noted between the rate of digestion of soluble starch by *P. camembertii* and *Aspergillus oryzae* and the rate observed in the case of digestion by *Mucor rouxii* or *Fusarium* sp. While no evidence was found to connect potassium and calcium with diastase formation, it is thought that nitrogen may bear an intimate relation thereto in case of *P. camembertii*.

**Nitrates in sulla** (*Heydsarum coronarium*) and other legumes, GIULIA CAMPANILE (*Ann. Bot. [Rome]*, 14 (1916), No. 1, pp. 49-75).—In the studies here outlined, employing chiefly *H. coronarium*, it was found that plants growing in a medium rich in nitrates absorbed these in a quantity somewhat larger than in ordinary soil, especially in case of the young plants. The distribution of nitrates in the plant at different periods is discussed. Data are also presented as obtained with *Lupinus albus*, these corresponding in a general way with those obtained with *Pisum sativum*, *Vicia faba*, and *V. sativa*.

**Glucosid formation by plants**, G. CIAMICIAN and C. RAVENNA (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 1, pp. 3-7).—In tests with maize and bean it was found that while pyrocatechin, gallic acid, and tannin were toxic to both these plants, saligenin was used by both, benzyl alcohol probably by bean, and hydroquinone apparently by maize. It is stated that substances resembling glucosids were formed in the young plants.

**Studies on the presence and the physiological significance of the flavone derivatives in plants, I-III**, K. SHIBATA, M. KISHIDA, and I. NAGAI (*Bot. Mag. [Tokyo]*, 29 (1915), Nos. 343, pp. 118-132, figs. 4; 347, pp. 301-308; 30 (1916), No. 352, pp. 149-178).—In the first of these papers it is claimed that the flavone derivatives, probably as glucosids, were present invariably in the epidermal cell sap, and sometimes in the deeper structures, of the aerial parts of numerous plants examined. These substances are held to be of considerable physiological importance, probably in preventing injury from ultraviolet rays.

In part II, entitled *The Chemical Biology of Alpine Plants*, further experiments and observations are reported which are considered to support the conclusions stated in the preceding article. Flavone bodies were found to be among those occurring most commonly in plants, such as chlorophyll, sugars, and starches. They appear to be related to the penetrability of atmosphere to light, probably serving to protect the plant from the short ultraviolet wave lengths, in case of plants growing in tropical or high regions, and hence accessible to these shorter ultraviolet rays.

In part III, entitled *The Flavone Content of Tropical Plants*, a large body of studies carried out with very diverse plants in various parts of the world is said to confirm the conclusions above stated as regards the relation between flavone and protection from ultraviolet waves of solar origin. Flavone bodies and anthocyanin are said to pass reversibly the one into the other, the former being regarded as an important physiological factor in plant life. Some of the data are reported in tabular form.

**Relation of oxidases and catalase to respiration in plants**, C. O. APPLEMAN (*Amer. Jour. Bot.*, 3 (1916), No. 5, pp. 223-233).—This information has already been noted from another source (*E. S. R.*, 34, p. 523).

**On the relation between transpiration and stomatal aperture**, F. DARWIN (*Phil. Trans. Roy. Soc. London, Ser. B*, 207 (1916), No. 343, pp. 413-437, figs. 23).—The problem which furnishes the subject matter for the present paper, the relation between stomata and transpiration, has already been dealt with to

some extent (E. S. R., 27, p. 222; 31, p. 222). The results, as tabulated and plotted for the ivy, rubber tree, and laurel, are considered to afford convincing evidence that transpiration is regulated by stomatal aperture.

The perception of heliotropic stimulus in plants, GIULIA CAMPANILE (*Ann. Bot. [Rome]*, 13 (1915), No. 2, pp. 139-148).—The author states that in studies with such plants as *Vicia sativa*, *Cicer arietinum*, and *Diploxys*, no constant relation was found to exist corresponding to that suggested in the work of Haberlandt (E. S. R., 31, p. 728) between the presence of certain lenticular cells and the perception of luminous stimuli. In *Colocasia esculenta* and *C. antiquorum* the perception of light stimulus appears to reside in a minute organ of the foliar lamina which is otherwise insensible to light. In case of some fleshy plants where such relation seems to exist, it is said that the reaction still occurs after removal of the epidermis.

The relation between geotropic sensitivity in roots to the presence and orientation of statoliths, VIRGINIA JACOBACCI (*Ann. Bot. [Rome]*, 12 (1914), No. 2, pp. 165-175).—Concluding a study of *Cicer arietinum*, the author states that in case of this plant it appears evident that the presence, in the root tips, of starch grains as statoliths is associated with the reception of gravitational stimulus.

Recent studies on the relation of geotropic sensitivity in roots to the presence and orientation of statoliths, VIRGINIA JACOBACCI (*Ann. Bot. [Rome]*, 13 (1915), No. 2, pp. 149, 150).—Having extended the study above noted to a number of other plants, the author states that the roots which were geotropic generally contained large numbers of statoliths. Results are given of such studies as carried out with *Cucurbita maxima*.

The vitality of seeds buried in the soil, W. J. BEAL (*Proc. Soc. Prom. Agr. Sci.*, 36 (1915), pp. 25-27).—This report has already been noted from another source (E. S. R., 34, p. 732).

Mechanics of dormancy in seeds, W. CROCKER (*Amer. Jour. Bot.*, 3 (1916), No. 3, pp. 99-120).—Discussing theories of longevity, causes of dormancy with methods of securing it, and forcing agents, the author states that dormancy in seeds results generally from the inhibition of one or more of the processes preceding or accompanying germination. Seed coats play an important part in both primary and secondary dormancy. Their colloidal nature permits their easy modification by even low concentrations of a variety of agents, such results having been frequently but wrongly interpreted as stimulus reactions. Regarding germination conditions for both seeds and pollen, it is thought that the recent trend of opinion is toward the need of general physical conditions and away from the need of specific chemical stimuli, or even chemical stimuli at all.

After-ripening of seeds or the changes during dormancy and finally controlling germination may involve growth of the rudimentary embryo, fundamental changes in an otherwise mature embryo, or chemical changes in the coats. In after-ripening, there is often a complex interrelation between coat and embryo changes.

Foliar structure in some oaks having persistent leaves, G. DONATI (*Ann. Bot. [Rome]*, 13 (1915), No. 2, pp. 157-168, figs. 13).—This is mainly a comparative study of leaf structure in *Quercus ilex*, *Q. suber*, *Q. occidentalis*, and *Q. coccifera*.

It is stated that the structure apparent in the study of an individual or of members of a given species varies with the age of the material and with the conditions of the examination. The leaf type in a given species, while varying somewhat as to its minor characters, is still fairly constant. Both internal and external structures of young trees resemble those of older ones of the same species. It is stated that while the foliar structures of *Q. ilex* and those of *Q.*

*coccifera* grown in sun and those grown in shade are much alike, the stem structure shows differentiation as to its characters.

**Mesophyll structure and function in grains,** G. CATALANO (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 25 (1916), 1, No. 2, pp. 112-117*).—Giving a brief account of studies on some typical leaf structures in gramineous plants, more particularly *Chloris gayana*, the author states that a sort of differentiation met with in green parenchyma which forms abundant yellow pigment but no starch indicates a degree of specialization in the foliar tissue corresponding to a division of labor in the general process of nutrition, with resulting economy of total resources.

**The nature of the inflorescence and fruit of *Pyrus malus*,** CAROLINE A. BLACK (*New Hampshire Sta. Tech. Bul. 10 (1916), pp. 519-547, pls. 8; Mem. N. Y. Bot. Gard., 6 (1916), pp. 519-547, pls. 8*).—A morphological study of *P. malus*, including the origin and development of the flower from the incipient shoot and the subsequent formation of the fruit. It deals in considerable detail with the flower bud and its position, the inflorescence, the flower and its essential parts, pollination and fertilization, and the development of the fruit itself.

It is stated that in the Baldwin apple, which was used in the study under discussion, the size of the fruit bud is not a distinguishing character. The fruit bud, rarely axillary, may occur in various positions, being identified with certainty only by dissection. The growth of the fruit bud is characterized by an elongation of the axis, in which wood is formed and upon which flowers, leaves, and buds develop. The bud scales are modified petioles. The inflorescence is a simple cyme. The flower parts develop in succession from the torus, the apex of the axis not being completely used up in the production of the flower parts.

The inferior ovaries are imbedded in the torus, which grows with the carpels. The mesocarp and exocarp of the carpels become fleshy and the endocarp cartilaginous or papery. The torus is the receptacle of the flower and its growth produces the flesh of the fruit, which exhibits a well-defined pith and a cortical layer which are delimited by ten primary vascular bundles, which give rise to the carpellary vascular system.

The fruit of the apple may be regarded as a reenforced or composite fruit consisting of one or more drupe-like fruits embedded in a fleshy torus.

The literature cited is listed.

**Notes on parthenocarpy,** B. LONGO (*Ann. Bot. [Rome], 14 (1916), No. 1, pp. 29-32, fig. 1*).—The author discusses briefly some observations made upon *Monstera deliciosa* and the so-called butter pear, both of which generally produce seedless fruits.

**Department of experimental evolution,** C. B. DAVENPORT (*Carnegie Inst. Washington Year Book, 14 (1915), pp. 127-149*).—Among the principal advances in botany reported during the year are mentioned the discovery that in different strains of *Lychnis* there is a difference in the dominance of one and the same trait, hermaphroditism (including maleness); the proof that inheritance of determiners from both parents by certain plant hybrids leads to more prompt development of characters than in case of inheritance from one side only; the demonstration of a triple factorial basis for the foliage color of *Lychnis*; and the production of a strain of beans with double the number of cotyledons and first leaves of the seedling.

**A new graft hybrid,** A. MANARESÌ (*Staz. Sper. Agr. Ital., 48 (1915), No. 5-7, pp. 513-524, pls. 4*).—An account is given of characters noted in a study of a hawthorn said to be a graft hybrid, the probable origin of which is reserved for later discussion.

Significant accuracy in recording genetic data, E. M. EAST (*Amer. Jour. Bot.*, 3 (1916), No. 5, pp. 211-222).—This is a discussion of supposed disagreements between the statements of findings by the author as previously noted (E. S. R., 29, p. 216), and those made by Goodspeed and Clausen (E. S. R., 34, p. 225).

### FIELD CROPS.

[Work with field crops], L. SMITH (*Rpt. Agr. Expt. Sta. St. Croix, 1914-15*, pp. 1-28, pl. 1).—Experiments with sugar cane, cotton, and a number of minor crops are described.

Work with sugar cane included fertilizer experiments, cultural tests, comparisons of varieties and seedling canes, and bud selection. The fertilizer experiments conducted in several parts of the island showed, in general, that the use of commercial fertilizers can not be relied upon to increase the returns. This is considered as probably due to the small rainfall, which sets a low limit to the growth of the cane. In a series of cultural tests cane was grown in rows 4.5 ft. apart, at intervals of 2, 3, and 4 ft. in the row. The closest planting gave an increase in yield of cane of 20.7 per cent and the medium distance 15.5 per cent over the widest spacing. Three of five bud selections gave a higher yield than ordinary cane, both as plants and ratoons. The results of trials of imported and other varieties of cane are given in tables. Canes B. 4596, B. 6204, B. 7169, and Sealy Seedling are mentioned as giving particularly good results.

Tests of 21 Sea Island cotton selections showed a range in yield of from 208 to 690 lbs. of seed cotton per acre. A 3-acre plat of the first generation hybrid, Sea Island × Sakellarides, planted the middle of August, yielded 3,139 lbs. of seed cotton with the quality equal to that of good Sea Island. The first generation hybrid, Sea Island × St. Croix Native, which was promising a year ago, turned out a complete failure on account of boll dropping.

Cultural tests of maize, imphee, alfalfa, velvet beans, Sudan grass, sorghum varieties, and spineless cactus are briefly noted.

[Fertilizer experiments], A. W. K. DE JONG (*Dept. Landb., Nijr. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab., No. 13 (1915), pp. 27*).—The results of fertilizer experiments with cassava, rice, and citronella grass are reported and briefly discussed.

It was found that as compared with sulphate of ammonia nitrate of soda was taken up more readily by cassava plants. Lime nitrogen as a fertilizer for rice was practically as effective as sulphate of ammonia, while molasses produced no advantage. The use of sulphuric acid applied on rice fields did not appear to produce an injurious effect on the yield. A relatively insoluble phosphate and double superphosphate applied in the ratio of 3:1, respectively, as fertilizers for rice were about equally effective. Volcanic rock used as a fertilizer on citronella grass produced no effect, while a complete fertilizer application gave the largest increase of the different fertilizers tested.

Contributions to the principles of breeding certain agricultural plants.—V, Grasses, C. FRUWIRTH (*Naturw. Ztschr. Forst u. Landw., 14 (1916), No. 3-4, pp. 127-149*).—Continuing previous work,<sup>1</sup> this article discusses observations on the conditions of blossoming and experiments in fertilization of the more important agricultural grasses, including species of *Dactylis*, *Poa*, *Festuca*, and *Lolium*, together with *Phleum pratense*, *Alopecurus pratensis*, *Avena flavescens*, and *Arrhenatherum elatius*.

<sup>1</sup> *Naturw. Ztschr. Land u. Forstw.*, 1 (1903), No. 10, pp. 397-404; 2 (1904), Nos. 1, pp. 18-47; 6, pp. 241-253; 4 (1906), No. 1, pp. 50-55, pl. 1.

In summarizing the results the author states that the grasses studied have their main blossoming stage between five and nine o'clock in the morning, with the exception of *Lolium perenne* and *L. italicum* which blossom a little later, or between ten and twelve o'clock. The blossoming of an individual floret generally lasts from one to two hours, seldom less than one hour but often longer than two hours. No marked difference in this respect among the different species was established.

Blossoming was observed to begin in the upper third of an inflorescence, and in the branches of panicles the flower at the point was the first one to open. With the exception of *Poa pratensis*, the blossoming began with the lowest floret and proceeded upward. It was found that on the average the earlier blossoms produced the heavier fruits. Weather conditions prevailing on a certain day, or even the day preceding, were found to exert a marked influence on the beginning of blossoming and the number of blossoms opening. A retarding effect of the weather gave rise to a larger number of opening blossoms on the day following.

Experiments in the artificial control of temperature, light, and moisture showed that temperature was of much greater importance in its effect on blossoming than the other two conditions. With insufficient temperature blossoming did not take place, but with the proper temperature conditions it was only slightly retarded by the absence of light. High atmospheric humidity did not interfere with blossoming, although it held back the opening of the pollen sacks.

Single blossoms of different grasses inclosed in cotton batting did not produce seed-containing fruits. Similarly inclosed single inflorescences, in the case of only a few grasses, yielded negligible quantities of germinable seed, and two inflorescences from an individual plant produced sexually and inclosed together yielded some fruits which did not germinate and others, somewhat greater in number than those secured from the singly inclosed inflorescences, which were capable of growth. Entire sexually-produced plants when inclosed did not, in many instances, yield a single germinable seed, in others only a small number, and in a few cases a larger number. *L. perenne*, *L. italicum*, and *P. elatius* exhibited the greater tendency toward self-fertilization. The great differences in the behavior of plants of the same species under this treatment are ascribed to individual differences.

Divisions of sexually produced plants inclosed together resulted in a number of cases in the development of a satisfactory number of germinable seeds. The progressive results secured in this series of experiments are considered due to the greater chances of pollination in any particular test as compared with the preceding one.

Experiments with divisions of an individual plant of *A. elatius* showed that complete self-sterility occurs in some grasses. For two years in succession 297 such divisions planted 40 cm. apart each way did not produce any germinable seed.

Some common grasses and how to know them, R. S. MACDOUGALL (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 28 (1916), pp. 56-91, figs. 28).—This paper describes the root, stem, leaf, flower, fruit, and seed of a grass plant, defines the terms used for descriptive purposes, gives a detailed description of each of the more important grasses together with keys in tabular form for their identification, and points out how the seeds of different species may be recognized.

Eleven references to literature on grasses are cited.

A trial of grass mixtures, F. W. HILGENDORF (*Jour. Canterbury Agr. and Past. Assoc.*, 3. ser., 4 (1916), pp. 28-34, figs. 5).—A comparison was made on land of medium fertility of grass mixtures consisting principally of Italian

rye grass, perennial rye grass, cocksfoot, timothy, meadow fescue, red clover, and white clover. The third year after seeding, the seasons of the second and third year having been dry, the Italian rye grass had entirely disappeared, the perennial rye grass had greatly decreased in importance, and the cocksfoot had increased. It was shown that in general an increase in cocksfoot resulted in a decrease of bare land. Timothy and meadow fescue, believed to require heavier land and more moisture than was available during this experiment, were not successful.

**Composition of several of the forage grasses of German East Africa, M. REICH, F. HONCAMP, and H. ZIMMERMANN (*Landw. Vers. Stat.*, 87 (1915), No. 4-5, pp. 351-363).**—The samples of grasses analyzed, selected in the region between the Pare Mountains and the Pangani River, included the following species. *Eragrostis superba*, *E. minor* (?) *Pappophorum scabrum*, *Sporobolus spicatus*, *S. robustus*, *S. rehmanii*, *Aristida adscensionis*, *Cynodon plectostachyum*, *Chloris virgata*, *C. myriostachya*, *C. geryana*, *Dactyloctenium aegyptiacum*, *Leptocarydium, alopecuroides*, *Digitaria horizontalis*, and *Pennisetum ciliare*. Each grass is briefly described and the chemical composition, including the organic and inorganic constituents of the sample representing it, is reported.

***Medicago falcata*, a yellow-flowered alfalfa, R. A. OAKLEY and S. GARVER (*U. S. Dept. Agr. Bul.* 428 (1917), pp. 70, pls. 4, figs. 23).**—This bulletin deals with the history, literature, and certain experimental work relating to *M. falcata*, a yellow-flowered alfalfa, and is an effort to correct extreme and erroneous opinions regarding this plant, setting forth reliable data for the aid of plant breeders and others interested in the species.

The first recorded introduction of *M. falcata* into the United States was by this Department in 1897, followed by importations in 1906 for the purpose of utilizing the species as a cultivated forage crop and by many subsequent introductions, mostly from Russia and Siberia. The species is thought to be indigenous over a large portion of Europe and the western two-thirds of Asia. It occurs throughout a wide range of soil and climatic conditions and at depressions and elevations ranging from below sea level to 13,000 feet above, thus possessing a much wider adaptation than *M. sativa*.

The botanical history of the species has been traced back to the early days of modern botany and is dealt with in some detail. Recent workers differ with regard to the taxonomic relationship of *M. falcata* to *M. sativa*, some regarding it as a true species, while others regard it as a variety or subspecies of the latter. That their relationship is quite close, however, is shown by the readiness with which they hybridize and the fertility of the hybrids.

A classification of the species has been attempted, based largely on the habit of growth. Owing to the extreme variability encountered, many forms are difficult to classify, possessing combinations of characters which make it difficult to determine whether they are of pure or hybrid origin. Four groups have been established, ranging in habit from prostrate to almost erect. Two groups are referred to as pasture groups, not being sufficiently erect to be harvested for hay, and the other two as hay groups.

This species has never been extensively cultivated in Europe or Asia, although utilized to some extent as a wild forage plant. It is now being cultivated to some extent in India and possibly to a still more limited degree in southeastern Russia and Chinese Turkestan.

The erect forms of *M. falcata* resemble those of *M. sativa* in their mass effect, but usually produce a heavier yield in comparison with their bulk, due to the large number of stems. The best strains of *M. falcata* frequently outyield the best strains of *M. sativa* for the first cutting of the season, but *M. falcata* is

seriously deficient as a forage crop in its inability to recover quickly after cutting. Further handicaps of this species as a cultivated crop are that in the West and Northwest, where it appears to hold greatest promise, it can be depended upon to make only one crop a season and that it produces seed sparingly and does not retain its seed as does *M. sativa*.

The natural distribution of the species, its adaptations, and its behavior under field conditions indicate that it is hardy and drought-resistant. Chemical analyses reported indicate that it is about as valuable for feeding purposes as the common alfalfa. The cultural requirements are much the same as those of *M. sativa*, although on account of its hard seed and the slow growth of the young plant it is difficult to secure a satisfactory stand. The plants of *M. falcata* bear transplanting better than do those of *M. sativa*. Sowings on unbroken native sod land gave fair stands, but the plants are not aggressive enough to be of any real value in this respect.

The greatest value of the species appears to lie in the field of selection and hybridization with *M. sativa*. It is hoped that superior strains of alfalfa can be developed from such hybrids.

A list of 67 articles is given, which comprises the literature cited.

**Lucerne inoculation experiment**, J. O. HEINRICH (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 5, pp. 305-313, fig. 1).—The results of four years' inoculation experiments with alfalfa indicated that inoculation with soil from a successful alfalfa field and of the same composition as the land being treated is much more efficient than the use of pure cultures, and that lime greatly increases nodule formation. Pure cultures of the vetch organism were ineffective for alfalfa. In these experiments inoculation without manure gave a lower yield than the check tests, while the plot limed but not inoculated gave the highest yield.

**Alfalfa conditions in New England**, H. W. JEFFERS (*Agr. of Mass.*, 63 (1915), pp. 144-160).—A popular article with discussion on the culture of alfalfa in New England.

**Barley improvement**, F. A. SPRAGG (*Michigan Sta. Circ.* 32 (1916), pp. 3-11, figs. 5).—This circular gives the results to date of variety tests of winter barley in Michigan. Two varieties, Michigan Winter and Derr Winter, seem to give promise for the future, with average yields at the station for the seasons of 1913-1915 of 58.9 and 51.7 bu., respectively. The effect of climatic conditions upon winter barley is shown by numerous reports from farmers.

**Fasciation in maize kernels**, T. K. WOLFE (*Amer. Nat.*, 50 (1916), No. 593, pp. 306-309, figs. 3).—This paper from the Virginia Experiment Station describes two corn kernels, each with two embryos, occurring on an ear representing a cross between Improved Leaming as the seed parent and Boone County Special as the pollen parent, together with their progeny in the F<sub>1</sub> generation.

Two stalks were produced from each kernel and the four ears secured showed Mendelian splitting with reference to white and yellow kernels. All the kernels had only one embryo.

**Work of the Pskof experiment station for flax culture**, N. A. D'IAKONOV (*Selsk. Khoz. i Līšov.*, 249 (1915), Sept., pp. 35-60; Oct., pp. 173-186).—Determinations of the moisture content of fiber flax made at this station showed that under otherwise equal conditions the lower quality of flax has the higher moisture content. Fiber from single dry-stemmed plants was found to contain 84.24 per cent of dry cellulose, while green branched stems contained 81.43 per cent. The results further indicated the value of mass selection of long, single-stemmed plants in improving the quality of the crop. The retting of flax under controlled conditions and with the use of pure cultures of *Bacillus*

*granulobacter pectinovorum* is described. A better yield was secured in a test from seeds stored for more than a year than from fresh seed from the last harvest.

**A handbook of industrial plants in common use**, C. G. FARNSWORTH ET AL. ([Philippine] *Bur. Ed. Bul.* 54 (1915), pp. 111, pls. 24, figs. 49).—This handbook briefly describes the industrial fiber plants of the Philippine Islands with reference to their botanical and other characters, distribution, habitat, and utilization.

**Oat breeding experiments**, J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 7, pp. 457-461, pl. 1).—The breeding experiments with oats here reviewed included mainly cross breeding and selection work with the Algerian variety to increase the height of the straw and to improve the grain from a feeding standpoint. The principal high-grade strains secured in this work are briefly noted, and yields obtained in a comparative test of varieties are reported.

A study of a cross between Algerian and Carter Royal Cluster showed that pigment in the straw behaved as a Mendelian character. In a variety test conducted from 1912 to 1915, inclusive, Algerian ranked first among four varieties with an average yield of 35.99 bu. per acre.

**Observations on potato culture**, V. G. KOTELNIKOV (*Selsk. Khoz. i L'ësov.*, 250 (1916), Apr., pp. 593-603).—Seed tubers of medium size were planted in alternate rows, one and two in a place. The varieties grown were Six-weeks Imperial, and Always Good. Planting two tubers per hill gave a yield 15 per cent greater than the yield from planting only one tuber in a place. The use of large tubers for seed gave somewhat larger yields and a larger percentage of large tubers, but these advantages were not sufficient to offset the profits derived from the use of the smaller tubers.

The influence of overabundant soil moisture during the latter part of the growing season on potato tubers and their starch content, M. P. ARKHANGELSKIĪ (*Selsk. Khoz. i L'ësov.*, 250 (1916), Mar., pp. 400-406, figs. 3).—Studies in progress for two years indicated that the capacity of resisting the malformation of tubers in the presence of an abundance of soil moisture is a heritable character, and showed that tubers of regular shape may have a starch content almost 4 per cent higher than tubers with outgrowths induced by too much soil moisture.

**Further experiments in crossing potatoes**, J. H. WILSON (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 28 (1916), pp. 33-55, figs. 12).—This article describes a number of varieties of potatoes derived from varieties described in an earlier report on this work, previously noted (E. S. R., 19, p. 333). The characters and quality of the different varieties of crosses are set forth, and the behavior of seed sent out for trial is briefly reviewed.

**Harvesting and storing potatoes**, L. MALPEAUX (*Vie Agr. et Rurale*, 6 (1916), No. 40, pp. 238-244, figs. 5).—This article discusses the time and methods of harvesting potatoes and storing the crop, describes storage in cellars and pits, points out briefly the utilization of diseased or otherwise injured tubers, and reports the results of studies on the influence of methods of storing potatoes on their composition. It was found that, in general, storing in cellars was preferable to storing in pits, as there was a smaller loss of dry matter and starch, and the tubers were also in other ways of better quality for table use. The composition of lots of tubers stored for two, four, and six months in cellars and in pits is given in tables.

The soy bean, with special reference to its utilization for oil, cake, and other products, C. V. PIPER and W. J. MORSE (*U. S. Dept. Agr. Bul.* 439 (1916), pp. 20, figs. 3).—This bulletin is a general review of soy-bean production, intended to be of special interest to southern farmers and cotton-oil mill men,

as well as to farmers of the Northern and Central States and the manufacturers of soy-bean food products. Soy-bean production in Manchuria, Japan, Europe, and the United States is discussed in turn, and statistics presented relative to the quantity and value of the exports and imports of the soy bean and its products. The methods of oil extraction are described. Of the two methods commonly used in the United States, the hydraulic and the expeller processes, the latter is the more efficient and cheaper. The uses of soy-bean meal as human food and as stock feeds are discussed and comparative analyses given of soy-bean meal and other important oil meals. The uses of soy-bean oil in various commercial processes and for human consumption are also discussed.

Analyses of over 500 varieties of soy beans grown at Arlington, Va., show that considerable variation exists, the oil ranging from 11.8 to 22.5 per cent and the protein from 31 to 46.9 per cent. The yellow-seeded varieties are deemed most suitable for oil and meal production, and the Mammoth Yellow variety is most generally grown in the South for oil production. Environment appears to be a potent factor in the percentage of oil, wide variations being found in the same variety grown in different localities. Analyses of varieties reported from various sections of the United States indicate that a higher percentage of oil is obtained from the same variety produced by southern-grown seed. Similar results are said to have been obtained in Manchuria. Considerable variation in the percentage of oil was also noted in individual plant selections at Arlington, Va., indicating that improvement may possibly be secured by breeding.

The possibilities of developing a manufacturing industry with American-grown soy beans, especially in regions infested with the cotton-boll weevil, or subject to the danger of infestation in the future, are discussed.

**Tobacco growing in the Connecticut River Valley, L. R. SMITH** (*Agr. of Mass.*, 63 (1915), pp. 266-279, pls. 4).—Historical notes on tobacco growing in the Connecticut River Valley and general directions for the culture of the crop in that section are given. The cost of raising one acre of tobacco is estimated at from \$174 to \$204, and it is stated that the cost of shade-grown tobacco is about 45 cts. per pound.

**Improvement of Ghirka Spring wheat in yield and quality, J. A. CLARK** (*U. S. Dept. Agr. Bul.* 450 (1916), pp. 19, figs. 7).—Among the Russian wheats imported for trial in the dry portions of the Great Plains area, Ghirka Spring wheat has proved to be productive and drought-resistant but low in quality when compared with the standard wheats for that region. The object of these experiments, therefore, was to improve the yield and quality of Ghirka Spring wheat.

A brief history and description of the wheat is given. The experiments were conducted with only one of the Department introductions, Ghirka Spring (C. I. No. 1517) from Grodno Province in Russian Poland. The experimental data include tests of yield, quality, and improvement at several points in South Dakota, North Dakota, and Montana, as well as milling and baking tests conducted at the North Dakota Experiment Station. Much of the data is reported in tabular form and discussed.

The general conclusions drawn from the experiments are as follows: Ghirka Spring wheat is a valuable drought-resistant variety, but is susceptible to rust in moist seasons and in humid areas. It yields on an average more than the Rysting Fife and Haynes Bluestem common wheats, but less than the Kubanka durum wheat. The quality of Ghirka, however, is inferior to that of all the three standard wheats named. Pure line selections numbers 4, 5, and 66 have proved superior to the other selections and to the original unselected mass variety, and compare favorably with the standard spring wheats of the Great

Plains area in both yield and quality. The selections may also prove valuable as material for crossing with varieties possessing greater rust resistance and higher quality.

**Red Rock wheat**, F. A. SPRAGG and A. J. CLARK (*Michigan Sta. Circ. 31 (1916)*, pp. 3-7, figs. 3).—This circular is an extension of Bulletin 268 (E. S. R., 28, p. 141), continuing the results given in that publication up to 1916. Red Rock is especially recommended for Michigan for its winter hardiness, high yield, stiff straw, and its high quality for bread.

**Methods of sowing Poltavki spring wheat**, A. L. GOLODETS (*Bezenchuk. Selsk. Khoz. Opytn. Sta., No. 63 (1915)*, pp. 40).—In experiments with Poltavki spring wheat sown broadcast and in drills 10.5 and 14 in. apart, the drilled seed came up better than that sown broadcast. The wheat in drills 14 in. apart made a more vigorous and leafy growth than that in drills 10.5 in. apart, but in quality was not quite so good, as the grains were smaller and not so well filled out. The soil moisture at the time the heads were forming was the higher in the field with the wider spacing in the drills. A test of different rates of sowing gave the best results from the use of 7 pood per dessyatine (about 1.5 bu. per acre).

**Nitrogenous fertilizers in wheat culture**, L. MALPEAUX (*Vie Agr. et Rurale, 4 (1915), No. 46, pp. 416-418*).—The results of experiments are reported on the use of nitrate of soda and sulphate of ammonia, applied singly or in combination and in varying quantities and on different dates as fertilizers for wheat. Applications were made on the fifteenth day of each of the months of November, December, January, February, March, and April. The best results were obtained from the applications made in February and March. The yields of grain and straw obtained on the different plats in the various series are tabulated.

**A seed-testing key**, A. H. COCKAYNE (*Jour. Agr. [New Zeal.], 13 (1916), No. 2, pp. 129-131*).—Tables compiled from analyses and tests of some 10,000 samples of seeds during the past four years, and giving the progressive average germination of the principal kinds of seeds sent in, are presented for the purpose of indicating the final germination and value of a particular lot of seed when the percentage of germination on a given day after the beginning of the test is known.

**Contribution to testing the germination of grass seeds**, F. KLING (*Jour. Landw., 63 (1915), No. 4, pp. 285-343*).—This article discusses the development of seed control work and its present status, the process of germination and the conditions which influence it, and the methods of making purity determinations and germination tests, and reports the results of germination tests with 14 species of grasses.

The tests conducted showed that while most of the seeds of some grasses germinated in about ten days, the seeds of other grasses required from three to four weeks. In summarizing the results, the grouping of the more important meadow grasses according to the yearly periods of principal development after seeding, as given by other investigators (E. S. R., 28, p. 632; 32, p. 330) is briefly outlined.

The results further indicated that the grasses developing early and quickly also germinate in shorter periods than those reaching full development later. The author bases the following grouping on the time required for germination: (1) Short germinative period, *Phleum pratense*, *Avena elatior*, *Bromus mollis*, *Agrostis stolonifera*, *Lolium italicum*, *L. perenne*, *Festuca pratensis*, and *Dactylis glomerata*; (2) medium germinative period, *Holcus lanatus*, *Alopecurus pratensis*, *Anthoxanthum odoratum*, and *F. ovina*; (3) long germinative period, *Cynosurus cristatus* and *Poa pratensis*.

With reference to methods of conducting germination tests it is concluded that germinating between blotting papers is best for most kinds of grass seed and that light is necessary for the germination of the seed of some species. A constant temperature of 20° C. without light was suited to the germination of only a few grasses, but a change of temperature from 20° for 18 hours to 30° for 6 hours gave good results with many different kinds. A constant temperature of 30° proved unsuited for grass seed germination. *A. pratensis* and *F. pratensis* germinated in the light and also under the temperature changes, and it is suggested that in seed control work both these methods be applied in testing the seeds of these species.

[The examination of beet seeds], M. HEINRICH (*Landw. Vcrs. Stat.*, 87 (1915), No. 6, pp. 381-394).—Four methods of beet seed examination for the purpose of securing samples for making germination tests, referred to as the count, weight, count-percentage, and count-weight methods, respectively, are described, and tests of the relative reliability of the methods are reported. The sources of error are discussed and means for the reduction or elimination of inaccuracies are proposed.

The size relation between dry and soaked seed of clover and dodder, M. HEINRICH (*Landw. Vcrs. Stat.*, 87 (1915), No. 6, pp. 395-408).—This article reports the results of measurements of air-dry and soaked seeds of clover and dodder, compares the differences in size, and points out how soaking may be employed in the removal of dodder seeds.

It was observed that air-dry red clover seed from different sources showed differences in the average measurements which disappeared in part when the seed was soaked. Seed of *Cuscuta trifolii*, when air-dry, was clearly distinguishable from red clover, white clover, and alsike clover seed on account of its smaller size, while air-dry seed of *C. suaveolens* was found also perceptibly smaller than seed of red clover but of equal size with seed of white clover and alsike clover. Soaking increased size differences between the seeds of clover and dodder to such an extent that a difference in size between the seeds of *C. suaveolens* and those of white clover and alsike clover was also plainly perceptible. A method for the removal of dodder seeds from lots of clover seed by means of soaking is described.

[Cooperative experiments in weed eradication] (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 41 (1915), pp. 16, 17; *Rpt. Min. Agr. Ontario, 1915*, pp. 18, 19).—The results of four years' cooperative experiments in weed eradication showed that perennial sow thistle and twitch grass may be eradicated by good cultivation followed by rape sown in drills rather than broadcasted. As compared with buckwheat, rape was the more satisfactory for use in destroying twitch grass. It is further stated that deep cultivation in fall and spring followed by a well-cultivated, hoed crop will destroy bladder campion. Mustard may be prevented from seeding in oats, wheat, and barley by spraying with a 20 per cent solution of iron sulphate without any serious injury to the crop or the fresh seedlings of clover.

[*Pteris aquilina*.—Life history and eradication], G. P. GORDON (*Trans. Highland and Agr. Soc. Scot.*, 5, ser., 28 (1916), pp. 92-106, figs. 11).—The distribution, including the extent and method of spreading, the life history, and the nature of the damage due to the growth of this plant is described, and the results of experiments to determine the best methods for its eradication are reported.

It was found that the plants propagated mainly from the rhizomes, and that spraying them with a 5 per cent solution of sulphuric acid as compared with cutting the plants results in their destruction with greater economy and effi-

ciency. It is recommended that in a normal season the spraying be done early in July and again early in August. The cost of cutting was approximately three times the cost of spraying.

## HORTICULTURE.

Report of the horticulturist, C. F. KINMAN (*Porto Rico Sta. Rpt. 1915, pp. 25-29, pl. 1*).—Investigations with fruits, vegetables, and miscellaneous plants were continued along lines previously noted (*E. S. R., 33, p. 535*).

In the cooperative fertilizer experiments with bearing coconut trees marked gains in yields were recorded for the complete fertilizer plats. Where 10 lbs. per tree of a mixture containing 6 per cent nitrogen, 8 per cent phosphoric acid, and 12 per cent potash was applied a gain of over 30 per cent in yield of nuts per tree over the check plat was obtained. Where 20 lbs. of the mixture was applied per tree the gain in yield of nuts per tree was 60 per cent. Where nitrogen or potash was omitted, no increase in yield was recorded. With the omission of phosphoric acid, there was only a slight increase. The average diameter of the nuts from the different plats has varied but little since 1912, when the experiments were started. Cooperative fertilizer experiments with young coconut palms were commenced during the year.

Thirteen varieties of the imported mangoes in the station orchard fruited during the year and are here listed. Of these, Cambodiana has for several seasons given the most promise for home planting, both from the standpoint of yield and quality. The variety Alphonse, or Bennet, was promising for commercial use during the past year, whereas the formerly promising variety Amini gave poor results, both as to yield and size of fruit. Sandersha continued to be the most prolific variety for use in making preserves or chutney. Observations on the quality of fruit and seedling growth of different wild types found in abundance have shown them to be inferior to the East Indian varieties, both as to the edible and the keeping qualities of the fruits. The slower growth of the wild seedlings makes them less satisfactory than seedlings of the introduced types for use in grafting and inarching. Germination tests of common Porto Rican mangoes show that the best results are secured when the husk is removed entirely from the seed before planting.

The tests to determine the influence of the Porto Rican conditions on northern varieties of vegetables, here summarized, are noted below.

The Smooth Cayenne pineapple, the commercial variety of Hawaii, has not proved satisfactory for general culture in Porto Rico. The algaroba tree (*Prosopis juliflora*) introduced from Hawaii has succeeded well in the southern part of Porto Rico, where the rainfall is light and the soil is sandy.

The bean *Canavalia incurva*, cultivated as a vegetable in a number of Asiatic countries, made poor growth and yield as compared with the jack bean (*C. ensiformis*), and the brown and purple seeded types of *C. gladiata* commonly grown in Porto Rico. The bean *Borot tetragonoloba* from the Philippine Islands has been very thrifty and prolific, although not so rich in quality as many common garden varieties of beans. The vines have large leaves and showy blossoms and are adapted for protecting verandas. A cowpea introduced from India appears to be well suited to conditions in Porto Rico and more valuable as a soiling or cover crop than the types commonly grown.

Experiments on the supposed deterioration of varieties of vegetables in Porto Rico, with suggestions for seed preservation, C. F. KINMAN and T. B. McCLELLAND (*Porto Rico Sta. Bul. 20 (1916), pp. 5-30, figs. 11*).—This paper gives the results in detail of several years' study on the question of the supposed deterioration of varieties of vegetables when grown through several generations in the Tropics.

In conducting the experiment seed of a number of common garden vegetables which had been grown in the North was imported. A portion of the imported seed was kept in viable condition until the experiment was concluded or until the seed was used up by placing it in closed jars which were kept dry by placing in the bottom a few ounces of calcium chlorid. The imported seed and home-grown seed from succeeding generations were planted in beds which were side by side. In order to eliminate as far as possible the factor of varying weather conditions simultaneous plantings were made of as many different generations as possible.

Plantings made of peppers, such as are commonly grown in Porto Rico, side by side with varieties imported from the North showed that the Porto Rican types are much more productive and therefore more desirable than imported varieties. In forty plantings of beans, including nine generations, no indications that advanced generations were inferior to earlier ones were observed. As a rule plantings made in March gave large crops, while those made in other months, including June, September, November, December, and January, gave small crops. During a period of five years thirty-two plantings of okra were made, including eight generations, without any deterioration in the growth and production of the advanced generations. Similar results were secured with tomatoes. In the work with lettuce no degeneration was noted for successive generations, but owing to the difficulty of producing seed during seasons of heavy rain and because of the rapid loss of viability in the seed, it is believed that it will be necessary to import the seed of this crop. In all vegetable plantings the season at which the planting was made had a very pronounced effect on the yield, it being the predominant factor influencing production.

The results are given of germination tests of seed exposed to the air and of seed kept in containers with calcium chlorid. The method of preserving the seed by using calcium chlorid as a drier was so satisfactory that it is recommended for general use.

**Managing the orchard**, J. G. MOORE (*Wisconsin Sta. Bul.* 269 (1916), pp. 47, figs. 26).—A treatise on orchard management with special reference to Wisconsin conditions. Information is given relative to selection of soils and sites, planning the orchard, varieties, planting operations, pruning the young trees, soil management, cover crops and fertilization, pruning the bearing orchard, and spraying practices for different fruits.

**Winterkilling of peach buds**, P. THAYER (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 10, pp. 311, 312).—Tabular data are given showing the records of observations made in the spring of 1914 and that of 1916 with respect to the amount of winterkilling found in the variety orchard at the station.

The observations, as a whole, indicate that the buds on young trees are more apt to be injured than those on mature trees. Winter hardiness does not mean so much resistance to low temperatures as it does resistance to the effects of the January thaw, which starts the buds into life, thus leaving them susceptible to the next moderately cold snap. Varieties appear to behave differently under various conditions. The relative hardiness of varieties for a winter continuously cold may be extremely different from that for a favorable winter.

**Practical fig culture in Arizona**, W. H. LAWRENCE (*Arizona Sta. Bul.* 77 (1916), pp. 43, pl. 1, figs. 15).—This bulletin includes the results of a general field survey of fig culture in Arizona, together with the results of cultural investigations conducted by the station. With the results of the survey and investigations as a basis, directions are given for growing figs, including information relative to the various classes of figs, method of fruiting, climatic requirements, soil, selecting varieties, propagation, arrangement of varieties in the

orchard, planting and care of the young orchard, pruning the bearing trees, cultivation and irrigation, winter protection, caprification, splitting and souring of the fruit, and pests.

Tabular data are given showing the altitude, temperature, and rainfall conditions in sections of Arizona where the fig is grown. Observations and data are also given on the present status of fig culture in different parts of the State and on the growth and condition of 60 trees, representing 43 horticultural forms, that have been under observation for three consecutive seasons, together with yield records of some varieties growing at the station.

During the process of harvesting the 1915 crop the specimens of many varieties were observed to gradually decrease in size with each subsequent picking. In some varieties the size of the fruit decreased during midseason, again increasing in size with subsequent picking. In others, there was an increase in the size of the fruit during the season. There was also a variation in the number of crops produced for the year. One, two, and three crops were produced by different varieties, the number being determined very largely by low temperatures occurring during the winter.

The fruit of the crop of figs, commonly known as Brebas, which is developed in the autumn on the tips of young wood, passes the winter on the naked branches of the trees, and matures the following spring, is usually of good size and can be distinguished from the second and third crops by its position on the wood of the previous season. A study of the varieties of figs grown in the Salt River Valley shows the most hardy and prolific varieties to be Lob Injir, Bulletin Smyrna, Black Mission, Black Adriatic, Bardajic, Rose Blanche, Dauphine, and Ronde Violette Hative. Several other varieties are also recommended for culture.

As a result of the study as a whole the author concludes that the proper selection of varieties will make fig culture possible in a wide range of climatic, water, and soil conditions, such as cover a large proportion of the agricultural area of Arizona.

The chemical composition of American grapes grown in the Central and Eastern States, W. B. ALWOOD ET AL. (*U. S. Dept. Agr. Bul. 452 (1916), pp. 20*).—The present report is supplementary to a bulletin giving the results of analyses during the period 1908 to 1910, previously noted (*E. S. R., 26, p. 441*).

The analyses as here presented include the results for 1911 and 1913, a number of additional grape districts and varieties, including the *Rotundifolia* grapes from North Carolina, being covered by the work. In addition to detailed tabular data the results for sugar and acid determinations of practically all of the varieties examined during the five years' work are summarized.

Report of the assistant horticulturist, T. B. McCLELLAND (*Porto Rico Sta. Rpt. 1915, pp. 30-33, pl. 1*).—A progress report on the station's work with coffee, cacao, and vanilla (*E. S. R., 33, p. 536*).

The testing of foreign varieties of coffee was continued on a larger scale. Additions during the year included the Bourbon and Quillou varieties, several new strains of Robusta, and seeds from selected individuals. Seeds of promising varieties have been widely distributed. An extensive planting of nursery trees made in August, 1914, in which part of the trees were set in permanent location with the roots incased in a large ball of earth from the nursery and part of the transplants were set with the earth removed from the roots, has confirmed previous results relative to the value of transplanting trees with a ball of earth attached. In the first six months the trees transplanted with the roots incased in earth showed more than three times as great an increase

in growth and for the whole year more than double the growth than that made by trees with the roots bare of earth. A year from transplanting nearly 34 per cent of the former and less than 2 per cent of the latter were producing coffee.

Fertilizer experiments with coffee were continued. As heretofore, large increases in yield have been obtained as a result of fertilizing. In a pot experiment nitrogen has been clearly shown to be the element which is most needed for the production of a satisfactory new growth. These experiments show that a need for nitrogen may be indicated by a yellowish-green leaf color. In addition to producing a darker green and more vigorous new growth, nitrogen has had the effect of increasing the number of leaves per plant. Some new experiments were started to determine the value of nitrogen from different sources and also the effect of lime on coffee planted in red clay soil. A further planting of seedlings from a coffee tree which bore both variegated foliage and green leaves indicates that the variegation can be transmitted, although the green foliage is dominant in the offspring.

In the work with cacao the individual yields of more than 300 trees are being recorded. Records have now been kept a sufficient time to show the prolific tendencies of certain individuals. The maximum yield recorded from a single tree at a single picking has been 54 pods. Pickings are made every four to six weeks. For the calendar year 1914 about one-fourth of the trees which were set 11 years before produced no crop. The others averaged 17.5 pods, or a gross return of about 22 cts. per tree. One hundred seedlings from one of the most vigorous and prolific trees have been planted in order to study the differences to be found in seedlings derived from the same tree. Studies are also being made to determine whether there is any correlation between light and dark cotyledons and light and dark beans, the color of the bean being commonly supposed to indicate the quality of the bean,

In the work with vanilla attempts to raise hybrid vanillas from seed have been unsuccessful thus far. Experiments with different lengths of vanilla cuttings for propagating have shown unquestionably that with cuttings up to those of 12 internodes every advantage lies with the longest cuttings. In view of a common opinion that vanilla is a lime lover, applications of lime were applied to four vanilla beds at the rate of 1, 2, 4, and 8 tons per acre. The results indicate that whereas a light liming may be somewhat beneficial heavy liming tends to retard growth.

**Freezing-point lowering of the leaf sap of the horticultural types of *Persea americana*, J. A. HARRIS and W. POPENOE (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 6, pp. 261-268*).**—The results are given of a study of the freezing-point lowering in the cell sap of the Mexican, Guatemalan, and West Indian types of avocados, the plant material being secured from trees growing at the Miami Plant Introduction Field Station.

All of the types showed considerable variation in freezing-point lowering. The range in the freezing point of the sap for the whole series was from 29.43 to 30.27° F. Within the type the absolute variation in freezing-point lowering is very slight, amounting to 0.1° C. or less. The average freezing-point lowering in the Guatemalan and Mexican types was practically the same. The West Indian type is characterized by tissue fluids which freeze at a distinctly higher temperature than in the two other groups of varieties, and is the one which has been shown by horticultural experience to be the least capable of enduring cold. The authors conclude, however, that capacity to withstand low temperatures is not solely due to differences in the freezing point of the sap, this being evident from the slightness of the differences in the cryoscopic

contents of the West Indian as compared with the Mexican and Guatemalan types. Furthermore, the plants of the Guatemalan type are generally considered to be intermediate in hardness between those of the Mexican and West Indian types, whereas no discernible difference in the freezing point of the sap of the Mexican and Guatemalan types was observed.

**The two groups of varieties of the Hicora pecan and their relation to self-sterility,** H. P. STUCKEY (*Georgia Sta. Bul. 124 (1916), pp. 127-148, figs. 10*).—Observations made during a number of years relative to the partial or complete self-sterility of various pecan trees led the author to conclude that there are two distinct groups of varieties of the Hicora pecan. The distinguishing characteristics of these groups are described in general, and the differences and some of the characteristics of the two groups as represented by some of the varieties grown on the station grounds in 1915 and 1916 are presented in tabular form. A bibliography of references dealing with sterility in fruits is included.

Varieties of one group of pecans here observed shed their pollen at about the same time the majority of the pistillate flowers become receptive, whereas the varieties of the other group shed their first pollen after most of the pistillate flowers pass through the receptive stage. Varieties of both groups produce viable pollen, but varieties of the first group are apt to be self-fertile while those of the second group are apt to be self-sterile. Self-sterility of a variety may be expected in proportion to the interval between the receptive stage of the pistillate flowers and the shedding of the pollen. Mechanical injury to catkins before the date of normal pollen shedding may partially prevent self-sterility among varieties of the second group. Parthenogenesis in pecans is also indicated. Phenological data from varieties grown in south Georgia agree fairly closely, as regards the two groups, with that from the varieties at the station. Native hickory trees in the vicinity of the station can be divided into early and late staminate flowering groups, and it appears possible that the hickory will serve as a pollenizer for the pecan.

**The effect of cultural and climatic conditions on the yield and quality of peppermint oil,** F. RABAK (*U. S. Dept. Agr. Bul. 454 (1916), pp. 16*).—In order to obtain data bearing on possible variations in the composition of peppermint oil under varying conditions, plants were grown under various conditions of soil and climate and were harvested at various stages of growth. The oil was distilled from certain parts and also from the entire herb in both the fresh and dry condition and was then subjected to thorough examination. The results are here presented in tabular form and discussed.

Conditions of soil and climate proved to be influential factors in the formation of peppermint oil and its constituents in the plant. Light sandy or loamy soils appear to be most favorable for the production of an oil of high quality. The yield of oil distilled from fresh plants apparently decreases as the plant matures. Drying the plant before distillation results in a considerable loss of oil. The largest proportion of oil is found in the leaves and flowering tops. On the other hand, the formation of esters and menthol in the oils increases as the plants approach maturity and with drying the plants. The formation of esters and menthol takes place most readily in the leaves and tops.

The effect of shade upon the peppermint plant is to decrease esterification and the formation of menthol, whereas the action of frost noticeably increases esterification and the formation of menthol. The decrease in the case of shade-grown plants is possibly due to the lessened activity of the elimination of water by the plant.

## FORESTRY.

The economic woods of Hawaii, V. MACCAUGHEY (*Forestry Quart.*, 14 (1916), No. 4, pp. 696-716).—In this paper the author outlines the chief ecologic zones of Hawaii and gives a descriptive account of the more important economic trees with reference to their distribution and character of tree and wood.

The uses of Formosan trees, R. KANEHIRA (*Indian Forester*, 42 (1916), No. 8, pp. 410-420).—The author here presents a classified list of Formosan trees based upon their uses.

Investigations on the assortment ratios of spruce, silver fir, and beech, P. FLURY (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw.*, 11 (1916), No. 2, pp. 153-272, figs. 3).—This comprises a series of timber estimating tables for individual trees and for entire stands of spruce, silver fir, and beech. Tables are also given showing the percentage distribution of wood-volume in pure even-aged and normal-stocked stands at the ages of 20, 40, 60, 80, 100, and 120 years, respectively. Introductory considerations deal with principles and systems for estimating timber and explain the application of the tables.

Influence of the intensity of thinnings on the yield of young regular stands of fir, E. MER (*Rev. Eaux et Forêts*, 54 (1916), Nos. 7, pp. 185-191; 11, pp. 305-309).—The author gives the results of thinning experiments in some selected fir stands, the actual thinning operations having been started in 1899. The results in general confirm those secured in thinning experiments with young spruce stands (E. S. R., 35, p. 241), indicating that both early and relatively heavy thinnings act advantageously on future yield.

Douglas fir fiber, with special reference to length, H. N. LEE and E. M. SMITH (*Forestry Quart.*, 14 (1916), No. 4, pp. 671-695, pl. 1, figs. 11).—This study, which was conducted under the direction of the Forest Products Laboratories of Canada, deals in most part with length values of Douglas fir fibers as observed in different parts of the same tree and also in different trees. A bibliography of cited literature dealing with fiber measurement studies is included.

Some characteristics of slash pine, W. R. MATTOON (*Forestry Quart.*, 14 (1916), No. 4, pp. 578-588, pls. 2, figs. 2).—A brief discussion of some characteristics of slash pine, with special reference to its rapid spread in second-growth forests, silvicultural qualities, wood structure, and commercial value of young stands.

Seeding of Hevea at different altitudes on Gunong Angsi, F. G. SPRING (*Agr. Bul. Fed. Malay States*, 5 (1916), No. 1, p. 3).—In continuation of previous observations showing that the growth of the tree and yield of rubber are poor at a comparatively high altitude (E. S. R., 30, p. 535), the author here presents data showing that seed production is similarly affected. At about 1,000 ft. the yield of seed commenced to fall off, at 1,800 ft. only a few seeds were produced, while at 2,400 ft. there was no evidence of fruiting.

Ecology of sal (*Shorea robusta*).—II, Seedling reproduction in natural forests and its improvement, R. S. HOLE and PURAN SINGH (*Indian Forest Rec.*, 5 (1916), No. 4, pp. II+43-85, pls. 9).—This is the second contribution on the study of the causes of the dying back of sal seedlings (E. S. R., 32, p. 144). The present paper gives the results of experiments conducted during the period 1912 to 1915 in which sal seedlings were grown in different localities in the shady forests and in the open, respectively. The development of the seedlings was watched throughout the year, and as far as possible the chief factors operative at the season when death or bad growth was noticed were determined.

The forests and streams, A. A. DA SILVEIRA (*As Florestas e as Chuvas. Bello Horizonte, Minas Geraes: Govt., 1916, pp. 54, pls. 33*).—In the present paper the author presents considerable data relative to a number of streams in Brazil to show that there has been a decline in stream flow, but that there is no definite evidence to show that forests have any relation to regulation of stream flow. At the same time attention is called to the importance of planting and extending forests for the production of lumber and other forest products.

The effect of forests upon water circulation, H. A. J. M. BEEKMAN (*Invloed van Bosschen op den Waterkringloop. Surabaya, Java: Nederland.-Ind. Landb. Synd., 1916, pp. 13*).—A paper presented at the Dutch India Soil Congress, Djokja, October, 1916. It briefly summarizes the results of investigations relative to the effect of forests on rainfall and water conservation and introduces similar questions for discussion with reference to East Indian conditions.

National Forest organization, S. W. WYNNE (*Forestry Quart., 14 (1916), No. 4, pp. 589-594*).—In this article the author reviews various propositions made by Woolsey with reference to National Forest organization (E. S. R., 35, p. 451), and calls attention to a number of factors that must be taken into consideration in the development of a management system for the National Forests.

Conversion methods.—A visit to the forests of Chaux and Faye de la Montrond, France, H. R. MACMILLAN (*Forestry Quart., 14 (1916), No. 4, pp. 599-604*).—A brief survey of the forest management systems in the forests of Chaux and Faye de la Montrond.

Yearbook of the department of forestry, (*Ezheg. Liēs. Dcpt., 1 (1913), pp. 125+174, pls. 19, figs. 27; 2 (1913), pp. 353*).—Volume 1 comprises a report on the administration of the Russian forests in 1913, including projects for a new forestry law, the organization of new forest districts, an account of the activity of the permanent forest-culture commission, exploitation of forests, sand-binding work, yields in forest products, revenues, expenditures, etc. Volume 2 gives in tabular form the area of government forest circles in the various Provinces of Russia, with revenues and expenditures therein.

Annual progress report on forest administration in the Presidency of Bengal for the year 1914-15, C. E. MURIEL (*Rpt. Forest Admin. Bengal, 1914-15, pp. 11+47+4*).—This is the usual annual report on the constitution, management, and exploitation of the state forests of Bengal, including a financial statement for the year 1914-15. All important data relative to alterations in forest areas, forest surveys, working plans, forest protection, revenues, expenditures, etc., are appended in tabular form.

Forestry in India from a Canadian point of view, H. R. MACMILLAN (*Forestry Quart., 14 (1916), No. 4, pp. 624-649*).—A survey of forestry and forest conditions in India. Consideration is given to forest distribution and ownership, organization, personnel, research, administration, working plans, silvicultural operations, and financial aspects.

Passing views of forestry in British South Africa, H. R. MACMILLAN (*Forestry Quart., 14 (1916), No. 4, pp. 605-623*).—A general account of the progress and present situation of forestry in South Africa. Information is given relative to the physiography and climate of the different regions of South Africa, forest distribution and composition, development of forestry, present organization, working plans and market, and silvicultural management.

Report of the director of forests, N. W. JOLLY (*Ann. Rpt. Dir. Forests [Queensland], 1915, pp. 8, pls. 3*).—A report relative to the administration and management of the state forests of Queensland, including a financial statement for the year. Tabular data on the sawmilling industry, timber reserves, state forests and national parks, and collections under the timber and quarry regulations from 1908 to 1915 are also included.

China's forest laws, W. F. SHERFESEE (*Forestry Quart.*, 14 (1916), No. 4, pp. 650-661).—This comprises a free translation of the forest laws or mandates issued since the inauguration of the Chinese republic, together with the translation of certain documents dealing with the organization of the present Chinese national forest service.

### DISEASES OF PLANTS.

[**Serious plant diseases in 1914**], D. REDDICK (*West. N. Y. Hort. Soc. Proc.*, 60 (1915), pp. 78-81).—The author states that *Venturia inaequalis*, the cause of apple scab, was destructive throughout the State of New York, the damage done being at least as great as in 1910. Fire blight, due to *Bacillus amylovorus*, was preeminently an apple disease during 1914. No suitable method of controlling the fire blight in old trees has been found, but for young trees, careful pruning and use of corrosive sublimate (1:1000) are the remedies recommended.

Peach leaf curl, due to *Exoascus deformans*, was generally prevalent throughout the State. The many cases noted of successful control are thought to indicate that failures are due to bad method or wrong time of spraying. Peach mildew, due to *Podosphera oxycantha*, was not reported in 1914, owing, presumably, to the absence of fruit.

The raspberry bushes did not show injury from cold until relatively late in the season. Anthracnose (*Glæosporium venetum*) was further studied.

Downy mildew (*Plasmopara viticola*) became destructive in the Keuka Lake region. This is easily controlled with Bordeaux mixture. Powdery mildew (*Uncinula necator*) was abundant in the Chautauqua grape belt. The use of Bordeaux mixture about August 1 is recommended. Dead-arm disease has already been reported (E. S. R., 32, p. 52).

**Report of the plant pathologist**, E. W. BRANDES (*Porto Rico Sta. Rpt. 1915*, pp. 34, 35).—A brief account is given of some experiments for the control of the banana disease described on page 352. In addition, the author has investigated the practicability of controlling diseases of coffee, vanilla, and man-gosteen.

[**Report on plant pathology**], C. H. KNOWLES (*Fiji Dept. Agr. Ann. Rpt. 1915*, pp. 26-31).—This is the report for the division of plant pathology on diseases of economic plants, some ornamentals, and several weeds.

Coconut is attacked by a disease very similar to that caused by *Pestalozzia palmarum*, but this fungus has larger spores. The same leaflets (usually old or unhealthy ones) are sometimes attacked by a fungus identified as *Graphiola cocoina*. The remedy, as also in case of *Pestalozzia*, is restoration of vigor in trees. Coffee at the Nasinu station showed a leaf disease due to *Hemileia vastatrix*.

Cacao brown rot, due to *Thyridaria tarda*, was found at Lami. This fungus also causes a dieback of the younger branches. Pink disease (*Corticium lilacofuscum*) was noted in one locality. Its chief objectionable feature is the splitting of the bark, allowing other fungi to enter. Black rot, attacking mostly young pods, may prove to be due to *Phytophthora faberi*. A brown root disease destroying cacao plants may be the same as that (*Hymenochaete noxia*) causing a similar disease in para rubber, which also shows leaf diseases probably due to *Pestalozzia palmarum* and *P. gucchini*.

A spot disease of banana leaves showed spores of *Cercospora musæ* and other fungi. A nematode, probably *Tylenchus similis*, also causes damage to banana by attacking the roots.

Tobacco showing leaf spots proved to be affected by *Cercospora raciborskii*. Yams are attacked by a leaf disease caused by *Glæosporium pestis*. A leaf spot of sisal plants was found to contain *Macrosporium lanceolatum*. Leaves of cloves bearing reddish or purplish marks, at the Nasinu station, showed a *Peronospora*. Jute showing a leaf spot yielded a *Cercospora*. A tomato wilt could not be traced to any definite cause.

*Kentia macarthurii* showing a leaf spot yielded a *Pestalozzia*. A comparison is made of the spores of the forms of this fungus found on Hevea and Kentia leaves and on ripe fruit of Garcinia. A disease of Livistonia was associated with *Craphiola phœnicis*. *Licuala grandis* showed brown intervenous areas associated with a *Colletotrichum*. Rose leaves were attacked by *Actinonema roseæ*. *Cassia fistula* was apparently attacked by a fungus which was not classified.

Several weeds are named as being attacked by fungi.

Report of the imperial mycologist, F. J. F. SHAW (*Ann. Rpts. Expert Offs. Dept. Agr., Bengal, 1915, pp. 144, 145*).—It is said that experiments looking to the control of ufra disease have been only partly successful. A disease of betel vine occurring near Bogra was found to be caused by *Rhizoctonia destrucns*, particulars regarding which are to be given in a memoir now in press. Anthracnose of betel is said to be a different disease, the causation of which is obscure. Potato blight was studied and the results are to appear later. A disease of areca palm may be due to a form of *Fomes lucidus*.

Report on the first two years' working of the plant protection law (Law No. 5 of 1913), G. STOREY (*Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 1 (1916), pp. 37*).—This contains an account of the legislation for plant protection in force prior and subsequent to the formation of the Department of Agriculture of Egypt in 1911, and of the action as taken in cases arising thereunder; also an appendix giving the new law of 1916, which supersedes the law of 1913.

Besides giving an account of insect pests found in or on plants offered for importation, mention is made of infestation by such parasites as *Cladosporium citri* on oranges from Syria, *Venturia pomi* on apples, *Sclerotinia fructigena* causing a brown fruit rot on peaches from Italy, and *Tylenchus tritici*, which, however, is already present in Egypt on wheat.

Studies on a Fusarium disease of corn and sorghum, L. H. PAMMEL, CHARLOTTE M. KING, and J. L. SEAL (*Iowa Sta. Research Bul. 33 (1916), pp. 115-136, figs. 15*).—A preliminary report is given of a study of a Fusarium disease of corn which is said to have made its appearance in Iowa during 1914 and which was again abundant in 1915, causing a large estimated loss. The fungus attacks the roots, stalks, and ears of the corn. The effects on the different parts of the plant are described, and the results of a study of the organism are given.

The fungus causing the disease is definitely referred to a species of Fusarium, and in connection with the trouble the perithecia of Gibberella has been found, but the authors have not been able to show that this fungus has any relation to the Fusarium. The disease is believed to be spread largely through the seed corn, and careful selection of seed is recommended as a preventive measure.

A Fusarium disease of sorghum, which is similar to, if not identical with, that on corn, is also described.

Clover sickness, A. AMOS (*Jour. Farmers' Club [London], 1916, May, pp. 61-76*).—This is an account, with discussions, of observations on clover sickness, which is ascribed to the presence of *Sclerotinia trifoliorum* or of *Tylenchus devastatrix*, or of both. Several remedies are discussed, but it is thought that clover may be protected from both of these enemies by the same general prac-

tice, namely, that of alternating the red clover crop with sainfoin or trefoil, either alone or mixed with Italian rye grass.

[Ufra disease], G. P. HECTOR (*Ann. Rpts. Expert Offs. Dept. Agr., Bengal, 1915, p. 143*).—Experiments at various points on the control of ufra disease of rice are described. In one set of these, burning the stubble and turning the soil several times controlled the disease completely, while in another set one plat was slightly attacked after this treatment. It is considered improbable that any variety of rice is immune, but some varieties seem to escape owing to their ripening so early as to avoid violent attack.

Resistance in tobacco to the root rot disease, J. JOHNSON (*Phytopathology, 6 (1916), No. 2, pp. 167-181, figs. 6*).—The results of two years' experiments on the relative resistance of selected strains of tobacco to the root rot caused by *Thielavia basicola* are given. The experiments were carried on mainly in Ontario and Wisconsin, the work in Canada being largely with the Burley type of tobacco while that in Wisconsin was confined to cigar leaf selection.

The author states that a strain of White Burley has been developed which possesses a high degree of resistance. Strains of cigar leaf tobacco are known to exist that are practically immune to root rot, but the quality of these types is considered unsatisfactory. Selection breeding is thought to offer the most promising field for investigation for control of this root rot disease.

Host plants of *Thielavia basicola*, J. JOHNSON (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 6, pp. 289-300, pls. 2*).—The results are given of an investigation of the host plants of this fungus, carried on at the Wisconsin Experiment Station in cooperation with this Department.

About 200 species of plants were grown on soil known to be infected with *T. basicola*, and under favorable conditions for the development of the fungus the following families of plants were found to be attacked: Araliaceæ, Bignoniaceæ, Compositæ, Convolvulaceæ, Crucifereæ, Cucurbitaceæ, Hydrophyllaceæ, Leguminosæ, Malvaceæ, Orchidaceæ, Oxalidaceæ, Papaveraceæ, Polemoniaceæ, Portulacæ, Primulaceæ, Scrophulariaceæ, Solanaceæ, and Violaceæ. Among the plants studied, the author added 66 species to the list of known hosts of *T. basicola*, 28 of these being legumes, 20 solanaceous plants, 7 cucurbits, and 11 belonging to miscellaneous families.

It is considered that a difference in the susceptibility of the various species exists, and where earlier investigators have been inclined to doubt the parasitism of the organism, it is believed that their infection experiments were carried on with what are known to be immune or very resistant plants. Basing his conclusion on evidence from nearly 100 species of plants infected with *T. basicola* from tobacco, the author considers that there are no specialized races of this fungus.

Diseases of vegetables, I. C. JAGGER (*West. N. Y. Hort. Soc. Proc., 60 (1915), pp. 140-147*).—This is a discussion of experiences, chiefly with bacterial blight, early blight, and late blight of celery; club root of crucifers, due to slime mold; root knot of cucumbers, tomatoes, lettuce, and other greenhouse plants, due to nematodes; and onion smut.

Cucumber mosaic disease, W. W. GILBERT (*Phytopathology, 6 (1916), No. 2, pp. 143, 144, pl. 1*).—A brief outline is given of work in progress in investigating the mosaic disease of cucumbers, which is known to occur both in greenhouses and in fields.

A new infectious mosaic disease of cucumber, S. P. DOOLITTLE (*Phytopathology, 6 (1916), No. 2, pp. 145-147*).—The author gives a description of field observations and laboratory and field experiments on the cucumber mosaic disease.

No constantly associated organism has been found, but the rapid spread of the disease through fields is considered to indicate that it is highly infectious. As a result of field experiments, the disease was successfully produced through inoculation experiments in which the broken ends of diseased petioles were touched to wounds on cucumber vines, the injection of expressed and filtered juice, insertion of fragments of diseased tissue, etc. Experiments carried on in Michigan indicate that insects, particularly the melon aphid (*Aphis gossypii*), play an important part in the transmission of this disease. Successful inoculations have also been made on pumpkins and muskmelons. In laboratory experiments, a type of infection characterized by the entire wilting of the plant appeared, but it has not been observed in the field.

**Experiments with the cucumber mosaic disease, I. C. JAGGER** (*Phytopathology*, 6 (1916), No. 2, pp. 148-151).—The results of experiments carried out in a greenhouse in the vicinity of Rochester, N. Y., are described.

Successful inoculation was secured when the expressed juices of leaves, stems, and fruits, either filtered or not, were injected into sound cucumber plants. Similar results were obtained by crushing diseased leaves in the hand and then rubbing sound ones, or by growing sound and diseased plants so that the foliage intermingled. Cucumber plants in contact only through their roots did not develop the disease.

In addition to the cucumber, the author reports successful inoculations on the summer squash, pumpkin, and two varieties of gourd.

**Rotting of greenhouse lettuce, I. C. JAGGER** (*West. N. Y. Hort. Soc. Proc.*, 60 (1915), pp. 147, 148).—A discussion of the rots of lettuce ascribed respectively to *Botrytis*, *Rhizoctonia*, and *Sclerotinia* concludes with the statement that the first two can be largely prevented by securing a vigorous growth, keeping the plants and soil surface free from superfluous moisture, and maintaining moderate temperature and humidity. *Rhizoctonia* and *Sclerotinia* can be temporarily controlled by sterilization with steam in the autumn.

**Tomato blight, F. D. HEALD** (*Rpt. Wash. Hort. Assoc.*, 12 (1915), pp. 35-42, fig. 1).—Investigation during 1915 is stated to have shown that the tomato blight, ascribed by Humphrey (*E. S. R.*, 32, p. 444) to one or more species of *Fusarium*, is really caused by a *Rhizoctonia*. The name *Rhizoctonia* disease is selected as most appropriate. The fungus is said to be almost omnivorous. Clean soil, abundant moisture, liberal fertilizer, correction of acidity with lime, deep setting of plantlets, and early fall plowing of suspected soils are recommended as protective measures.

**A troublesome disease on winter tomatoes, J. E. HOWITT and R. E. STONE** (*Phytopathology*, 6 (1916), No. 2, pp. 162-166).—It is stated that in the spring of 1914 tomatoes in forcing houses near Hamilton, Ontario, showed a markedly diseased condition of the leaves, stems, and fruit. Later in the year the trouble reappeared, causing almost complete failure of the crop. This disease, the symptoms of which are described, seems to be rather widely distributed. Repeated microscopic examinations, culture tests, and inoculation experiments have failed to disclose a causal organism.

From the position and nature of the lesions and the fact that the disease fails to develop in affected fruits when they are removed from the plant, the authors have been led to conclude that the disease is a physiological trouble. Experiments with sterilized soil are believed to indicate that the disease is in some way connected with soil conditions.

**Powdery mildew demonstrations on the apple, grape, and peach during the season 1915, L. POWELL** (*Rpt. Wash. State Hort. Assoc.*, 12 (1915), pp. 42-46).—It is stated that in tests made in Benton County, Wash., following out the instructions given by Ballard and Volck (*E. S. R.*, 31, p. 748), satisfactory results

were obtained with the three liquid sprays iron sulphid, atomic sulphur, and milled sulphur on grapevines and peach trees. The experiments with apple trees, though apparently beneficial, are considered to require confirmation by further tests.

**Comparative dusting and spraying experiments,** D. REDDICK and C. R. CROSBY (*West. N. Y. Hort. Soc. Proc.*, 60 (1915), pp. 68-77).—These tests related mainly to insect control, the only disease amenable to the treatments given being apple scab. This trouble was pronounced in some localities in 1913 and very general in 1914.

It is said that the time of application is most important. The dust method is deemed applicable in case of large, old trees, where it is most needed, is from three to six times as rapid as that of spraying, and the total cost for dusting per tree is not greater than for spraying. The mixture, of which 2 to 3 lbs. should be applied to each tree at each time, is 90 per cent sulphur and 10 per cent lead arsenate, the latter being intended for insects.

No reports of injury from breathing the dust have been received. The sprayer is recommended in case of apple varieties which are very susceptible to scab.

See also the bulletin already noted (E. S. R., 34, p. 738).

**Note on apple root rot in Virginia,** C. H. CRABILL (*Phytopathology*, 6 (1916), No. 2, pp. 159-161, fig. 1).—The author states that the root rot previously described (E. S. R., 33, p. 544) is quite prevalent in the Shenandoah Valley and Piedmont section of Virginia. It is more prevalent on new ground, especially where the soil contains decaying wood, and is present in a wide variety of soils and in many localities. In many orchards, several adjoining trees appear to have contracted the disease at about the same time. Some varieties of apples are said to be very susceptible, while others are less liable to attack.

The roots of the infected trees were found to be infested with a delicate white mycelium, and the fungus has been identified as *Trichoderma kocningi*. While the organism is generally considered a wound parasite, the author believes that there is some evidence that it occurs on apple roots as a parasite.

**Apple rosette,** O. M. MORRIS (*Rpt. Wash. State Hort. Assoc.*, 12 (1915), pp. 69-72).—Reporting briefly the results of a survey by correspondence extending over several States, the author holds that apple rosette is somehow connected with the nutrition of the plant. While treatment in some sections should look to improving the humus content of the soil, different means must be employed in other sections, such as drainage and improvement of physical condition.

**Sulphur paste as a spray for peaches,** D. REDDICK (*Phytopathology*, 6 (1916), No. 2, pp. 206, 207).—Attention is called to the ease of preparation and excellent suspension of sulphur paste, which is said to be quite efficient for the control of brown rot and scab of peaches. Directions for the preparation of the paste are given.

**Pear blight (*Bacillus amylovorus*),** T. O. MORRISON (*Rpt. Wash. State Hort. Assoc.*, 12 (1915), pp. 131-133).—This is part of a report by the author on horticultural field conditions in 1915, and deals with the progress at various points during the year of *B. amylovorus*, the cause of fire blight. This is thought to have reached its highest mark during 1914 and to be now somewhat on the decline, which may possibly be accelerated by uniform control measures throughout the orchard districts.

**Further studies in the rôle of insects in the dissemination of fire blight bacteria,** V. B. STEWART and M. D. LEONARD (*Phytopathology*, 6 (1916), No. 2, pp. 152-158).—During the summer of 1915 the authors carried on experiments with *Pollenia rudis*, *Empoasca mali*, *Psylla pyricola*, *Plagiognathus politus*, and

*Sapromyza bispina* to determine the possibility of these insects serving as carriers of *Bacillus amylovorus*.

From previous experiments (E. S. R., 33, p. 744), together with the data given in the present paper, the authors conclude that practically all insects which might be important in producing fire blight infections in nurseries have been considered. The various species of flies were not found active agents in increasing the number of fire blight infections, although when blight is very prevalent and flies numerous, a few infections may be produced by these insects. Most of the infection seems to be transmitted through biting or sucking bugs.

Following the observations of Heald (E. S. R., 34, p. 647), the authors investigated the possibility of infection through the water pores of the leaves. From their investigations there is considered to be little, if any, infection through the water pores, injury to the tissue being necessary before the bacteria can produce infection.

**Preliminary studies on the resistance of *Prunus* to artificial inoculation with *Bacterium tumefaciens*,** C. O. SMITH (*Phytopathology*, 6 (1916), No. 2, pp. 186-194, pl. 1).—In order to determine more resistant stock on which to graft almonds, peaches, etc., the author has conducted inoculation experiments with about 30 species and varieties of the genus *Prunus*.

All the hosts developed typical galls from artificial inoculations except *P. pumila*, *P. ilicifolia*, and *P. caroliniana*. No varieties of almonds or peaches have been found to show marked resistance, but among the plums it is thought that *P. americana* and *P. hortulana* would be well adapted to native species of plums which are not much grown in California. The most popular strains used for grafting were all found very susceptible to crown gall. So far as the investigation has progressed, the author states, no definite recommendation can be made as to the use of resistant stock, although the seedlings of certain German and Italian prunes should be well adapted as a stock for members of the *Domestica* group.

**A Porto Rican disease of bananas,** G. L. FAWCETT (*Porto Rico Sta. Rpt. 1915*, pp. 36-41, pl. 1).—A preliminary account is given of a disease of the variety of banana known as Chamaluco. The disease is said to be quite destructive on this variety, and from diseased tissues a species of *Fusarium* has been isolated which corresponds closely with that described by Ashby (E. S. R., 29, p. 350). Other organisms were found in the tissues, and the author, from his preliminary investigation, is led to believe that the *Fusarium* is only in part the cause of the trouble.

For its control, rotation of crops is recommended, and under present conditions, the variety Chamaluco can be considered only a temporary crop.

**Citrus canker investigations,** W. NEWELL (*Quart. Bul. Plant Bd. Fla.*, 1 (1916), No. 1, pp. 1, 2).—A brief outline is given of the work undertaken by the Florida Plant Board for the eradication of citrus canker in that State.

**Means of identifying citrus canker,** R. A. JEHLE (*Quart. Bul. Plant Bd. Fla.*, 1 (1916), No. 1, pp. 2-10, pls. 9).—The author gives a list of citrus plants which are subject to citrus canker attack, enumerating them in the order of susceptibility to the disease, after which the characteristics of the disease on the leaves, stems, and fruits of the different hosts are described.

**Sour scab of citrus in Florida, and its prevention,** J. G. GROSSENBACHER (*Phytopathology*, 6 (1916), No. 2, pp. 127-142, figs. 4).—The author describes under the name of sour scab a disease of leaves, twigs, and fruits of certain varieties of citrus which have a strongly acid sap in their growing portions.

This name is preferred to the name lemon scab, which was originally given the disease when it was considered to attack lemons chiefly. The disease is known to occur on the sour orange, lemon, citron, certain varieties of grapefruit, etc. Sour scab is said to cause considerable financial loss in the growing of grapefruit in Florida, Cuba, and the Isle of Pines.

The disease develops most destructively in seasons and localities which have abundant moisture in the air and soil during the development of the early spring growth. Trees starting later in growth appear less subject to the disease, and it is thought that possibly selection from such individual trees might prove of value in reducing loss from this trouble.

The cause of the disease is claimed not to have been definitely determined, but among the agents frequently considered to produce the trouble is *Cladosporium citri*. The author's investigations, it is claimed, indicate that this fungus is only partially responsible for producing the disease. The long-continued presence of water on rapidly growing leaves and shoots and on young grapefruits, together with excessive hydrostatic pressures during growth, is believed to have a causal relation to sour scab.

From the reports of experiments covering three years, the author believes that spraying with Bordeaux mixture or lime sulphur solution would protect the fruit. Pruning as a method of restricting the spread has proved impracticable and in some cases even injurious.

**Diseases of forest and shade trees**, D. C. BARCOCK (*Mo. Bul. Ohio Sta.*, 1 (1916), Nos. 10, pp. 291-296, fig. 1; 11, pp. 333-339, figs. 4).—Popular descriptions are given of a number of the more common diseases of forest and shade trees in Ohio, and where definite means are known, suggestions are given for their control.

**An outbreak of white pine blister rust in Ontario**, J. E. HOWITT and W. A. McCUBBIN (*Phytopathology*, 6 (1916), No. 2, pp. 182-185).—The Cronartium stage of the white pine blister rust is said to have been found on five cultivated and four wild species of Ribes in nine counties in the Province of Ontario, and the Peridermium stage has been found on both imported and native white pines. Black currant plantations have in many instances been severely injured. An examination of imported white pines has indicated that they are the source of infection in the majority of cases. According to the authors' observations, the rust may be passed from currant to currant over an intervening distance of at least 800 yds. Spraying experiments indicate that the rust on currants may be markedly reduced by the application of Bordeaux mixture or soluble sulphur. There is thought to be some evidence that the rust may possibly winter on the currant.

**Methods of preparation and relative value of Bordeaux mixtures**, O. BUTLER (*New Hampshire Sta. Sci. Contrib.* 9 (1915), pp. 2-12; *Off. Rpt. Sess. Internat. Cong. Vit.*, 1915, pp. 151-160).—The characters that a copper fungicide must possess are noted, and the three types to which, as previously stated (E. S. R., 31, p. 802), Bordeaux mixtures may be reduced are enumerated, and tabular data reported regarding various phases, properties, and effects of this fungicide.

The author states that acid and neutral Bordeaux mixtures are less injurious to the grape than are the alkaline preparations, although the toxic value of the unit copper is the same in each of these phases of the fungicide. When immediate action is required, the unit copper in acid and in neutral Bordeaux mixture is said to be more effective than is that in alkaline preparations, the last named, however, being more adhesive than the other two.

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

The larger North American mammals, E. W. NELSON (*Nat. Geogr. Mag.*, 30 (1916), No. 5, pp. 385-472, pl. 1, figs. 73).—This paper includes accounts of 57 large North American mammals and colored illustrations from paintings by Louis Agassiz Fuertes of each of the animals considered.

Interim report on the feeding habits of the rook (*Corvus frugilegus*), H. S. LEIGH (*London: Econ. Ornithol. Committee, Brit. Assoc. Adv. Sci.*, 1914, pp. 15).—"The results of this investigation, so far as it has progressed from the consideration of 209 stomachs, show that a large proportion of the food of the rook consists of grain, and that it is taken mainly in the autumn, winter, and early spring months. The total amount of animal food is not so large as grain, but reaches a high percentage during May, June, July, August, and September. There is some evidence to show that a grain diet may be preferred, but there is also evidence which shows that a great many insects (about half of which are injurious) are taken by the rook particularly in its nestling stage, and that it is therefore most important to have a good supply of birds during this phase in its life history. It is difficult from the evidence yet obtained by this inquiry to say whether the rook is on the whole a beneficial or an injurious bird, as the material upon which the account is based is not sufficiently representative."

The rat and infantile paralysis: A theory, M. W. RICHARDSON (*Boston Med. and Surg. Jour.*, 175 (1916), No. 12, pp. 397-400; *chs. in Jour. Amer. Med. Assoc.*, 67 (1916), No. 15, p. 1113).—The author presents facts and reports observations which support the theory that poliomyelitis is transferred by rodents or by insects, or by both. In the transfer of the infection from rat to man the agency of the flea is assumed, although possible contamination of food by rodent excretions is suggested.

The animal parasites of man, the diseases which they transmit, and their treatment, M. BRAUN and O. SEIFERT (*Die tierischen Parasiten des Menschen, die von ihnen Hervorgerufenen Erkrankungen und ihre Heilung. Wurzburg: Curt Kabitzsch, 1915, vol. 1, 5. rev. and enl. ed., pp. X+559, figs. 407*).—This first volume deals with the natural history of the animal parasites of man, including classified bibliography (pp. 451-545). See also the work of Fantham et al. (*E. S. R.*, 36, p. 152).

A new and economically important tapeworm, *Multiceps gaigeri*, from the dog, M. C. HALL (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 2, pp. 214-223, figs. 4).—*M. gaigeri*, of which the dog is the primary and *Capra hircus* the secondary host in India, is described as new.

Report of the entomologist, R. H. VAN ZWALUWENBURG (*Porto Rico Sta. Rpt. 1915, pp. 42-45*).—In the search for a shade tree for coffee in which the hormiguilla (*Myrmelachista ambigua ramulorum*) can not colonize with guest scales, 12 common native tree species were experimented with, but no tree suitable for shade was found in which the ants could not be forced to colonize. Colonies of this ant seem to thrive better and cause more damage when the pink scale (*Coccus* sp.) is the guest than when the mealy bug alone is harbored. The coffee leaf weevil (*Lachnopus* sp.), which is very destructive to coffee at the higher altitudes, has not been observed to occur at an elevation lower than 300 meters (984 ft.). In some districts it is the most serious pest of coffee. It feeds on the edges of young leaves, but the greatest loss is caused through feeding on flowers, young buds, and the newly-set berries.

A common weevil, *Baris torquatus*, was found breeding in the branches of eggplant, in some cases killing the plants completely. Since its developmental stages are passed within the stems of the plant it may be easily controlled by removing and destroying them. A lace-wing (*Corythaica monacha*), which is very common on the eggplant, causes the plants to curl and turn brown.

*Eutermes morio*, which causes great damage to furniture and woodwork, can be effectively controlled at a small expense by placing liberal quantities of any powdered arsenical poison in the runways and nest. A second important termite, which injures woodwork and furniture, probably *Leucotermes* sp., can be effectively controlled by fumigation with hydrocyanic acid gas.

A rhinoceros beetle (*Strategus quadrifoveatus*) in the adult stage often kills young coconut trees by entering the nut below the surface of the ground and eating its way upward, attacking the main shoot.

Several miscellaneous pests mentioned are the round-headed borer (*Apate francisca*) which bores in young mahogany trees and also does damage to coffee, citrus, and gandule or pigeon peas; a lepidopterous larva which disfigures ornamental palms; a noctuid larva (probably *Eriopus floridensis*) on the fronds of ornamental ferns; *Aspidiotus destructor* which often seriously injures coconut trees, especially in the dry region in the southwest corner of the island; a weevil found breeding in the flower buds of eggplant; the larva of *Empyrcuma lichas* which attacks oleanders; etc.

[Papers on insects and insect control] (*Ann. Serv. Épiphyties, Mem. et Rap.*, 2 (1913), pp. 109-155, 188-232, 266-272, 285-301, 311-340, figs. 41).—This second volume (E. S. R., 34, p. 850) includes a number of papers relating to economic entomology, namely, Investigations of the Eudemis and Cochyliis Moths in Bordeaux in 1913 (pp. 109-152) and a Note on the Oblong Scale (*Lecanium persicæ*) and Treatment of Vines Infested by It (pp. 153-155), by J. Feytaud; The Microparasites of Insects and Their Utilization, by A. Paillot (pp. 188-232), which includes a classified bibliography; Observations of the Asparagus Fly and Control Measures, by P. Lesne (pp. 266-272); The Action of Hydrocyanic Acid Gas on the West Indian Peach Scale, by A. Vuillet (pp. 285-287); Note on Coccidæ Received at the Paris Entomological Station in 1913, by P. Vayssière (pp. 288-301); *Holcoeneme cæruleocarpa*, a Sawfly Enemy of Cultivated Ranunculaceæ, by J. Chatanay (pp. 311-320); and *Cleonus mendicus* and *Lixus scabricollis*, Curculionids Injurious to the Beet, by F. Picard (pp. 321-340).

[Report on] economic zoology (*Ann. Rpt. Bd. Sci. Advice India, 1914-15*, pp. 148-166).—The first part of this report (pp. 148-162) by T. B. Fletcher relates to agricultural entomology, and the second part (pp. 162-166), by C. F. C. Beeson, to forest entomology.

Report of the tobacco insect investigations, G. B. MERRILL (*Rpt. Bd. Comrs. Agr. P. R.*, 4 (1914-15), pp. 50-52).—A brief statement of the work of the year with tobacco insects.

The fleabeetles *Epitrix fuscata* and *E. parvula* are said to be the most important insect enemies of the tobacco plant in Porto Rico. The changa or mole cricket, which is injurious in the seed beds and to newly-set transplants, comes next in importance.

Insect pests of tea in northeast India during the season 1915, E. A. ANDREWS (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, No. 1 (1916), pp. 1-6).—This extract from the report of the general committee of the Indian Tea Association for the year ended December 31, 1915, reports briefly upon the occurrence of the more important insect enemies of tea.

Preliminary catalogue of the orthopteroid insects of the Philippine Islands, L. BRUNER (*Univ. [Nebr.] Studies*, 15 (1915), No. 2, pp. 195-281).—In this list, which supplements that of 286 species in Elera's catalogue of the Philippine fauna,<sup>1</sup> the author gives 733 names.

<sup>1</sup> Catálogo Sistemático de Toda la Fauna de Filipinas. Manila, 1895, vol. 2, pp. 189-223.

Second campaign against locusts (*Stauronotus maroccanus*) in Algeria by means of *Coccobacillus acridiorum*, M. BÉGUET (*Ann. Inst. Pasteur*, 29 (1915), No. 10, pp. 520-536).—This is a report of work carried on in continuation of that previously noted (E. S. R., 33, p. 653).

Third campaign against locusts (*Schistocerca peregrina*) in Algeria by means of *Coccobacillus acridiorum*, M. BÉGUET, L. MUSSO, and ÉTIENNE SERGENT (*Bul. Soc. Path. Exot.*, 8 (1915), No. 9, pp. 634-637; *abs. in Rev. Appl. Ent.*, Ser. A, 4 (1916), No. 2, p. 45).—A continuation of the work noted above.

The native food plants of the apple red bugs, R. A. CUSHMAN (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, p. 196).—The author reports observations of the apple red bugs (*Heterocordylus malinus* and *Lygidea mendax*) at Geneva and Westfield, N. Y., and Clearfield, Pa.

"It is evident that the natural food plant of *H. malinus* is not *Pyrus* but *Crataegus*, that the reverse is true for *L. mendax*, and that *L. mendax* is more likely to attack apple than is *H. malinus*. It would seem that a reversal of the specific names would have been more indicative of the true conditions, though not entirely appropriate, since the apple is not the natural food plant of either."

Bedbugs and relapsing fever, V. K. STEPHANSKY (*Russ. Vrach*, 14 (1915), No. 10; *abs. in Jour. Amer. Med. Assoc.*, 65 (1915), No. 11, p. 987).—The author reports that spirochetes ingested by old and young generations of bedbugs engorged upon patients with relapsing fever lost their motility within one hour and disappeared altogether after four or five hours. In experiments in which ten adult bedbugs infected with relapsing fever were killed and an emulsion made of them in normal salt solution, negative results were obtained when injected subcutaneously into monkeys. Sixty-five infected bedbugs and their young were fed once a week on the blood of a perfectly healthy man, who during the course of two months was bitten by them at least 500 times and remained unaffected.

From these results the author concludes that this insect plays no part in the spread of relapsing fever.

A contribution to the knowledge of the bloodsucking Hemiptera of Central America, A. NEIVA (*Brazil Med.*, 29 (1915), No. 1, pp. 1-3; *abs. in Jour. Amer. Med. Assoc.*, 64 (1915), No. 10, p. 867).—This is a preliminary note on the hematophagous Hemiptera of Central America.

The temperature necessary for the destruction of lice and their eggs, A. W. BACOT (*Brit. Med. Jour.*, No. 2874 (1916), p. 167; *abs. in Rev. Appl. Ent.*, Ser. B, 4 (1916), No. 4, pp. 57, 58).—The author concludes "that dry heat or submersion in water at 55° C (131° F.) kills both active lice and their eggs. It follows as a consequence that considerably lower temperatures than those usually employed may be used to destroy these vermin. For the thorough sterilization of infested garments the question of penetration is all-important. It is probable that considerable economy in fuel might be effected by allowing a longer exposure at a lower temperature, while it should be practicable to use quite lightly built chambers or temporarily adapted rooms to obtain dry air temperatures of, say, 60° C. (140° F.)."

Rosy apple aphid, A. C. BAKER and W. F. TURNER (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 7, pp. 321-344, pls. 6).—This plant louse is said to be undoubtedly the most injurious leaf-feeding apple aphid, since its attacks not only injure the foliage and deform the growing apple trees but when abundant or unchecked it deforms the fruit, causing the production of "aphis apples" which are unfit for sale. The present paper is based upon studies conducted during the seasons of 1914 and 1915 in the vicinity of Washington, D. C.

After a careful study of European specimens and the literature, the authors have come to the conclusion that *Aphis malifolia* is the only name to apply to the species. The name *A. sorbi* applies to a different form, originally described from specimens on Sorbus. The authors have been unable to rear the rosy apple aphid on the host plant of the European *A. sorbi*.

Life history studies have been summarized by the authors as follows: "The eggs of this species begin hatching early in April (about April 8 in 1915) and hatching ceases in about a week (April 16 in 1915). The first stem mothers begin reproduction about April 25. From five to seven generations of the spring forms occur on apple in Virginia, although Ross reports the species all summer on apple in Ontario. The first generation is wingless. A few winged forms appear in the next generation and their percentage to the wingless insects increases steadily in each generation until finally all the insects produced become winged. Intermediates may also occur, these acquiring the wingless habits and behaving like wingless insects.

"Migration to plantain commences about May 20, and most of the insects have left the apple by about June 20. A few may continue on apple till about July 1. From 4 to 14 generations of the summer form occur at Vienna, Va. These insects are practically all wingless, only a few occasional winged insects appearing.

"The first fall migrants become adult about the second week of September (September 13 in 1915; these insects were born on August 31). They remain on the trees until after November 1. (In the writers' experiments they were produced till a much later period, but in the field they succumb to prevailing low temperatures more quickly than do either oviparous females or males.) Production of oviparous females commences about the middle to the twentieth of September, but very few are produced till early in October and their production is at its height about the middle of that month. Males begin to appear early in October, at the time the oviparous females begin to become adults, and the males also are most numerous about the last of October and early in November. Oviposition commences the middle of October and continues till the oviparous females are all dead. Some oviparous females may oviposit as late as the latter part of December in case excessive low temperatures have not occurred before that time."

A synopsis of the genus *Calaphis*, A. C. BAKER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 184-189).—The author recognizes five species of this genus from the United States, of which two, *Calaphis castaneoides* and *C. alni*, from specimens on Castanea and on alder, respectively, at Washington, D. C., are described as new.

The development of the *Phylloxera vastatrix* leaf gall, H. R. ROSEN (*Amer. Jour. Bot.*, 3 (1916), No. 7, pp. 337-360, pls. 2, figs. 5).—This paper includes a bibliography of 31 titles.

The San José scale (*Aspidiotus perniciosus*), L. M. PEAIRS and J. H. MERRILL (*Kansas Sta. Bul.* 214 (1916), pp. 5-28, figs. 11).—This is a general account of the San José scale and measures for its control, particularly such as apply to Kansas conditions. Serious infestation by this scale was first found in Kansas in 1906, though it is thought to have been present for some years previous to that date.

The control of the gray scale (*Coccus citricola*) in the San Joaquin Valley, R. P. CUNDIFF (*Proc. Fruit Growers' Conv. Cal.*, 47 (1915), pp. 248-257).—It is stated that in addition to a more or less general infestation in most of the citrus fruit-growing sections south of the Tehachapi Mountains, this scale is now very generally distributed throughout the citrus districts of the San Joaquin and Sacramento valleys. Fumigation is the only successful means of control.

Two destructive fall caterpillars, J. S. HOUSER (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 10, pp. 297-303, figs. 9).—Brief popular accounts are given of the walnut datana caterpillar (*Datana integerrima*) and the yellow-necked apple caterpillar (*D. ministra*). These two leaf-eating caterpillars having somewhat similar habits and appearance have for the past few years attacked walnut and apple trees in all parts of Ohio during the late summer and early fall.

*Laspeyresia molesta*, an important new insect enemy of the peach, A. L. QUAINANCE and W. B. WOOD (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 8, pp. 373-378, pls. 6).—In this preliminary paper the authors call attention to the discovery in the District of Columbia and environs of an important insect enemy of the peach believed to be new to this country and apparently new to science.

A technical description of it under the name *Laspeyresia molesta*, prepared by A. Busck, together with comments on its relationship and possible origin, are incorporated. The authors' observations of it during the summer and fall of 1916 indicate that another formidable insect enemy of the peach and other deciduous fruits has become established in America. The belief that it originated in Japan is strengthened by the rearing from pears received in this country from Japan of a single specimen that can not be differentiated from it. It is said to be generally present on peach trees in yards and elsewhere in the city of Washington and adjacent towns in Virginia and Maryland, within a radius of 15 or 18 miles. It is thought to have been present in the District of Columbia for four or five years, specimens of injured twigs, the injury of which was attributed to an unknown lepidopterous larva, having been received by the Bureau of Entomology in the fall of 1913. A few examples of injured twigs were received or collected during 1914 and 1915, but not until the fall of the latter year were the injuries at all common.

The larvæ have been found injuring twigs of the peach (*Amygdalus persica*), plum (*Prunus* spp.), and cherry (*Prunus* spp.), and the fruit of the peach, but the plum and cherry have not shown such general infestation as observed for the peach, which appears to be the insect's preferred food plant. However, flowering cherries in the parks in Washington are very generally infested. In one peach orchard observed by the authors, an examination in mid-September showed from 80 to 90 per cent of the twigs to have been injured. Its injuries to the twigs of bearing orchards, while important as interfering with normal growth, are of less significance than the injuries of the caterpillars to the fruit. Twig injury in nurseries, however, is of much more importance as the destruction of the terminal growing shoots results in the pushing out of shoots from lateral buds, producing a much-branched and bushy plant unsuitable for nursery stock.

Its attack on the twigs begins in the spring when the shoots are from six to eight in. long and continues until active growth of the tree ceases in the fall. As the twig hardens, the larva may leave its burrow and feed more or less on the exterior of the twig, cutting holes and pits into the bark and causing a copious exudation of gum, rendering the injury quite conspicuous. The larvæ prefer tender, actively growing shoots, and their injury to these is scarcely distinguishable from that of the common peach-twig borer or peach moth (*Anarsia lineatella*). The caterpillars pass from one shoot to another in search for appropriate food and several shoots may be injured by a larva in the course of its growth. The fruit may be attacked while quite green, the infestation increasing as it approaches maturity. In attacking the fruit the young caterpillars rather generally eat through the skin at or near the point of attachment of the fruit stem, the place being indicated by more or less frass adhering

to the surface of the fruit. Entrance is also made at other places, especially where the fruit has been punctured by the curculio or abraded by limbs or branches or other causes. Owing to the combined effect of the caterpillar and brown rot fungus, a good deal of fruit may fall to the ground, though the majority of the fruit infested by the caterpillars will remain hanging on the trees, especially if the fruit was invaded when nearly mature. The authors' observations are not conclusive as to whether the fruit is preferred to the twig.

The larvæ in general appear to be rather indiscriminate in their choice of pupation quarters and may be expected to choose any place on the trees where protection is afforded. The insect hibernates in the full-grown larval condition in silken cocoons, pupation occurring in the spring. Oviposition commences in the spring by the time the shoots of the peach are well out. There are two and probably three broods of larvæ each year.

A new mosquito from the eastern United States, F. KNAB (*Proc. Biol. Soc. Wash.*, 29 (1916), pp. 161-163).—A new mosquito from Laurence Harbor, N. J., is here described as *Culex brehmei*, and brief notes on its habits are included.

The fowl midge (*Simulium nigratarsis*), C. W. MALLY (*Reprint from Cape Times Weekly [Cape Town]*, 1915, Oct. 29, folio).—This simuliid is said to cause a considerable loss of poultry in the Western Province. It becomes abundant when favorable weather conditions prevail, swarms on the fowls at night, and sucks their blood.

Egg disposal in *Dermatobia hominis*, F. KNAB (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 179-183).—The author presents further evidence to show that the female *Dermatobia* attaches its eggs to female mosquitoes of species which have a keen appetite for blood, and in such a manner that the larvæ hatch out and gain entrance to the host at the point at which the mosquito draws blood.

The tachinid genus *Argyrophylax*, W. R. WALTON (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 189-192, figs. 4).—Two male specimens reared from *Nacaleia indicata* at Rio Piedras, P. R., have been identified as *Argyrophylax albincisa*. A description given of the male is accompanied by drawings.

Notes on the larvæ of *Euxesta notata*, R. H. HUTCHISON (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 171-177, figs. 5).—The author records the presence of large numbers of larvæ of this ortalid at Bethesda, Md., during May, June, and July, in swine dung, in accumulations made up largely of bran and other wastes from feed troughs, and in moist bran alone.

A monographic study of the parasitic Diptera of Africa, I, J. RODHAIN and J. BEQUAERT (*Bul. Sci. France et Belg.*, 49 (1916), No. 3, pp. 236-289, pl. 1, figs. 14).—The first section of this paper (pp. 238-262) deals with (*Muscina*) *Passeromyia heterochæta* and the larvæ of dipterous parasites of birds; the second section (pp. 262-289) with (*Cordylobia*) *Stasisia rodhaini*, the source of a cutaneous myiasis in man, its distribution, hosts, parasites, etc. A bibliography accompanies both sections.

Researches on the larvæ of cyclorrhaphous Diptera.—The life cycle of *Pollenia rudis*, parasite of *Allolobophora chlorotica*. Comparative biology of the larvæ of Diptera, D. KELIN (*Bul. Sci. France et Belg.*, 49 (1915), No. 1-2, pp. 15-198, pls. 16, figs. 26).—The first part of this work (pp. 25-106) considers the parasitism of earthworms and the life cycle of the cluster fly (*P. rudis*). The second part (pp. 107-184) relates to the comparative biology of larvæ of the Diptera. In two appendixes the parasites of *P. rudis* and of oligochetes are considered. A bibliography of seven pages is included.

A preliminary note on the bionomics of *Pollenia rudis* in America, J. L. WEBB and R. H. HUTCHISON (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 197-199).—The authors here give a brief summary of the main points bearing di-

rectly on the natural history of the cluster fly (*P. rudis*), as reported by Keilin in the paper above noted. The life history of this fly, a species first discovered in America by the senior author at Washington, D. C., in June, 1916, has been found by the authors to be quite different in many ways from that in Paris, as described by Keilin.

The authors found the eggs of summer generations to hatch in about 3 days. The first stage larvæ are very active and appear to be able to penetrate the earthworms at almost any point in the body wall. The larvæ require from 13 to 22 days and the pupæ from 11 to 14 days to develop, and the total developmental period requires from 27 to 39 days. The authors have reached the tentative conclusion that there are four broods or generations per annum in the latitude of Washington, D. C.

**A curious formation of a fungus occurring on a fly,** L. O. HOWARD (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 196, 197).—This note records the occurrence of a Cordyceps, possibly *C. dipterigena*, on a muscoid fly received from Fayetteville, Ark., and on two specimens in the Pergande collection.

**A new parasite on sheep maggot flies,** W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 7, pp. 505, 506, pl. 1).—A new chalcid found to parasitize blowfly maggots (*Calliphora occanæ*) before they pupate is described as *Chalcis calliphoræ*.

**Ambrosia beetles or pin-hole and shot-hole borers,** C. F. C. BEESON (*Indian Forester*, 42 (1916), No. 4, pp. 216-223, pl. 1).—This account includes lists of 11 species of Ipidæ and 9 species of Platypodidæ which have been found to attack the sal.

**Forest longicorn beetles and their parasites,** W. W. FROGGATT (*Agr. Gaz. N. S. Wales*, 27 (1916), No. 8, pp. 561-567, pls. 3).—Several important Australian longicorn beetles, subsisting on gum timber, and their parasites are considered. Among them is *Phoracantha recurva*, parasitized by three species of braconids here described as new.

**A new species of weevil injuring orchids,** H. S. BARBER (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 177-179, pl. 1).—*Cholus cattlearum*, reared from *Cattleya* orchids probably from Colombia, Venezuela, or northern Brazil, which has been the source of injury to orchids in greenhouses at Washington, D. C., and Milwaukee, Wis., is here described as new to science.

**Pristocera armifera parasitic on Limonius agonus,** J. A. HYSLOP (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 169, 170, pl. 1).—The author records the rearing of this bethylid parasite from a wireworm (*L. agonus*) from material collected in July, 1915, during the course of a serious infestation of corn near Brattleboro, Vt.

**Notes on Dianthidium arizonicum,** W. MIDDLETON (*Proc. Ent. Soc. Wash.*, 18 (1916), No. 3, pp. 193-195, pl. 1).

### FOODS—HUMAN NUTRITION.

**Dietary deficiencies of the maize kernel,** E. V. MCCOLLUM, N. SIMMONDS, and W. PRYZ (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 153-165, figs. 10).—A series of experiments with laboratory animals (rats) are reported in which single or multiple additions of purified substances were made to a diet of ground maize. The substances added were protein, inorganic salts, and butter fat, to supply the unidentified dietary factor, "fat-soluble A." It had been found in earlier experiments that the dietary factor "water-soluble B" is furnished in abundance by even 70 per cent of maize in the diet. The following conclusions are drawn in part from the data reported:

"The proteins of the maize kernel contain all the amino acids essential for growth but the proportions of certain of them are such that they are not utilizable to a high degree as the sole source of protein. When other factors affecting nutrition were properly adjusted, . . . growth [took place] at about two-thirds the normal rate, over a period of six or seven months, on a diet in which all the protein was derived from 91 per cent of ground maize in the ration."

The maize kernel contains both "fat-soluble A" and "water-soluble B," but the former is present in too small an amount for the maintenance of growth at the maximum rate in rats. If the maize diet is supplemented with an alcoholic extract of maize containing the "fat-soluble A," growth is induced which more closely approximates the normal than without this addition, and this was followed by reproduction and rearing of the young.

The inorganic content of the corn kernel is not of suitable character for the promotion of growth, and it was necessary to make salt additions to rations deriving their inorganic content from maize before growth could take place. The authors state that it is evident from experiments carried out thus far, that it is not easy, if at all possible, to make up a satisfactory ration wholly derived from the corn kernel and its parts.

The effects of feeding the proteins of the wheat kernel at different planes of intake, E. V. McCOLLUM, N. SIMMONDS, and W. PITZ (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 211-229, figs. 17).—In this paper the authors attempt to throw some light upon the problem of whether an animal is as well off physiologically with a ration otherwise satisfactorily constituted but containing a high content of protein of low value as when given the same food mixture with the low grade protein replaced by its biologically equivalent amount of a much better protein. These experiments, like others in which a diet high in wheat content was fed, emphasized the marked injury to the progeny resulting from such restricted diets. The authors were not able to make up a ration, containing wheat protein only, which was adequate for the rearing of the young.

"The addition of 10 per cent of casein to a ration which contained 36.33 per cent of protein from wheat, and which was satisfactory with respect to all dietary factors other than protein and an inherent toxicity, improved the ration in a marked degree. Growth was not interfered with by the inclusion of as much as 40.45 per cent of wheat proteins in the diet, but on this the young could not be reared.

"Growth was normal and the production of young was good on a diet containing 46.63 per cent of protein, of which 43.0 per cent was casein, and 3.63 per cent of wheat proteins. The cause of the failure to rear the young on this diet has not yet been definitely ascertained, but would appear to be due in great part at least to the shortage of the supply of the dietary factor 'B,' the sole source of which was the 33 per cent of wheat in the food mixture. As small an amount as 15 per cent of whole wheat as the source of the 'water-soluble B,' suffices for the completion of growth in the rat and so promotes well-being as to induce the production of a nearly normal number of young. The amount of this substance is not great enough to enable the young to develop to weaning age without causing pronounced nervous disturbances which end in death."

The drying for milling purposes of damp and garlicky wheat, J. H. Cox (*U. S. Dept. Agr. Bul.* 455 (1916), pp. 11, figs. 3).—This bulletin reports data showing the proper temperature at which wheat should be dried for milling purposes, obtained in connection with investigations to determine the best method of artificially drying, cleaning, and handling garlicky wheat for mill-

ing. Milling and baking tests made upon samples of the garlicky wheat and damp wheat free from garlic dried at different temperatures indicated that 140° F. is probably the most satisfactory temperature for the drying of the wheat, either with or without garlic, for milling purposes.

"More extensive experiments may show that wheat can be dried at a higher temperature than 140° without having a bad effect on the flour. Every test except one where the wheat was dried at 180° and above gave poorer results in the baking test from the standpoint of loaf volume and texture than when dried at 140°.

"If wheat is dried down to 9 per cent of moisture or below for the removal of garlic, great care must be taken in tempering it back to the normal amount of moisture. In order to restore the moisture content of the dried wheat to normal, which is important for good milling, the wheat should be tempered at least twice, and more if necessary. After the wheat is tempered it should be stored several hours before mixing or before another tempering is made, in order to allow the moisture to penetrate into the kernel. Several hours after the last tempering the wheat should be run from the bin and a thorough mixture made. This last process assists in mixing the dry and wet spots and makes a more even mixture at the rolls."

**Skim milk in the nutrition of adults, G. MOUSSU** (*Compt. Rend. Acad. Agr. France*, 2 (1916), No. 35, pp. 1016-1023).—Regulations are prescribed for the sale of skim milk. These forbid the sale of whole and skim milk by the same dealer and require plain labeling and separate transportation of the skim milk. A special warning is given against the use of skim milk in place of whole milk for feeding very young children.

**Chinese preserved eggs—pidan, KATHARINE BLUNT and C. C. WANG** (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 125-134).—This paper reports the results of an analysis of a kind of Chinese preserved eggs, called "pidan." The substance is a factory product from ducks' eggs and is prepared by covering the eggs with a mixture of lime, salt, water, ashes, and a tea infusion, after which they are stored for five months and then given a further coating of rice hulls.

During the formation of pidan from fresh ducks' eggs a transfer of large quantities of water from the white to the yolk and a loss of water from the white to the outside took place. The ash and the alkalinity of the ash increase, as in the case of other eggs preserved in alkali. The ether extract decreased and its acidity was high. A decrease was also noted in the total and lecithin phosphorus. The noncoagulable nitrogen increased as well as the ammoniacal nitrogen and the amino nitrogen was high in the product.

The conclusion is drawn from the chemical changes undergone that decomposition of the egg protein and the phospholipoids has taken place. The production of pidan is said to be probably brought about through the agency of alkali, bacteria, and enzymes.

**Flavoring extracts, C. H. LAWALL and L. FORMAN** (*Penn. Dept. Agr. Bul.* 285 (1916), pp. 35).—Data are reported regarding the examination of over 200 samples of different flavoring extracts.

[Food and drug inspection], **E. F. LADD and ALMA K. JOHNSON** (*North Dakota Sta. Spec. Bul.*, 4 (1916), No. 8, pp. 179-194).—Data are reported regarding a number of samples of miscellaneous foods, drugs, and patent medicines. A few notes on miscellaneous food topics are included, together with a brief paper on The Laboratory Examination of Drinking Waters by R. Hulbert, which discusses its scope, purpose, and the interpretation of results.

Twelfth annual report of the dairy, food, and oil commissioner, M. GROSHON (*Ann. Rpt. Dairy, Food and Oil Comr. Wyo., 12 (1916), pp. 105*).—This contains information regarding a large number of samples of miscellaneous foods analyzed. The report of T. S. Parsons, seed analyst, is also included.

The economical ration for the times, C. BOLDUAN (*Sci. Amer., 115 (1916), No. 24, p. 529*).—This article describes a dietary worked out by the New York City Department of Health for a family of two adults and three minor children for one week, at a cost of \$7.86. Several suggestions are also given as to ways in which cheaper foods may be substituted for more expensive ones.

Schoolhouse meeting discussion of how to feed the family for health and efficiency, JESSIE P. RICH (*Bul. Univ. Tex., No. 68 (1915), pp. 18, figs. 5*).—A popular bulletin in which 11 questions regarding the diet are answered.

The feeding of prisoners and sanitary conditions in German camps, A. C. GUILLAUME (*Rev. Sci. [Paris], 54 (1916), II, No. 20, pp. 619-624*).—The average daily ration at Holzminden is given as protein, about 55 gm.; fat, 15 gm.; and carbohydrate, 272 gm.; with an average energy value of 1,492 calories.

[Food of the natives of Mailu, British New Guinea], B. MALINOWSKI (*Trans. Roy. Soc. So. Aust., 39 (1915), pp. 546-553, figs. 8*).—A part of a report on the natives of Mailu. Information is given regarding the nature of the food and its preparation and cooking. A number of utensils are also described.

The control of hunger in health and disease, A. J. CARLSON (*Chicago: University of Chicago Press, 1916, pp. VII+319, figs. 39*).—This book summarizes the laboratory work during the last four years of the author and others on the stomach, with special reference to hunger and appetite. The subjects discussed are the biological significance of hunger, the stomach in hunger, some accessory phenomena in hunger, the relation of hunger to appetite, the sensibility of the gastric mucosa, hunger and age, hunger in prolonged starvation, the nervous control of the hunger mechanism, the chemical control of the hunger mechanism, secretion of appetite gastric juice in man, the chemistry of human appetite gastric juice, and hunger and appetite in disease. A bibliography is included.

Results of studies on vitamins and deficiency diseases, during the years 1913-1915, C. FUNK (*Biochem. Bul., 4 (1915), No. 14-15, pp. 304-364, fig. 1*).—This article is a summary and digest of experimental data relative to these subjects, which have been published since the appearance of the author's book (*E. S. R., 32, p. 578*). The subjects considered are beri-beri, scurvy, pellagra, sprue, rickets, the chemistry and physiology of growth, etc. An extended bibliography is appended.

The transmissibility of pellagra.—Experimental attempts at transmission to the human subject, J. GOLDBERGER (*Pub. Health Rpts. [U. S.], 31 (1916), No. 46, pp. 3159-3173*).—The investigation here reported is in continuation of earlier work by the author (*E. S. R., 34, p. 258*). Material (blood, nasopharyngeal secretions, epidermal scales from pellagrous skin lesions, urine, and feces) from 17 severe cases of pellagra was administered to the volunteer subjects of the experiments (16 humans), who afterwards continued their customary habits of life and diet. Observations of the subjects during a period of five to seven months showed that none has developed evidence justifying the diagnosis of pellagra. The author states that, in his opinion, "these experiments furnish no support for the view that pellagra is a communicable disease; they materially strengthen the conclusion that it is a disease essentially of dietary origin, brought about by faulty, probably 'deficient,' diet."

Experimental scurvy produced in guinea pigs by milk and milk products, J. J. MOORE and LELLA JACKSON (*Jour. Amer. Med. Assoc., 67 (1916), No. 26, pp. 1931-1935*).—In these experiments one group of the guinea pigs was fed upon

milk which had been pasteurized by heating to 140° F. for from 25 to 30 minutes, another group was fed upon raw certified milk, and a third was given milk which had been boiled for 10 to 15 minutes. Symptoms of scurvy were produced in most of the animals receiving an exclusive diet of raw, pasteurized, boiled, or skim milk. A severe form of the disease was produced in the animals by condensed milk, casein and water, and several proprietary infants' foods.

A large number of the animals were also fed upon carrots, cabbage, lettuce, and other green vegetables, with hay, for long periods. Symptoms of scurvy were not observed when such a mixture of foods was given, but scurvy was produced in nearly all the young animals when milk was added to these diets of green vegetables. This was rarely true in the case of the older animals.

From a comparison of the results of this investigation with those of other workers, it would appear that a ration which may be entirely adequate in nutritive value for one species may be inadequate for another. "While there is a marked individual variation toward diets in each species, the species variation is still greater."

The paper is followed by a discussion.

Changes in the urea content of blood and tissues of guinea pigs maintained on an exclusive oat diet, H. B. LEWIS and W. G. KARR (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 17-25).—Laboratory animals (guinea pigs), which developed the so-called "scorbutus" as a result of an exclusive oat diet, showed a urea content several times greater than the normal amount. When small amounts of cabbage or oranges were added to the diet, no pathological conditions developed for periods of from 28 to 42 days in the case of the cabbage and 24 to 63 days in the case of the oranges. Analyses of blood and tissues showed a normal urea content. The addition of sodium citrate to the oat diet did not influence the changes resulting from the exclusive oat diet. The changes in the urea content of the organism are not attributed to partial starvation or to lack of water alone, although these factors may be involved to some extent.

The mechanism of the sparing action of carbohydrates on protein metabolism, R. A. KOCHER (*Jour. Biol. Chem.*, 25 (1916), No. 3, pp. 571-576).—Experiments with laboratory animals (dogs) were undertaken to determine the sparing effect upon the output of nitrogen and of the ingestion of lactic and pyruvic acids as compared with the sparing action of equivalent amounts of undissociated carbohydrates. The acid or cane sugar was administered by stomach tube to fasting dogs after the elimination of nitrogen had become constant, and following this determinations were made of the nitrogen excreted in the urine.

The sparing action of lactic acid on protein metabolism was practically the same as that of carbohydrates. That of pyruvic acid, however, was distinctly less. The author states that one of the chief intermediate steps in the dissociation of glucose in the body is the formation of lactic acid, which can be oxidized in the body to pyruvic acid. Also, that lactic acid and pyruvic acid can add on ammonia nitrogen to form alanin, and "when this process is operative, nitrogen arising from catabolism of body proteins, instead of being excreted, is utilized to synthesize new protein." Although the above reactions are reversible, the normal catabolism of glucose gives rise to simpler molecules, which may, in part, be combined with nitrogen to synthesize protein.

These experiments tend to support the theory that the fixation of catabolized nitrogen, by the dissociation products of glucose to form new proteins, is the true mechanism of the sparing effect of feeding carbohydrates on the nitrogen output.

The effect on nitrogen partition of substituting alcohol for sucrose in an otherwise fixed diet, F. S. HAMMETT (*Jour. Biol. Chem.*, 25 (1916), No. 3, pp.

601-605).—Experiments with two men accustomed to a moderate use of alcoholic beverages showed that the substitution, in an otherwise fixed diet, of alcohol for isodynamic amounts of sucrose yielding about 370 calories of energy, produced no significant changes in urinary nitrogen partition.

Concerning the utilization of inosit in the animal organism, I, II (*New York State Sta. Tech. Bul. 54 (1916), pp. 3-16; Jour. Biol. Chem., 25 (1916), No. 3, pp. 391-407*).—Two papers are presented.

I. *Concerning the effect of inosit upon the respiratory exchange in the dog*, R. J. Anderson.—The work of other investigators having shown that inosit given per mouth is either largely destroyed by bacteria in the intestine or else oxidized in the body, determinations were made of the respiratory quotient of laboratory animals (dogs) which in a fasting condition were fed inosit just previous to the experiment, in order to throw further light upon the fate of inosit in the animal organism. The experiments showed that inosit was not utilized to any extent by the dog, and that it was not stored or oxidized in the body, the greater part (as much as 77 per cent of the amount given) being excreted unchanged. When given per mouth at the rate of 2 gm. per kilogram of body weight no rise in the respiratory quotient was noted. Only a small portion of the inosit was found to be excreted by the kidneys.

II. *The effect of inosit upon the metabolism of man*, R. J. Anderson and A. W. Bosworth.—Experiments were made with human subjects to determine whether the ingestion of inosit influences the metabolism of man, as shown by the nitrogen and phosphorus excretion, and also to study the fate of inosit in the human body and its channels of elimination. The results of this investigation are summarized by the authors as follows:

"It is shown that when inosit is taken at the rate of about 0.5 gm. per kilogram of body weight per day it produces some diarrhea at first or frequent soft stools. After a few days the stools, although more frequent than usual, are nearly of normal consistency.

"Except for the increased excretion of creatinin in the after period, for which we can now offer no explanation, we find that the ingestion of inosit has no marked or appreciable effect upon the general metabolism of man. About 9 per cent of the inosit taken per os is eliminated unchanged in the urine, but none in the feces. In what manner the balance, or about 91 per cent, of the inosit is utilized we have not been able to determine."

*The distribution of the lipoids ("fat") in human blood*, W. R. BLOOR (*Jour. Biol. Chem., 25 (1916), No. 3, pp. 577-599*).—The data reported in this paper are based upon complete analyses of the lipoids in the blood of 23 normal and 25 abnormal individuals. The author states that the term lipoids "is used as a general term for all those substances connected with the metabolism of the fatty acids, including the fatty acids, their naturally occurring compounds, and such substances as cholesterol which occur naturally in combination with the fatty acids and which are therefore presumably connected with their metabolism."

A bibliography is appended.

*The urinary and fecal output of calcium in normal men together with observations on the hydrogen ion concentration of urine and feces*, C. F. NELSON and J. L. WILLAAMS (*Jour. Biol. Chem., 28 (1916), No. 1, pp. 231-236*).—From observations made during five days upon five normal male individuals, ranging from 13 to 70 years of age, the extreme daily variations in the output of calcium (calculated as oxid) were found to be in the urinary excretion from 0.1754 to 0.6186 gm. and in the fecal excretion from 0.4125 to 0.801. The subjects of the experiments were maintained upon a mixed diet, which was in no way modified or restricted for the purpose of the experiment.

The calcium and magnesium content of normal urine, C. F. NELSON and W. E. BURNS (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 237-240).—Data are reported regarding the calcium and magnesium content of the urine of 25 apparently normal individuals on an ordinary mixed diet. The results are summarized by the authors as follows:

"The average daily output of calcium and magnesium (calculated as oxid) for five-day periods varied in the cases studied from 0.1685 to 0.1468 gm. of calcium, and 0.1912 to 0.313 gm. of magnesium.

"The daily output of calcium and magnesium of 25 apparently healthy individuals showed 17 in which calcium was excreted in larger amounts than magnesium, and 8 in which magnesium predominated over calcium. The largest amount of calcium (calculated as oxid) excreted in 1 day was 0.4875 gm.; magnesium (calculated as oxid), 0.416 gm. The smallest amount of calcium was 0.099 gm.; magnesium, 0.118 gm.

"Either calcium or magnesium may be excreted by way of the urine in the larger amount in the normal individual. Whichever element predominates does so constantly, or very nearly so, and seems to be independent of the character of the food ingested."

Contribution to the knowledge of the enzymes of the large intestine, D. MAESTRINI (*Arch. Farmacol. Sper. e Sci. Aff.*, 22 (1916), Nos. 11, pp. 391-416; 12, pp. 417-428, figs. 2).—The work of other investigators is reviewed and experiments are reported with laboratory animals (dogs, sheep, etc.).

The author concludes that in the proximal colon the processes taking place differ from those in the other portion of the colon. The proximal colon apparently does not contain a proteolytic ferment similar to trypsin or pepsin but does, however, contain a peptolytic ferment. In the colon of the dog there is a lipase which is not present in that of the sheep. In the case of the dog and the sheep there is present in the first portion of the colon a ferment which breaks down starch. Nitrogen is also present in the colon of both these animals.

### ANIMAL PRODUCTION.

International catalogue of scientific literature. L.—General biology (*Internat. Cat. Sci. Lit.*, 9 (1912), pp. VIII+117; 10 (1913), pp. VIII+138; 11 (1913), pp. VIII+130; 12 (1914), pp. VIII+111; 13 (1916), pp. VIII+93).—These numbers continue the catalogue previously noted (*E. S. R.*, 24, p. 670). The primary divisions catalogued are general biology, methods and apparatus, general morphology, general physiology, and general cytology.

Experimental studies on growth.—VIII, The influence of a diet deficient in fats, and of the same diet with cholesterol added, upon the growth of the white mouse, T. B. ROBERTSON (*Jour. Biol. Chem.*, 27 (1916), No. 2, pp. 393-402, figs. 3).—Continuing the studies previously noted (*E. S. R.*, 35, p. 864), the author reports experiments in which a diet composed of boiled and mashed potatoes, defatted bran, and white of egg, with the addition of small amounts of chlorophyll and ferric chlorid, was fed to mice four or five weeks of age.

The feeding of this diet led to an initial loss of weight, followed by a resumption of the retarded growth. A sharp decline in weight, accompanied by a hyperirritability of the skin and terminating in death, was the ultimate result.

"The addition of cholesterol to the above diet prevents the initial loss of weight, but does not otherwise improve the welfare of the animals, the average duration of life of the animals receiving cholesterol being actually less than that of the animals which do not receive cholesterol. It follows that although growth is possible on the diet described, maintenance of the tissue gained is not. Decline of weight therefore occurs at an age when the diminishing velocity of

growth has become insufficient to compensate for the deficient ability of the tissues to replace their current loss. The variability of animals fed upon the diets described, as is probably to be expected under any unfavorable environmental or dietetic conditions, instead of falling with increasing age and slackening of growth, maintains a high level throughout the life of the animals."

Net energy values for ruminants, H. P. ARMSBY and J. A. FRIES (*Pennsylvania Sta. Bul. 142 (1916), pp. 3-14*).—This paper gives in brief form the results of investigations noted from another source (E. S. R., 33, p. 72).

Net energy values of American feeding stuffs, H. P. ARMSBY and F. S. PUTNEY (*Pennsylvania Sta. Bul. 142 (1916), pp. 15-20*).—Basing their calculations on methods described in the above paper, the authors have computed the net energy values of a number of feeding stuffs from the tables of Henry and Morrison (E. S. R., 34, p. 261). The results are here tabulated, together with the digestible protein and the nonprotein of the feeding stuffs.

War feeding stuffs, M. POPP (*Zent. Einkaufsgesell. Beschränkt. Haftung, Flugschr. No. 6 [1915], Orig., pp. 20, figs. 2*).—This pamphlet briefly discusses the use of various green feeds and roughage, the feeding stuffs produced in the forest, fruits and seeds, and various waste products. Several feeds not recommended for use are also briefly discussed.

The industrial manufacture of war feeding stuffs, M. POPP (*Zent. Einkaufsgesell. Beschränkt. Haftung, Flugschr. No. 7 [1915], Orig., pp. 16*).—This pamphlet discusses the preparation and use of straw meal, hay meal, wood meal, a processed straw meal (made by treatment with dilute alkali), lupine flakes (the alkaloids being removed by aqueous extraction), chestnut flakes, potato press cake, air-dried potatoes, kitchen waste, and yeast.

Cotton-seed meal as an incomplete food, C. A. WELLS and P. V. EWING (*Jour. Biol. Chem., 27 (1916), No. 1, pp. 15-25*).—The experiments here reported are supplementary to previous work (E. S. R., 35, p. 353). From the results obtained it is concluded that cotton-seed meal is an incomplete food, even when fed with sugar and starch on a wide nutritive ratio.

"Pigs upon an absolute maintenance diet ate in addition only small quantities of cotton-seed meal and were not greatly injured by it.

"So-called cotton-seed meal injury is due in large part to inadequate diets."

Chemical composition, digestibility, and feeding value of vegetable-ivory meal, C. L. BEALS and J. B. LINDSEY (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 7, pp. 301-320*).—This is a report of investigations at the Massachusetts Experiment Station upon the chemical composition, digestibility, and feeding value of vegetable-ivory meal. This is the waste product in the manufacture of "vegetable ivory," the seed or nut of the palm-like plant *Phytelphas macrocarpa* (E. S. R., 30, p. 46).

The vegetable-ivory meal used in these experiments was medium fine, white in color with occasional flecks of particles of the brown outer coating of the nut, tasteless, odorless, and very hard. Analyses of nine samples of vegetable ivory showed an average of 11.39 per cent moisture, 4.63 per cent protein, 0.92 per cent fat, 75.09 per cent nitrogen-free extract, 6.89 per cent fiber, and 1.08 per cent ash. Considerable variations were found in the composition of the different samples. The protein rarely exceeded 5 per cent, and was found to contain about one-third of its nitrogen in the amido form. Lignin, galactin, starch, and dextrose were not detected in any of the samples. The nitrogen-free extract was composed principally of mannan, with small amounts of pentosans and of a substance insoluble in alcohol but not identical with the pectin substances usually found in plants. The calorific value of the meal was determined as 1,717 large calories per pound, which compares favorably with that of corn meal, sugar, and corn starch.

In digestion experiments sheep readily ate a mixture of English hay, gluten meal, and finely ground vegetable ivory, 10:3:4 by weight. The average percentage digestibility of vegetable-ivory meal in two experiments in which five sheep were involved was dry matter 84, protein 36, fat 51, fiber 72, and nitrogen-free extract 92. As another means of testing the digestibility of vegetable-ivory meal an experiment was conducted with sheep in which a basal ration of hay and gluten feed was compared with a ration of the same feeds in like quantities plus 200 gm. of vegetable-ivory meal. Each ration was fed for 14 consecutive days and the feces were collected for the last seven days in each period. The feces were tested for total sugar after acid hydrolysis, to note whether the percentage of sugar was higher in the ivory-meal period than in the period without the meal. On a dry-matter basis it was found that the average carbohydrate content, estimated as dextrose, for the feces of the hay, gluten, and ivory-meal period was 25.46 per cent and that for the hay and gluten period was 24.68 per cent. From these results it is concluded that very little of the carbohydrate of the vegetable-ivory meal escaped undigested.

In feeding experiments with cows vegetable-ivory meal was compared with corn meal. In one experiment three pairs of cows were fed on the reversal plan for periods of 5 weeks each a basal ration per cow daily of about 2.5 lbs. of wheat bran, 2.5 lbs. of cotton-seed meal, and 20 lbs. of hay. In addition either 3 lbs. of vegetable-ivory meal or 3 lbs. of corn meal were fed. During the 70 days the cows gained in weight an average of 15.6 lbs. each on the corn meal ration and 1 lb. each on the vegetable-ivory meal ration. During the 35 days the 6 cows were fed the corn meal ration they produced 5,243.5 lbs. of milk, containing 701 lbs. of solids and 239.2 lbs. of fat; and during the 35 days on the vegetable-ivory meal ration they produced 5,072.7 lbs. of milk containing 681.3 lbs. of solids and 236.1 lbs. of fat.

In another test with three cows in which a basal ration somewhat below that needed for maintenance and milk production was used the addition of 3 lbs. per cow daily of vegetable-ivory meal for two weeks increased the milk flow 5.7 per cent. When the cows were returned to the basal ration the milk decreased 4.2 per cent. In another test in which a basal ration with and without vegetable-ivory meal was fed for 81 days the addition of the meal was followed by an increase in milk flow and its removal by a decrease in milk flow.

In another experiment six cows were fed for eight weeks, exclusive of a preliminary period of ten days, a low basal ration of hay, wheat bran, cotton-seed meal, and hominy. In addition three of the cows were fed 2.79 lbs. of vegetable-ivory meal each daily during the first four weeks and the other three cows a like amount of vegetable-ivory meal during the second four weeks. On the basal ration plus vegetable-ivory meal, the six cows produced 3,959 lbs. of milk containing 534.61 lbs. of solids and 190.02 lbs. of fat; and on the basal ration alone they produced 3,826.6 lbs. of milk containing 492.49 lbs. of solids and 179.84 lbs. of fat.

In another experiment eight cows were fed by the reversal system, each period continuing five weeks. Hay, bran, and cotton-seed meal composed the basal ration to which were added like amounts of dry matter in the form of corn meal and vegetable-ivory meal, i. e., 4.01 lbs. daily per cow of corn meal and 3.75 lbs. daily of vegetable-ivory meal. During the experiment the cows on the ration containing corn meal lost 38 lbs. in weight as compared with a loss of 95 lbs. on the ration containing ivory meal. On the corn meal ration the cows produced 6,931.3 lbs. of milk containing 935.85 lbs. of solids and 337.72 lbs. of fat, and on the vegetable-ivory meal ration they produced 6,403.3 lbs. of milk containing 862.23 lbs. of solids and 315.83 lbs. of fat.

From these experiments the authors conclude that vegetable-ivory meal does not fully equal corn meal for milk production.

**Composition and food value of blood meal,** N. HANSSON (*Meddel. Centralanst. Försökskv. Jordbruksområdet, No. 128 (1916), pp. 14; K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 3, pp. 218-229*).—The results of a number of feeding experiments with hogs indicate that blood meal containing from 75 to 80 per cent of protein should be fed in small quantities as a supplementary feed. From 0.6 to 0.7 kg. was readily consumed by a hog per day.

When fed to cattle only about 0.1 kg. per animal per day should be fed at the beginning, and the quantity gradually increased to about 0.75 kg. per day.

In feeding hogs 0.65 kg. of blood meal was equivalent in food value to 1 kg. of corn. The meal proved to be more beneficial during the growing period of hogs than during the fattening period. The animals fed on the blood meal were not so fat as those fed on corn.

No difference in the meat of the experimental and control animals was observed.

**Investigations on the growth of reindeer moss,** K. NISSEN (*Tidsskr. Norske Landbr., 23 (1916), No. 2, pp. 49-64, figs. 7*).—Investigations on the growth of reindeer moss have been begun by the author at Langensjöen, Stenfjeldt, and Flensmarken, but on account of the slow growth of the moss no results are expected on the experimental fields before the lapse of from 10 to 15 years.

**Feeding dairy calves in California,** F. W. WOLL and E. C. VOORHIES (*California Sta. Bul. 271 (1916), pp. 17-44, figs. 10*).—This bulletin reports results of feeding experiments with calves conducted at the University Farm during the past two years to supply information on the value of linseed meal in various grain mixtures for skim-milk calves; carob pods *v.* barley, and dried beet pulp *v.* coconut meal as components of grain mixtures for such calves. A progress report of these tests has already been noted (*E. S. R., 34, p. 265*). The bearing of the results of these experiments on calf feeding problems in the State is discussed, and general information is given relating to the subject of raising calves. The results of chemical analyses of the feeds used in the tests and the digestible components of the feeds on the basis of available digestion coefficients are tabulated.

The calves in each of the lots were fed in addition to the grain mixtures from 10 to 25 lbs. daily of separator skim milk and alfalfa hay ad libitum, except that some whole milk was fed in test 4, and some of the calves in test 5 were fed dry feed only during the latter part of that test. The grains were fed ground or rolled in amounts varying from less than 0.5 lb. to more than 2 lbs. per head daily. Some of the results obtained are shown in the following table:

*Results of calf feeding tests.*

Test.	Lot.	Kind of ration.	Number of calves.	Length of test.	Average age at beginning.	Average daily gain per head.	Feed cost per pound of gain.
I	1	Barley, oats, wheat middlings, linseed meal (2:2:2:1).....	8	70	41	1.13	5.0
	2	Barley, oats, wheat middlings(1:1:1)	7	70	36	1.21	5.0
II	1	Barley, milo maize, and linseed meal (3:2:1).....	8	77	101	2.00	4.4
	2	Barley and milo maize (3:1).....	7	77	95	2.03	4.2
	3	do.....	8	77	42	1.45	3.8
III	.....	Barley, shorts, linseed meal (3:2:1).	5	112	69	2.48	4.2
IV	1	Carob pods, milo maize (1:1).....	8	91	28	1.81	8.9
	2	Barley, milo maize (1:1).....	6	91	30	1.70	8.7
V	1	Beet pulp, barley (1:2).....	7	70	122	2.08	5.8
	2	Coconut meal, barley (1:2).....	7	70	123	1.84	6.3

One calf of lot 2 of the first and second tests is not included in the above table on account of unsatisfactory gains due to constitutional weakness.

In order to test the residual effect of feeding linseed meal the calves in lots 1 and 2 of test 2 were put on pasture without extra feed at the close of the experiment. The average daily gains per head for 160 days on pasture were 1.6 lbs. for lot 1 and 1.59 lbs. for lot 2.

The object of test 3 was to ascertain the gains that may be secured by heavy feeding of skim-milk calves. The daily rations per head in this experiment averaged 2 lbs. of grain, 14.3 lbs. of skim milk, and 7.3 lbs. of alfalfa hay.

The pods from the carob tree (*Ceratonia siliqua*) used in test 4 were crushed in the ordinary machinery used in rolling barley or oats. The crushed pods were greatly relished by the calves. The high cost of gains in this test were due to the fact that whole milk was fed during the first part of the experiment, some of the calves being too young for skim milk. The average daily gains during the last half of this experiment, when skim milk was fed, were 1.87 lbs. for lot 1 and 1.79 lbs. for lot 2, the feed cost per pound of gain being 4.5 cts. and 4.4 cts., respectively.

Charts are given showing the weekly gains of the different lots in each experiment.

**Feeding calves with skim milk and partially hydrolyzed starch, H. EDIN** (*Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 124 (1915), pp. 40, fig. 1; K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 1-2, pp. 83-120, fig. 1*).—Experiments are reported in detail in which a ration prepared as follows was fed to calves with excellent results: Ten kg. of oatmeal was mixed with poor wheat, rye flour, or corn meal, moistened with water, and allowed to soak through the night. Next morning 15 liters of skim milk and as much water were added and the mixture heated to 100° C., with constant stirring to avoid the formation of lumps. The mass was cooled to about 60°, and finely ground brewery malt, previously prepared by mixing 1 kg. of malt with 2 liters of skim milk and carefully warming to 60°, added. The entire mixture was kept at a temperature of from 55 to 60° for some little time and stirred occasionally to prevent any formation of lumps. It was then made up to a volume of 50 liters with skim milk and fed to the animals. The material could be safely preserved with formalin in the proportion of 1:10,000 for later feeding.

Another feed which yielded excellent results was prepared by mixing 1 kg. of skim milk, 50 gm. of starch, 10 gm. of 1 per cent formalin, 2 gm. of chalk, and 1 gm. of salt. The milk was sterilized for 15 minutes by heating to 85°, after which the starch and other materials were added. For partially converting the starch into sugar a suitable quantity of diastase was added.

**Value of alfalfa and other green feed in hog raising, N. HANSSON** (*Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 123 (1915), pp. 29, fig. 1; K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 1-2, pp. 30-56, fig. 1*).—Experiments in hog feeding are reported covering a period of five years with alfalfa combined with skim milk and corn, and with green oats and clover combined with alfalfa.

The results indicate that green feed cut in an advanced stage of development is a good feed for hogs which are being fattened, though its use is not so desirable for young growing pigs. Green fodder should be added to other feed in amounts of from 20 to 22 per cent, and even in greater amounts for suckling mothers. Its food value depends to a large degree on the season in which it is cut, being highest in the summer and autumn. From 7 to 7.5 kg. of alfalfa were equivalent to 1 kg. of corn. Green clover had about the same food value as alfalfa but was not so convenient to use. Green oats, having a lower content of dry matter than alfalfa and clover, has a smaller food value,

from 9 to 10 kg. being equivalent to 1 kg. of corn. The food value of the alfalfa and clover was not increased by cutting or by fermentation and cooking, the only advantage of these procedures being that greater quantities of the fodder are consumed by the hogs. The best results were obtained by gradually increasing the amount of green fodder until the fattening hog had developed a mean weight of from 70 to 80 kg., and then decreasing the amount during the last period of fattening.

The green feed had no influence whatever on the quality of the meat of the animals.

Horse beans were eaten greedily by the hogs and seemed to exert an excellent influence on their growth.

Long-bodied brood sows, E. N. WENTWORTH (*Breeder's Gaz.*, 70 (1916), No. 12, pp. 470, 471).—In experiments at the Kansas Agricultural College 10 large type Poland-China, 2 Berkshire, and 16 Duroc-Jersey sows were divided with reference to body length into the grades very long, long, medium long, medium short, and short. Twenty-one of the sows were in the long grades and seven in the short grades, and all were two-year-olds or over.

The average size of litter for the three grades of long-bodied sows was 9.24 pigs, while the number raised on the average was 5.71 pigs. The average size of litter from the two grades of short-bodied sows was about the same, 9.29 pigs, but the proportion raised was much greater than that of the long-bodied sows, the litters averaging 7.57 pigs at weaning. "One can not say that a medium to short body is desirable as a result of this study, but he can suspect that body length is unrelated to fertility."

Breeding studies of the large white English hog, C. WRIEDT (*Slegtsskapsavlens hos det Store Hvide Engelske Svin. Christiania: Gröndahl & Sons, 1915, pp. 116, pls. 4, figs. 33*).—This manual deals with the wild ancestors of pigs, the original English pig, the Indo-Chinese and Neapolitan pig in England, imported in the sixteenth and seventeenth centuries, and the development and breeding of the leading strains of Large White Yorkshire pigs, including illustrations and pedigrees.

Correlation between the size of cannon bone in the offspring and the age of the parents, C. WRIEDT (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 8, pp. 361-371, figs. 5).—In the investigations here reported, which were conducted at the Illinois Experiment Station, data were collected from measurements of mares recorded in the studbook of the Gudbrandsdal breed of horses of Norway. The measurements were taken of the circumference of the cannon bone near its center at the narrowest point. Causes other than age which have an influence on the size of the cannon bone of the offspring are briefly discussed.

On the basis of measurements of 2,951 mares it was found that the average size of the cannon bone decreases slightly as the age of the sires increases. It was also found that mares whose cannon bones measure more than 19.5 cm. more likely came from sires under 11 years of age than mares whose cannon bones are under 19.5 cm. Investigation was made of the daughters of 10 selected stallions, each of which had more than 25 registered daughters, of which at least 10 were sired before or after the stallion was 10 years old. The average size in centimeters of the cannon bones of 300 mares sired before the stallions were 10 years old was  $19.448 \pm 0.026$  and of 262 mares sired by stallions over 10 years old was  $19.232 \pm 0.027$ .

The correlation between the age of the dams and size of the cannon bone of 1,583 female offspring was studied. The averages show that dams from two to four years old give offspring with the heaviest cannon bone. However, the average cannon bone size of the offspring of dams from 14 to 16 years old was

practically the same as that of the offspring of dams in the classes five to seven and eight to ten years old.

The relation of the age of both parents to the size of the cannon bone of their offspring was studied. The average size of cannon bone was slightly greater in the female offspring of parents both of which were under ten years old than of those from parents either one or both of which were over ten years old. In studying how the measurements of the cannon bones of the female offspring deviate from those of their dams it was found that there was a significant variation only when both parents were ten years old and younger, and in this case the daughters were larger than the dams in cannon bone size.

The author suggests the following conclusions as a result of these studies: "The age of the parent has an influence on the circumference of the cannon bone of the offspring. Immature parents two to four years old give offspring with the same measurement of the cannon bone as parents as old as five to seven years. Parents older than ten years considered as a class give offspring with lighter cannon bones than parents ten years old and younger. In the breed examined there was found a larger percentage of individuals over average size whose parents were ten years old or younger. On the other hand, the average individuals and those smaller have parents which are just as frequently under ten years old as they are over. In other words, the lighter classes of cannon bone come as frequently from young as from old parents, but the heavier classes seem to come more frequently from younger parents. There seems to be some basis for the current opinion among breeders of Gudbrandsdal and other heavy breeds that young parents give better offspring than older parents."

The connection of these data with current genetic hypotheses and conceptions is discussed.

Mules that breed, O. LLOYD-JONES (*Jour. Heredity*, 7 (1916), No. 11, pp. 494-502, figs. 7).—The author comments briefly upon a number of recorded cases of fertility among mules and reviews physiological studies of the germ cells of these animals, which indicate that the chance of mule breeding is very slight.

The effect of the amino-acid content of the diet on the growth of chickens, T. B. OSBORNE, L. B. MENDEL ET AL. (*Jour. Biol. Chem.*, 26 (1916), No. 2, pp. 293-300, pl. 1).—Feeding experiments are reported in which two pairs of chickens (Rhode Island Reds) were fed, the one on a ration consisting of corn gluten, "protein-free" milk, starch, butter fat, and lard, and the other on the same ration plus lactalbumin. The mixed protein of the corn-gluten ration was considered to yield about 1 per cent of lysin, while the ration with the lactalbumin yielded a considerably larger quantity. During the course of the experiment one chick of each pair died from causes not ascertained.

The chick receiving the corn-gluten feed made a total gain in 55 days of 52 gm., while the chick receiving the corn gluten plus lactalbumin ration made a gain of 283 gm. in the same period.

It is indicated that the "observations corroborate, for the chick, the experience which we have previously published regarding the unlike value of different proteins in the nutrition of growth."

Further experiments are reported which demonstrate that cottonseed flour forms a suitable adjuvant for the proteins of corn gluten, as two chicks fed on such a ration made gains of 284 and 322 gm., respectively, in 53 days, as compared to a gain of only 52 gm. in 55 days by the chick fed the corn-gluten ration noted above.

It is indicated that in view of the work recently reported by Drummond (E. S. R., 35, p. 472), in which it was maintained that it is impossible to rear

to a satisfactory degree of development young chicks kept under the artificial conditions prevailing in the laboratory, further experience seems essential before a final conclusion in respect to the problem of the experimental feeding of young chicks can be promulgated. The rapid growth of this species, however, renders chicks especially suitable for experiments on growth.

See also a previous note by Buckner, Nollau, and Kastle (E. S. R., 34, p. 871).

**Cottonseed meal—a good feed for laying hens**, E. P. CLAYTON (*Mississippi Sta. Bul.* 175 (1916), pp. 7, fig. 1).—In continuation of work already noted (E. S. R., 30, p. 175) results are here given of feeding cottonseed meal to laying hens and to broilers.

In one test with old laying hens two lots of 9 hens each were fed a commercial scratch feed and a mash of corn meal, wheat bran, and oats. In addition, one of the lots was fed cottonseed meal to the extent of 11 per cent of the mash and the other lot beef scrap to the extent of 5.5 per cent of the mash. The cottonseed meal fed hens laid 249 eggs during the test, at a feed cost per dozen of 32.4 cts., and the beef scrap fed hens 174 eggs, at a cost of 40.8 cts. per dozen.

In another test with old White Leghorn hens two lots were fed a commercial scratch feed and a mash of corn meal and wheat bran. In addition, the 14 hens in lot 1 were fed cottonseed meal to the extent of 22 per cent of the mash and the 7 hens in lot 2 beef scrap to the extent of 11 per cent of the mash. One hen of lot 1 died at the beginning of the fourth month of the 6-months test. The hens in pen 1 laid 396 eggs, at a feed cost of 18 cts. per dozen, and those in pen 2, 200 eggs, at a cost of 24 cts. per dozen. It is stated that the increased egg production of the cottonseed meal fed hens was especially noticeable during the fall molt.

Results are also given of feeding tests with broilers indicating that cottonseed meal, when it comprises 25 per cent or less of the mash, is a good feed for fattening broilers.

As a result of experience with the general flock the station recommends the feeding of cottonseed meal to poultry in amounts not exceeding 25 per cent of the rations. The author states that pullets at the station grow rapidly and mature and begin to lay early when fed a mash containing at first 15 per cent and later 25 per cent of cottonseed meal. Formulas are given for mashes and grain mixtures for laying hens and young chicks.

**Rations for laying hens in winter**, W. J. BUSS (*Mo. Bul. Ohio Sta.*, 1 (1916), No. 11, pp. 324, 325).—Brief results are given of an experiment to determine the relative efficiency and economy of a ration of corn, wheat, and oats and one believed to be well balanced for egg production. Soy beans and meat scrap were also compared in this test as sources of protein for laying hens.

There were four lots of 21 Barred Plymouth Rock pullets each used in the experiment. Lot 1 was fed corn, wheat, and oats (3:2:1 by weight); lot 2, corn and wheat (3:1) and a mash of ground corn, bran, and meat scrap (2:1:2); lot 3, corn and wheat (3:1) and a mash of ground corn, bran, ground soy beans, and meat scrap (4:4:5:5); and lot 4, corn, wheat, and soy beans (3:1:1) and a mash of ground corn, bran, and ground soy beans (2:1:2). All the lots received grit and all except lot 1 oyster shells. During the test which lasted from October 28, 1915, to March 15, 1916, the pullets in lot 1 produced an average of 3.08 eggs each at a feed cost per dozen of \$1.55; lot 2, 32.21 eggs each at a feed cost of 21 cts. per dozen; lot 3, 22.95 eggs at a feed cost of 28 cts. per dozen; and lot 4, 7.37 eggs each at a feed cost of 76 cts. per dozen.

**The logic of the winter feeding schedule**, MR. and MRS. G. R. SHOUP (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 4 (1916), No. 8, pp. 9-15).—Continuing the experiment previously noted (E. S. R., 34, p. 669) results are reported which

show that from November 9, 1915, to January 3, 1916, the hens of lot 1 produced 1,267 eggs (22.4 per cent production) as compared to 3,017 (53.8 per cent production) produced by the hens of lot 2. Following slight modifications in the feed of lot 1 the egg production was markedly increased (41.9 per cent production), while following the use of artificial light early in the morning and late at night the production was raised to 60 per cent.

It is concluded that the increase in production was due chiefly to the use of the lights, while the protecting of the hens and the feed used are also deemed necessary for the maximum egg production.

The feeds used and the management of the flocks are briefly described.

### DAIRY FARMING—DAIRYING.

Computation of dairy rations, F. S. PUTNEY and H. P. ARMSBY (*Pennsylvania Sta. Bul. 143 (1916), pp. 3-24, fig. 1*).—On the basis of computations and tables outlined previously (*E. S. R., 27, p. 176*) and as noted on page 367, the authors discuss feeding standards, the art of feeding, the selection of feeding stuffs, the compounding of grain mixtures, the cost of rations, rations on pastures, and condimental and proprietary feeding stuffs. Convenience tables for computing grain mixtures, specimen grain mixtures, and tables showing the dry matter and digestible protein contents and net energy values of a large number of feeding stuffs are included.

Osage oranges for dairy cows, J. J. HOOPER (*Breeder's Gaz., 70 (1916), No. 13, p. 537*).—In tests at the Kentucky Station cows were fed from 1 to 10 Osage oranges daily per head for periods of from two weeks to one month, in addition to grain, hay, and silage. The oranges were chopped fine and mixed with the grain. A few of the cows refused to eat the oranges, but others seemed to like them.

It is stated that the oranges can be kept for winter use by burying in a mound of earth.

The effect of feeding on the composition of milk and butter.—Dried yeast and decorticated cotton meal, H. T. CRANFIELD and MARGARET G. D. TAYLOR (*Analyst, 41 (1916), No. 485, pp. 240-245, fig. 1*).—Experiments in which the feeding value of dried yeast and cotton-seed meal was compared with regard to milk production are described.

The results indicate that dried yeast is an excellent feed for dairy cows as regards the quality of milk and butter. The deficiency of fat in the ration does not appear to influence the quality of the milk or milk fat. A higher Polenské value in the fat from the animals that received the dried yeast was the only marked variation observed.

An increased yield of 41.25 lbs. of milk and 3 lbs. of milk fat were obtained in favor of the dried yeast during the four weeks of the experiment.

Variations in the composition of skim milk, A. E. PERKINS (*Mo. Bul. Ohio Sta., 1 (1916), No. 10, pp. 304-306*).—A brief report is given of studies upon the variation in composition of skim milk derived from milk containing different amounts of fat. The variation in the fat content of skim milk is not discussed.

The ash content of skim milk varies with the fat and protein content, usually ranging from 0.65 to 0.85 per cent. It is stated that for practical purposes the protein and sugar content of skim milk may be computed from the analysis of whole milk by multiplying the protein and sugar contents of the whole milk by 1 plus the fat content of the whole milk. By this method and using analyses by other experiment stations of whole milk, the average per-

centage content of protein and sugar in skim milk from different breeds of cows was calculated as follows: Ayrshire, 3.46 and 5.2; Holstein, 3.25 and 4.8; Guernsey, 4.04 and 5.23; Jersey, 3.99 and 5.30; and Shorthorn, 3.44 and 5.07, respectively. On the basis of analyses of whole milk at the Ohio Station, the skim milk from three Holstein cows was calculated to contain 3.12 per cent protein and 5.06 per cent sugar, and from four Jersey cows 4.26 per cent protein and 5.18 per cent sugar.

To further test the relation of the fat content of whole milk and the composition of skim milk obtained therefrom, analyses of 807 samples of 10 groups of milk made at the Ohio and other stations are summarized. These groups ranged in fat content from an average of 2.19 per cent to 7.4 per cent. The percentage of protein in the skim milk was found to undergo a regular and progressive variation, being at its lowest point of 2.67 per cent in the extreme low-testing fat group and increasing regularly as the fat test increased, though not so rapidly. An increase of 5.21 per cent of fat between the average test of the first and last group was accompanied by an increase of only 2.38 per cent in the protein content of the skim milk. The sugar content in general varied with the protein content, but the variations were not so regular or marked. It was found that the fat content of mixed milk from several cows or of a composite sample of several milks from one cow does not often show much change without a corresponding variation in the skim milk solids.

The author concludes that "the fat content of milk as indicated offers a convenient and practical basis for computing with reasonable accuracy the composition of the skim milk derived from it."

**The significance of the act of milking**, C. CROWTHER (*Rpt. Brit. Assoc. Adv. Sci.*, 85 (1915), pp. 779, 780).—Data are offered in support of the hypothesis that in addition to the removing of preformed milk in the udder the operation of milking may impart a stimulus to further vigorous secretion during the period of milking.

Milking tests in which the "quarters" were milked separately and the milk from each quarter collected in fractions show that whereas in the case of the first quarter milked there is a tendency for the percentage of fat in the milk to rise steadily from the earliest drawn to the last drawn fractions, this tendency is much less pronounced in the case of the other quarters. In the quarter milked last the tendency for a considerable portion of the milking is for the percentage of fat to fall rather than to rise. In all cases there is a very rapid rise in the percentage of fat toward the close of milking.

Taking the produce of each quarter as a whole, in 34 out of 37 comparisons of first quarters milked singly, the first quarters gave richer milk than the last quarters. In 95 tests in which the quarters were milked in pairs the first pair milked gave the richer milk on 65 occasions. Very quick milking as compared with very slow milking showed a difference of 10 per cent in milk yield and 40 per cent in fat yield in favor of quick milking. A comparison of ordinary milking, taking the teats in pairs, and simultaneous milking by two milkers of all four quarters showed a difference of 2 per cent in milk yield and 6 per cent in fat yield in favor of the latter method.

**Iowa educational market milk contest**, B. W. HAMMER and A. J. HAUSER (*Iowa Sta. Circ.* 30 (1916), pp. 4).—The results are given of two market milk contests that have been held by the dairy department of the Iowa College.

**Safeguarding nature's most valuable food—milk**, C. E. NORTH (*Vet. Jour.* 72 (1916), No. 496, pp. 329-339).—This article, which was prepared for the New York Milk Committee, deals briefly with the food value of milk, the milk industry in the United States, clean milk, clarification, pasteurization, certified milk, selection of milk for home use, and municipal milk control.

The cost of milk production, J. MACKINTOSH (*Jour. Bd. Agr. [London], Sup. 16 (1916), Sept., pp. 53-71*).—In this paper on the cost of milk production in England the attempt is made to evaluate the average cost of feed, various overhead and transit charges, interest on capital, and keep of the bull. In connection with feed costs credits have been given for manurial residues. The figures obtained relate to pre-war conditions. The investigations reported were carried on in only a few of the western counties of England, though brief references are given to other counties. The farms studied were divided as follows: Class 1, suburban farms; class 2, farms averaging 85 per cent grass land and 15 per cent arable land; class 3, farms averaging 66 per cent grass land and 34 per cent arable land; and class 4, farms chiefly arable lands. Only a few forms of the fourth type were studied, and the results obtained are not included in this paper.

The following table summarizes the averages obtained in 1914-15 on three of these type of farms:

*Summary of cost of production per 100 lbs. of milk.*

Type of farm.	Feed (gross cost).	Manurial residue.	Feed (net cost).	Overhead charges.	Transit charges.	Total cost.	Average yearly pro- duction per cow.
	<i>Pence.</i>	<i>Pence.</i>	<i>Pence.</i>	<i>Pence.</i>	<i>Pence.</i>	<i>Pence.</i>	<i>Gallons.</i>
Class 1.....	46.89	3.40	43.49	39.59	2.04	85.12	650
Class 2.....	36.11	2.52	33.59	24.45	14.37	72.41	640
Class 3.....	40.19	3.69	36.50	30.08	11.65	78.23	660

Some aspects of the dairying industry of England and Wales, W. GAVIN (*Jour. Bd. Agr. [London], Sup. 16 (1916), Sept., pp. 5-52, figs. 4*).—This paper deals with the development of the dairy industry of England and Wales in recent years; the share taken in the industry by different districts; the conditions obtaining in the different counties; the milk traffic of the various railway companies, with special reference to the London milk trade; the production and consumption of milk, both per capita and for the country as a whole; and the foreign trade in dairy produce.

The number of dairy cows and heifers in England and Wales increased from an average of 1,952,648 in 1881-1885 to 2,484,220 in 1914. Reckoning the average annual milk yield of cows in England at 582 gal. and in Wales at 425 gal. the estimated milk yield for 1915 is 1,070,000,000 gal. The annual consumption of milk per head of population is estimated at 15 gal. for London and 22.25 gal. for England and Wales. Statistics of London's milk trade are tabulated, and a review is given of the outstanding features of each of the principal producing areas.

The marketing of Wisconsin butter, B. H. HIBBARD and A. HOBSON (*Wisconsin Sta. Bul. 270 (1916), pp. 69, figs. 21*).—A survey in cooperation with the Office of Markets and Rural Organization of the U. S. Department of Agriculture is reported.

In discussing the butter industry of Wisconsin it is pointed out that the making of butter on the farm in the State is decidedly on the decline, while the increase in creamery butter making for the past few decades has been phenomenal. Wisconsin has very few centralizers.

The formation, management, and operation of cooperative and independent or private creameries are discussed in detail. Data reported on the marketing of butter show that about 4 per cent of the annual production of the State

is sold to creamery patrons, 15 per cent is sold locally, and about 80 per cent is shipped. About two-thirds of the butter shipped from Wisconsin is marketed in Chicago, Philadelphia, New York, and Boston. The remainder goes direct to at least 10 other States. Of 136 creameries 106 sell on prices fixed by the Elgin board of trade, 25 on the Chicago basis, and 5 on the basis of New York prices.

The average shrinkage of 160 tubs in 5.77 days in 18 shipments of butter from Wisconsin to Chicago was 0.399 lb. per tub. The average loss to the creamery through market methods of weighing was 0.549 lb. per tub. The average loss due to shrinkage of 46 tubs of butter shipped from Wisconsin to New York was 0.418 lb. per tub. These shipments averaged 7.7 days from creamery to market and were held at the creamery an average of 49 hours. The effect of storage on the price of butter is discussed.

Of 258 farmers giving reasons for making dairy butter instead of patronizing the creamery 24.42 per cent reported that the former is more profitable, 37.2 per cent objected to the disadvantages in hauling milk, 5.04 per cent were dissatisfied with the creamery, 16.63 per cent on account of more and better by-products, 8.54 per cent had no milk market, and 8.17 per cent made butter for family use and sold the surplus. The average prices per pound received by farmers for dairy butter in 1914 were 30.8 cts. in winter, 27.7 cts. in spring, 25.5 cts. in summer, and 28.7 cts. in fall. One-half of the dairy butter is sold direct from producer to consumer and the remainder largely to grocers and retail merchants. Of 583,000 lbs. of dairy butter handled by about 400 merchants 104,000 lbs. were sold to wholesale butter houses and renovators, the remainder being sold at retail. The demand for farm-made butter is said to be weakening.

In order to ascertain the relation of quality to retail price 94 samples of butter were purchased from as many different retail merchants in Chicago, care being taken to select samples that would be representative of the quality of butter consumed in that city. Fifty-six of these samples were in the form of prints, including 24 brands, and 38 samples were in the bulk. The butter was scored by an expert butter judge. It ranged in quality from 82 to 92 points, with an average of 88.3, and in price from 28 to 40 cts. a pound. Although the quality of the bulk and print butter was the same the former sold at an average of 34.2 cts. and the latter 36.8 cts. a pound. It was found that there was no marked relationship between quality and price of these samples. Where the samples scored 85 or less the price was lower, but higher prices were charged for some butter scoring 86 than for that scoring 92. In order to test this relationship further, 117 Chicago retail stores were visited in April and May, 1915, and information as to quality, dealer's margin, and price to the consumer was secured for 271 samples of butter and 54 samples of oleomargarine. The retailers' margin and the prices to the consumer varied as much between lots of the same grade as between butter of the poorer and better grades. The average price of extra butter to the consumer was 0.9 ct. less than that of firsts and extra firsts, and that of extra firsts was 0.1 ct. less than that of firsts. The retailer's average price for seconds was 2 cts. less than firsts. The retailer's margin on oleomargarine was larger than on all the grades of butter. Approximately 75 per cent of the butter was in the form of cartoned prints.

Brief notes are given on how butter quotations are made by the Elgin board of trade and by the Chicago market.

At the time of this investigation butter was selling at an average retail price of 34.55 cts. a pound. Based on returns from cooperative creameries, the farmer was getting 23.33 cts. or 67.7 per cent of this amount, the remainder being distributed as follows: Cost of hauling the cream to the creamery and the

butter to the railway station 1.5 cts., cost of manufacturing butter, including container, 2.33 cts., railway transportation 0.8 ct., storage 0.18 ct., shrinkage 0.23 ct., wholesale agents, including receivers, jobbers, brokers, etc., 1.75 cts., packaging 1 ct., and retailer 3.43 cts. a pound.

**Experiments on the preparation of homemade rennet, A. TODD and ELFRIDA C. V. CORNISH** (*Jour. Bd. Agr. [London], 23 (1916), No. 6, pp. 549-555*).—Experiments are reported on the home preparation of rennet from both fresh and dried stomach membranes of calves.

Rennet prepared from dried vells was of no practical value. Fresh vells of from 3 to 4 months-old calves and from young milk-fed calves produced an extract with fairly strong coagulating properties. With the addition of a preservative the rennet kept in good condition for six weeks and was then still active. The method of making the rennet is described. When used for cheese making in about double the quantity of commercial extract this rennet gave a very firm curd in a reasonable time.

**The improved system of selling cheese, J. L. SAMMIS** (*Hoard's Dairyman, 52 (1916), No. 15, pp. 511, 512*).—Some of the faults of the "cheese board" system of selling cheese are pointed out, and a description is given of the Quebec system of inspection and classification of cheese before sale. The author states that by this system, which is used by the Quebec Cooperative Society, many of the objections to the cheese board have been overcome.

## VETERINARY MEDICINE.

**Outline of lectures in special pathology, S. H. BURNETT** (*Ithaca, N. Y.: Carpenter & Co., 1916, pp. 65*).—This guide consists of an outline of lectures given by the author at the New York State Veterinary College at Ithaca.

Annual reports of proceedings under the diseases of animals acts, the markets and fairs (weighing of cattle) acts, etc., for the years 1911, 1912, 1913, and 1914 (*Bd. Agr. and Fisheries [London], [Vet. Dept.], Ann. Rpts. Proc., 1911, pp. 119, pls. 2; 1912, pp. 117, pls. 2; 1913, pp. 110; 1914, pp. 102*).—These consist in the main part of reports of the assistant secretary of the animals division. A. W. Anstruther, with accounts of the occurrence of foot-and-mouth disease, hog cholera (swine fever), glanders, anthrax, sheep scab, parasitic mange, etc. The 1911 report also contains the report of the chief veterinary officer, S. Stockman. Plates showing the occurrence of hog cholera and sheep scab for 1909 to 1912, inclusive, are included.

Various statistical data on the occurrence of diseases, international trade in animals, etc., are presented in the appendixes.

**Annual report for 1915 of the principal of the Royal Veterinary College, J. MCFADYEAN** (*Jour. Roy. Agr. Soc. England, 76 (1915), pp. 286-298, figs. 6*).—This is the usual annual report dealing with the occurrence of and work with anthrax, glanders, sheep scab, swine fever, and foot-and-mouth disease. The different methods of testing with tuberculin are also considered at some length.

**The Pharmacopœia of the United States of America (Philadelphia: P. Blakiston's Son & Co., 1916, 9. ed., pp. LXXX+728)**.—This ninth decennial revision, prepared by authority of the United States Pharmacopœial Convention, is official from September 1, 1916.

**The National Formulary (Philadelphia: Amer. Pharm. Assoc., 1916, 4. ed., pp. XL+394)**.—This fourth edition, prepared by the Committee on National Formulary of the American Pharmaceutical Association, is official from September 1, 1916.

**Magnesium hypochlorite in surgery**, M. DUBARD (*Bul. Acad. Méd. [Paris]*, 76 (1916), No. 33, pp. 134-136; *abs. in Jour. Amer. Med. Assoc.*, 67 (1916), No. 15, p. 1118).—A 1 to 2.5 per cent solution of magnesium hypochlorite was found to be absolutely harmless, while its bactericidal power was considerable and its preparation simple and inexpensive. As a disinfectant for the wounded in the European War it has proved superior to any others, including Dakin's fluid.

**The standardization of disinfectants**.—A critical comparison of the Hygienic Laboratory and Rideal-Walker tests, J. T. A. WALKER (*N. Y. Med. Jour.*, 103 (1916), No. 11, pp. 500-505).—From a general consideration of the various features of the two methods the author considers the Rideal-Walker method to be superior to the Hygienic Laboratory method in every respect.

**A method of anaerobic plating permitting observation of growth**, H. M. JONES (*Jour. Bact.*, 1 (1916), No. 3, pp. 339-341, fig. 1).—The construction of a simple apparatus, which consists of one-half of a Petri dish sealed with paraffin on a square stone or metal base provided with an inlet for the inert gas and an outlet for the displaced gas, and its manipulation are described in detail.

**A comparative study of colon bacilli isolated from horse, cow, and man**, T. J. MURRAY (*Jour. Infect. Diseases*, 19 (1916), No. 2, pp. 161-174, figs. 2).—“On an average the different types of strains, human, bovine, and equine, exhibit a remarkable similarity in all reactions tested, chiefly in acid production. One remarkable exception was the ability of 24 strains of bovine colon bacilli to produce acid in inulin media. The other differences were not marked enough to be of value.”

**An experimental investigation into the rôle of the blood fluids in the intracellular digestion of certain bacteria and red blood corpuscles**, S. R. DOUGLAS (*Proc. Roy. Soc. [London]*, Ser. B, 89 (1916), No. B 617, pp. 335-341).—Experiments are reported in detail, the results of which show that the blood fluids have the property of influencing the digestion of such bodies as red corpuscles and bacteria taken up by the leucocytes. The action of the blood fluids is quite independent of the opsonic action, since the intracellular digestion may be more marked as the result of the action of a serum of low opsonic power than that of a serum of a much higher opsonic power.

“The power of the blood fluids to prepare such bodies as red blood cells or bacteria for digestion by solutions such as trypsin and leucoprotease, or by the digestive fluids which are secreted after such bodies are ingested by the leucocytes, is not . . . due to stimulation of or an action on the leucocytes, but is due to a direct action on the bacteria, or, as the case may be, the red blood corpuscles. This is demonstrated by experiments in which the red blood corpuscles or bacteria, after being brought in contact with fresh serum, which was subsequently removed, were found to be digested by solutions of trypsin or leucoprotease, solutions which had been previously shown to be quite without action.” This property of the serum is destroyed by heating to 60° C. The name “protryptic” has been proposed for this property of the serum, as it appears to prepare such bodies as red corpuscles and bacteria for solution by the digestive fluids secreted by the leucocytes or by solutions of trypsin.

**The permeability of the gastro-intestinal wall to infection with *Sporothrix schenckii***, D. J. DAVIS (*Jour. Infect. Diseases*, 19 (1916), No. 5, pp. 688-693).—The work reported indicates that white rats fed at intervals of a few days with large quantities of cultures of *S. schenckii* may become infected. The infection tends to localize in the mesentery, peritoneum, and spleen. The organisms also appear to penetrate the normal mucosa of the intestinal tract. No active or healed lesions were visible in the mucosa or in the wall of the stomach or intestines.

A laboratory infection caused by a bovine strain of *Bacillus enteritidis*, K. F. MEYER (*Jour. Infect. Diseases*, 19 (1916), No. 5, pp. 700-707).—Clinical, bacteriological, and serological findings of a case of accidental infection by handling a bottle of sterilized milk which had been artificially contaminated with a culture of *B. enteritidis* is reported. It is indicated that "a recently isolated strain of *B. enteritidis* pathogenic for animals may differ from a strain pathogenic for man in its inability to be coagglutinated by paratyphoid or suipestifer sera."

The antibodies of spores, G. CHIMERA (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 39 (1916), No. 16, pp. 479-487).—From the studies reported it is concluded that there is no evidence that specific agglutinins are liberated by the organism after inoculation of spores (*Bacillus anthracis*, *B. subtilis*), at least not within ten days after the inoculation. The agglutinins produced by the presence of bacilli have no action on the spores of the respective organisms.

The serological data are submitted in tabular form.

The precipitin reaction with silkworm caterpillar immune serum, K. AOKI (*Bul. Imp. Sericult. Expt. Sta. Japan*, 1 (1916), No. 1, pp. 53-81).—The results of the investigation reported show that silkworm caterpillars can be easily differentiated from closely related insects by the precipitin reaction. The reaction can further be used to classify various closely and distantly related animal species so that they can be definitely placed in their proper zoological position.

The precipitin titer of the immune serum was found not to be equally high in all the sera of animals of the same species, especially if the serum came from an animal that was in the second, third, or fourth stage of development. In this case a lower precipitin value was given than would have been yielded by adult specimens or the pressed juice of the eggs. The silk glands of *Bombyx mori* show a strong organ specificity. No difference in the precipitant power of the sera of the two sexes of the silkworm caterpillars was observed. The data are presented in tabular form and discussed in some detail.

The application of the agglutinin reaction in the bacteriological examination of silkworms.—On the question of the identity of *Bacillus sotto* (Ishiwata), *B. alvei* (Cheshire and Cheyne), and *B. megaterium*, K. AOKI and Y. CHIGASAKI (*Bul. Imp. Sericult. Expt. Sta. Japan*, 1 (1916), No. 1, pp. 83-95).—Tabular serological data are reported which indicate that the agglutination reaction is strongly specific in the case of *B. sotto*. This organism can be easily differentiated from *B. megaterium* and *B. alvei* by this reaction, so that the question of its identity with the latter organisms can be discarded.

The biologic reactions of the vegetable proteins.—VIII, The specificity of the Abderhalden reaction with vegetable proteins, O. J. ELSSENER (*Jour. Infect. Diseases*, 19 (1916), No. 5, pp. 655-681).—The work reported demonstrates that "the specificity of the Abderhalden reaction (dialysis method) in experimental animals (rabbits) immunized with pure isolated vegetable proteins is far from being absolute. . . . Under the conditions of the experiments the Abderhalden reaction is at best only quantitatively specific and even this quantitative specificity is not always exhibited. This is demonstrated by the following observations: (1) An homologous substrate may react specifically with its immune serum, no other protein reacting; (2) it may vary quantitatively in the degree of interaction with its own immune serum; (3) it may react with its immune serum but no more strongly than do the heterologous substrates tried against the same immune serum; (4) it may give no reaction against its immune serum, while other heterologous proteins may react strongly against this serum; (5) it may react at times more strongly with a

heterologous immune serum than with its own immune serum. However, there is an obvious tendency for a substrate to react more often and yield stronger reactions when tested against its homologous immune serum than when tested against a heterologous immune serum."

In comparing the Abderhalden test and the anaphylactic test (E. S. R., 35, p. 679) with the pure vegetable proteins it was found that the results present certain resemblances and also some very definite differences. "In either reaction the more closely the proteins are allied chemically and physically the less specific the reactions tend to become. On the whole, however, the results obtained by anaphylaxis are much more constant and specific."

**Experiments with the Abderhalden dialysis procedure, R. OTTO and G. BLUMENTHAL** (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 24 (1915), No. 1, pp. 12-41, figs. 3).—Detailed experimental data of the examination of the sera from pregnant individuals and from individuals afflicted with dementia præcox are reported.

The results show that sera from pregnant individuals almost invariably cleaved placental tissue. A positive reaction, however, is deemed only of limited diagnostic value, since other sera, especially those from carcinomatous individuals, give a positive reaction with ninhydrin after digestion with placental substrate. A negative reaction, however, may safely be taken to indicate the absence of pregnancy. The sera of dementia præcox patients (males) yield a positive reaction fairly regularly with testes, often with brain, and occasionally with placenta as substrate. Testes substrate is cleaved by the sera of patients suffering from other diseases, and also by the sera of pregnant individuals. The positive reaction with testes substrate is therefore also only of very limited diagnostic value, especially in differential diagnosis.

It is concluded that the dialysis procedure is not to be recommended for general practice because of the many sources of error in its manipulation. A bibliography of 28 references cited is included.

**The complement content of Eck-fistula dogs, N. P. SHERWOOD, C. SMITH, and R. WEST** (*Jour. Infect. Diseases*, 19 (1916), No. 5, pp. 682-687, fig. 1).—"The complement content of normal dog serum may vary in the same animal from  $\frac{1}{4}$  to  $\frac{1}{2}$  that of guinea pig serum. Immediately following the establishment of Eck's fistula there is a temporary drop in complement, lasting not more than 16 hours as a rule. There is a much greater drop in complement under chloroform anesthesia than under ether anesthesia. The return to normal is apparently just as rapid when only sufficient chloroform is used to produce the surgical anesthesia. The complement content of dog serum following the establishment of Eck's fistula was normal within from 6 to 16 hours after the operation and remained normal for at least 90 days (last observation) in the dogs studied.

"There is no corresponding drop in complement paralleling or accompanying the degeneration of the liver. There does not seem to be sufficient evidence, as yet, to warrant the assumption that the liver plays a more important rôle in the production of complement than do other organs or tissues of the body."

**A cutaneous reaction in canine distemper, J. A. KOLMER, M. J. HARKINS, and J. REICHEL** (*Jour. Immunol.*, 1 (1916), No. 5, pp. 501-510).—The authors have prepared from a number of strains of *Bacillus bronchisepticus* (Ferry-McGowan) an antigen for use in anaphylactic tests for which the name "bronchisepticin" is proposed. Experimental data submitted indicate that the highest percentage of positive reactions occurred among animals having an acute case of the disease at the time the tests were made (77 per cent) and among those known to have had distemper while under observation (60 per

cent). In animals that presented no positive clinical evidences of the disease 35 per cent of the reactions were positive. The previous history of these animals, however, was unknown.

It is indicated that, while the "skin test may prove of practical value in the diagnosis of canine distemper and particularly as an index of a previous infection in an apparently normal animal, it is probable that it has no value as an index of immunity and that an animal presenting a positive reaction is still susceptible to relapses or recurrences of the disease."

Anaphylactic skin reactions in relation to immunity.—IV, The relation of the bronchisepticin skin reaction to immunity in canine distemper including the bactericidal action of dog serum for *Bacillus bronchisepticus*, J. A. KOLMER, T. MATSUNAMI, and M. J. HARKINS (*Jour. Immunol.*, 1 (1916), No. 5, pp. 571-584).—Further anaphylactic skin tests indicate that a large percentage of dogs are hypersensitive to the protein of *B. bronchisepticus* and that the reactions are probably specific.

The sera of normal animals, those suffering with the disease, and those convalescent from the infection were found to possess very little or no bactericidal activity over the micro-organism as measured by tests in vitro. It is indicated that dogs yielding positive bronchisepticin reactions are still susceptible to canine distemper.

A contribution to the study of the changes in the blood count in dourine, N. POPESCO (*Abs. in Jour. Amer. Vet. Med. Assoc.*, 48 (1916), No. 4, pp. 469, 470).—A report of studies made while in search of a method of early diagnosis.

The virulence of the blood of animals affected with foot-and-mouth disease, G. COSCO and A. AGUZZI (*Policlin.*, *Sez. Prat.*, 23 (1916), No. 18, pp. 551, 552; *abs. in Jour. Amer. Med. Assoc.*, 66 (1916), No. 24, p. 1895).—During the course of investigations made under the auspices of the National Public Health Service of Italy the blood of 116 cattle was found virulent during the entire febrile course of the disease, as virulent as the contents of the vesicles. The red corpuscles and the serum seem to be equally virulent and the defibrinated blood kept on ice retained its virulence for over a month. Erythrocytes thoroughly rinsed from all traces of serum, and the serum alone, reproduced the diseases on subcutaneous injection of other cattle with a dose as small as 1 cc. The authors consider the erythrocytes to be ideally adapted for the production of vaccine and are working along this line.

The K. H. reaction in glanders, J. KRANICH and W. KLIEM (*Ztschr. Veterinärk.*, 27 (1915), No. 10, pp. 289-296).—A modified technique for the K. H. reaction of Pfeiler and Scheyer (*E. S. R.*, 34, p. 276), which consists of complement deviation and hemagglutination, is described in detail. The system used is composed of horse serum as complement, bovine serum as amboceptor, guinea pig corpuscles as hemolytic antigen, the glanders bacillus, and the serum to be examined.

The procedure is deemed to yield excellent results and is highly recommended. The name hemagglutination reaction is proposed in place of K. H. reaction.

John's disease, J. M'FADYEAN and A. L. SHEATHER (*Jour. Compar. Path. and Ther.*, 29 (1916), No. 1, pp. 62-94).—Reports are given upon the experimental transmission of the disease to cattle, sheep, and goats, with notes regarding the occurrence of natural cases in sheep and goats. The facts here recorded suggest that among sheep the disease may have a wider distribution than has heretofore been suspected.

Milk in relation to Mediterranean fever, C. PORCHER and P. GODARD (*Le Lait et la Fièvre Méditerranéenne. Paris: Asselin & Houzeau, 1916, pp. 114, pls. 4, figs. 3*).—This is a contribution to the study of the rôle which milk plays

in the etiology and spread of Mediterranean or Malta fever, including a review of the literature pertaining to this disease. The subject is treated under the following headings: The history and dispersion of Malta fever; the appearance, culture, and vitality of *Micrococcus melitensis*; symptoms, diagnosis, and prophylaxis of Malta fever; the infection of goats with *M. melitensis*; the relation of goat's milk and cheese to Malta fever in man; and the detection of unhygienic milk by chemical analysis.

It is concluded that Malta fever is transmitted to man almost wholly by drinking raw milk from infected goats or by eating curd or cheese made from goat's milk. In infested districts goat's milk should not be used unless it has been boiled and cheese from goat's milk should not be eaten unless it is very old.

**Hereditary transmission of rabies**, D. KONRADI (*Ann. Inst. Pasteur*, 30 (1916), No. 1, pp. 33-48; *abs. in Amer. Jour. Vet. Med.*, 11 (1916), No. 10, pp. 808, 809).—The author concludes in this paper, continuing previous work (E. S. R., 20, p. 279), that with dogs, rabbits, guinea pigs, and probably other animals the rabies virus is transmitted from mother to fetus, but its virulence gradually diminishes. See also other notes (E. S. R., 22, pp. 587, 682).

**A modification of the Hygienic Laboratory method for the production of tetanus toxin**, HARRIET L. WILCOX (*Jour. Bact.*, 1 (1916), No. 3, pp. 333-338).—A method essentially the same as that used at the Hygienic Laboratory of the U. S. Public Health Service,<sup>1</sup> with a few slight variations, is described in detail.

**A new culture medium for the tubercle bacillus**, W. W. WILLIAMS and W. BURDICK (*Jour. Bact.*, 1 (1916), No. 4, pp. 411-414).—The preparation of an egg-meat infusion culture medium containing gentian violet as an inhibitor of the growth of contaminating micro-organisms is described in detail. A method of isolating tubercle bacilli from sputum is also described.

**The combined and follow-up systems of tuberculin testing**, G. H. HART and J. TRAUM (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 2, pp. 189-214).—This is a general discussion of the subject, together with some experimental data from which it is concluded that tuberculous animals, while giving negative results to one form of tuberculin application, may give positive reactions to another form. The value of combining two or more tests and following with further tests several weeks later on all nonreacting animals is deemed evident. The value of the follow-up test is to detect animals in the incubation stage or those which were insensitive to tuberculin for other reasons at the time of the previous test. The ophthalmic test, together with an intradermal injection, is considered to be a very satisfactory combination.

**Studies in infectious abortion in cattle**, W. GILTNER, E. T. HALLMAN, and L. H. COOLEIDGE (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 3, pp. 320-339).—This article contains tabulated serological data obtained in a comparison of the complement fixation with the agglutination test for contagious abortion, together with temperature charts of nonpregnant animals which had received two injections of living organisms and of pregnant animals receiving injections of dead organisms.

From comparative data it appears that the complement fixation test will indicate more reactors than the agglutination test. However, animals were found to react to the agglutination test and not to the complement fixation test.

The material by Cooleidge previously noted (E. S. R., 34, p. 679) is also included.

<sup>1</sup>Jour. Med. Research, 33 (1915), No. 2, pp. 239-241.

A case of contagious broncho-pneumonia caused by *Bacillus coli communis*, E. M. STANTON (*Vet. Jour.*, 72 (1916), No. 490, pp. 138, 139).—In an outbreak of this disease in Massachusetts in which some 40 young calves succumbed *B. coli communis* appeared to be the causative agent.

The use of arrhenal for the treatment of Texas fever, J. E. AGHION (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 2, pp. 227, 228).—The successful use of arrhenal (disodium-methyl arsenate) in several cases of Texas fever in cattle in Egypt is reported.

Further studies on hog cholera with reference to *Spirochæta hyos*, W. E. KING and R. H. DRAKE (*Jour. Amer. Vet. Med. Assoc.*, 50 (1916), No. 2, pp. 168-188, figs. 6).—Inoculation experiments with several strains of virus are reported and the results discussed in some detail.

It is concluded in general that in order to prove with certainty the direct etiological relation of *S. hyos* to hog cholera "some means must be developed through which the organism may be isolated in pure culture directly from the infected animal in order that pure cultures, unattenuated by tedious manipulation in an artificial environment, may be utilized in a series of animal inoculation experiments. Under such conditions uniformly positive results, together with data already in hand, would serve as final, conclusive evidence as to the specific pathogenicity of *S. hyos*."

It is indicated that until such experiments can be successfully carried out positive conclusions must be withheld. *S. hyos*, however, is regarded as an organism present in animals infected with hog cholera, possessing certain characteristics suggestive of its pathogenic nature.

Illinois hog cholera serum plant (*Breeder's Gaz.*, 70 (1916), No. 20, pp. 929, 930, figs. 4).—This is a description of the equipment and methods employed in the manufacture of serum at the Illinois state hog cholera serum plant at Springfield.

Enterohepatitis or blackhead in turkeys, C. H. HIGGINS (*Canada Dept. Agr., Health Anim. Branch Bul.* 17 (1915), pp. 11, pls. 5).—A general account of this disease, together with an account of the prevention of blackhead by the biological laboratory method of artificial incubation and isolation.

Enterohepatitis or blackhead and the biological laboratory system of raising turkeys, C. H. HIGGINS (*Canada Dept. Agr., Health Anim. Branch Bul.* 19 (1916), pp. 6).—The information given in this bulletin supplements that noted above and outlines the biological laboratory system of raising turkeys.

## RURAL ENGINEERING.

Proceedings of the Ohio Engineering Society, thirty-seventh annual meeting held February 9, 10, 11, 1916 (*Proc. Ohio Engin. Soc.*, 37 (1916), pp. 189, figs. 5).—These proceedings contain among others the following special articles: Road Legislation, by C. C. Cass; The Need of Drainage Legislation, by C. L. Bushey; The Monolithic Construction of Brick Pavements, by M. B. Greenough; The Concrete Roads of Lake County, by H. P. Cumings; Construction of Bituminous Macadam Roads by the Penetration Method, by H. B. Stone; and Paints for the Protection of Steel Bridges, by J. H. Vance.

Laws of the State of Idaho relative to public waters, water rights, and irrigation, compiled by A. C. HINDMAN (*Boise, Idaho: Idaho Irrig. and Drainage Code Com.*, 1915, pp. 303).—The text of the laws is given.

Run-off and mean flow of some Texas streams, T. U. TAYLOR (*Bul. Univ. Tex.*, No. 65 (1915), pp. 25, figs. 10).—Measurements of flow made since 1896 on the Colorado River at Austin and Columbus, Tex., on the Brazos River at

Waco, Tex., and on the Trinity River at Dallas and Riverside, Tex., are reported in tabular and graphic form.

**Warner Valley and White River Projects**, J. T. WHISTLER and J. H. LEWIS (*Oreg. Cooper. Work. Dept. Int. U. S. Reclam. Serv., 1916, Feb., pp. 123, pls. 4, fig. 1*).—This report was prepared in cooperation with the State of Oregon.

The development proposed by the Warner Valley Project is the drainage of 46,000 acres of swamp land in Warner Valley, the irrigation of 33,000 acres of these lands in the south end by gravity canals, and pumping to irrigate 27,000 acres in the north end. Among the features specially referred to are the development of 2,000 electrical horsepower on Deep Creek for operating dredges during construction and to furnish power to four pumping plants in North Warner Valley on the completion of the project, and the provision for ample storage in Big Valley and Coleman Valley to insure the reclamation of the marsh lands in years of extreme run-off. The probable cost of this development as outlined is estimated at \$1,726,000, or about \$29 per acre. From the records of discharge for the streams entering Warner Valley for six years it is estimated that the mean annual run-off to the valley is 195,000 acre-feet, with a maximum of 308,000 acre-feet in the seasonal year 1910 and a minimum of 84,000 acre-feet in the seasonal year 1915. The extreme maximum run-off, it is stated, may reach nearly 600,000 acre-feet.

The White River Project is located to the south and east of the Oregon National Forest, in the vicinity of Mount Hood. "The drainage basin has an area of about 350 square miles and is largely forested in the upper regions of White River and tributary streams. . . . The mean annual run-off of White River near Tygh Valley for four years is about 234,000 acre-feet, the maximum occurring in the seasonal year 1911-12 with 297,000 and a minimum in 1914-15 with 163,000 acre-feet. . . .

"The soil, while shallow in places, is of fairly good quality and well adapted to irrigation. The percentage of waste land in the gross irrigable area is rather large, however, and the distributing system will, on this account, be more expensive. Drainage, which in some localities may be necessary, will not be difficult, as the topography of the region lends itself to an inexpensive system. . . . With an assumed duty of 1.5 acre-feet delivered to the land during the irrigation season, the plan of development includes (1) a storage reservoir in Clear Lake with a capacity of 18,000 acre-feet, furnishing 12,000 acre-feet net storage supply; (2) a diversion dam at the mouth of Boulder Creek; (3) two diversion canals, the one on the north being eight miles long with a capacity of 130 second-feet, to water approximately 13,000 acres, and the one on the south side of White River being ten miles long with a capacity of 230 second-feet, to water approximately 23,000 acres; (4) a distributing system for about 36,000 acres net.

"The apparent cost of this proposed development of 36,000 acres is \$36 per acre irrigated, including the purchase of the White River power plant."

**The saving of irrigation water in wheat growing**, A. and GABRIELLE L. C. HOWARD (*Fruit Expt. Sta. Quetta Bul. 4 (1915), pp. 14*).—This bulletin describes the soil, rainfall, temperature, and humidity of the Quetta Valley of India, describes the present methods of growing wheat, enumerates the principles underlying economy in the use of water in wheat growing, and reports experiments on water saving in wheat growing at Quetta.

The soil of the valley varies from brown to black in color and is of loessial origin. Flooding destroys its porosity and the surface is easily compacted. Wheat was grown on natural moisture only and with a single irrigation. Mulching was practiced as a water conservation measure in the first case and

only a thin crop was obtained, as much moisture was lost when it became impossible to continue the mulch. In the second case the land received one surface flooding after which it was cultivated by a spring tooth cultivator and leveled. The land was then sowed and a mulch maintained. The average yield of wheat was somewhat greater than the average yielded by similar unmanured land with six or seven irrigations.

"It is clear that as far as irrigated wheat growing is concerned, there is an enormous loss of water which might be profitably employed. The skillful use of the lever harrow after rain would also increase the yield of the unirrigated or dry crop wheat. Examined scientifically, the methods now in vogue are wasteful in the extreme both as regards the irrigation water and the winter rain and snow. To improve practice, two new implements are necessary—the spring-tine cultivator and a pair of lever harrows. . . . At a small cost, a very material increase in wheat production is possible in the Quetta Valley."

[Road laws] (*Montgomery, Ala.: State, 1916, pp. 16*).—This is a circular from the State Highway Department of Alabama to courts of county commissioners and boards of revenue of the counties of Alabama suggesting laws, rules, and regulations governing the working, maintenance, and preservation of the public roads.

Second report of the state engineer [of Arizona] to the state highway commission, L. COBB (*Rpt. State Engin. Ariz., 2 (1915-1916), pp. 673, pls. 3, figs. 118*).—This is a report of the work and expenditures of the state engineer's office on road and highway construction, maintenance, and repair in Arizona for the fiscal years 1915 and 1916.

The financial side of road improvement, B. K. COGHLAN (*Bul. Agr. and Mech. Col. Tex., 3. ser., 2 (1916), No. 8, pp. 22, figs. 6; rev. in Good Roads, 50 (1916), No. 19, p. 202*).—The author deals with the economics of road improvement, with special reference to conditions in Texas.

Demonstration roads at the Agricultural and Mechanical College of Texas, R. L. MORRISON (*Bul. Agr. and Mech. Col. Tex., 3. ser., 2 (1916), No. 1, pp. 20, figs. 15*).—Brief descriptions and specifications for sample roads, used as a part of the course of instruction in highway engineering at the Texas College, are given.

Earth roads, R. L. MORRISON (*Bul. Agr. and Mech. Col. Tex., 3. ser., 1 (1915), No. 2, pp. 20, figs. 14*).—This bulletin describes and illustrates the processes and machinery used in improving earth roads.

Gravel roads, B. K. COGHLAN (*Bul. Agr. and Mech. Col. Tex., 3. ser., 1 (1915), No. 8, pp. 16, pls. 4, figs. 4*).—This bulletin deals with the location, construction, and maintenance of gravel roads, with special reference to conditions in Texas.

Highway bridges and culverts, B. K. COGHLAN (*Bul. Agr. and Mech. Col. Tex., 3. ser., 1 (1915), No. 5, pp. 30, figs. 12*).—This bulletin deals with the important features of proper inspection, repairs, replacement, and maintenance of highway bridges and culverts and with the inspection of traffic as related to these.

Convict labor for road work, J. E. PENNYBACKER, H. S. FAIRBANK, and W. F. DRAPER (*U. S. Dept. Agr. Bul. 414 (1916), pp. 218, pls. 14, figs. 10*).—This report, prepared in cooperation with the U. S. Public Health Service, deals with "as nearly as possible all questions that might arise in connection with either the adoption of a policy relating to the use of convict labor in road work or the actual working out of such a policy. To this end a presentation and discussion of the principles involved, a digest of convict road laws, and a discussion of every phase of operation are embodied in the bulletin, together with specific detailed instructions for the carrying out of all recommendations."

Six systems of convict labor are described as "the lease, the contract, the piece-price, the public-account, the state-use, and the public-works-and-ways systems." The report embodies data obtained from personal visits made to convict camps and conferences held with state highway and prison officials in the States of New York, New Jersey, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, Texas, Michigan, Colorado, New Mexico, Arizona, Utah, Wyoming, California, Washington, and Oregon.

A special section is included on the character, preparation, and cost of food from data prepared by the Office of Home Economics of the States Relations Service. Other special sections on water supplies and camp sanitation are included, much of the substance of which has been noted in previous reports by Trullinger (E. S. R., 30, p. 690), Freeman (E. S. R., 34, p. 83), Lumsden, Stiles, and Freeman (E. S. R., 34, p. 88), and Cook, Hutchison, and Scales (E. S. R., 33, p. 455).

**Experimental studies of vacuum juice heaters, E. W. KERR and S. J. WEBER** (*Louisiana Stas. Bul. 159 (1916), pp. 46, figs. 20*).—Experiments on the operation of vacuum juice heaters, including the effect of air in steam, juice velocity, absolute pressure of the heating steam, tube materials, and the length of vapor path upon heat transmission, are reported. The experiments were made upon three different outfits, namely: (1) An especially designed small juice heater connected with a single effect evaporator in the engineering laboratory, (2) vacuum juice heaters connected to each body of the double effect at the Audobon Park sugar factory, and (3) the vapor juice heaters in connection with the quadruple effect at the Central Florida in Cuba. The first outfit was used strictly for research work, while the other two represented operation under regular factory conditions.

The laboratory experiments showed the marked effect of the presence of air in steam in reducing the coefficient of heat transmission. "This shows the necessity of properly venting vacuum juice heaters." The juice velocity was varied from a minimum of 131 ft. per minute to a maximum of 502 ft. per minute with corresponding variations in the coefficient of heat transmission of from 412 to 588. Tests made to compare the coefficients of heat transmission of copper and seamless cold-drawn steel tubes with vacuums of 0.0, 6, 13, and 18 in. and constant juice velocities gave average coefficients for copper and steel tubes of 576 and 280, respectively. The greater the vacuum the lower was the coefficient of heat transmission.

In the experiments with the second outfit, the effect of air richness in the heating vapor in decreasing the coefficient of heat transmission was shown. "It was found to be impossible to control the removal of air through the vents satisfactorily." Comparative studies of the effect of the use of juice and of water on heat transmission showed that the coefficients obtained with juice were considerably lower than those obtained with water. "The experiments brought out very clearly the importance of thorough venting of air and drainage of condensation. The difficulties encountered in relation to these two points emphasize the advantages, especially as regards the capacity, of taking the heating vapors from other than the last body of a multiple effect, even though the last body has the advantage in the matter of economy."

Tests on the general performance of the vacuum heaters in the third plant and on the effect of air in vapor showed that when provision was made for venting air the coefficients of heat transmission were much greater. Tests on the relation between air in steam and length of steam travel showed little increase in air richness for the first 15 ft., but thereafter the increase was

marked. Tests on the relation of juice temperature to juice travel showed that the temperature rise with distance of travel decreased in each successive heater. The curves of sharpest curvature corresponded to those with the highest coefficient and lowest air content and vice versa.

Tests of the power and steam consumption of sugar factories, E. W. KERR, W. A. ROLSTON, and S. J. WEBER (*Louisiana Stas. Bul. 158 (1916), pp. 45, pl. 1, figs. 6*).—Tests of the power and steam consumption of three sugar factories of 1,500, 4,500, and 1,000 tons daily cane handling capacity are reported. The power systems of the factories consisted, respectively, of centrifugal pumps, belt, and shafting; part electric motor and part direct steam drive; and all electric motor drive. The evaporating systems of the first two were plain quadruple effect and of the third quadruple effect and vapor juice heater.

The power consumptions per ton of cane per 24 hours were 0.65, 0.873, and 0.98 horsepower, respectively. The ratio of exhaust steam to total steam in the first plant was 0.4 and in the last 0.67. Considerable other data of tests are reported in tabular and graphic form.

Some experiments on pulling loads, with a discussion of the results, B. H. BROWN (*Walla Walla, Wash.: Author, 1916, pp. 16, figs. 6*).—This pamphlet reports several experiments "which have been made for the special purpose of measuring the pull in pounds exerted by horses as they move loads on the road and in the field."

In the hauling tests the roads selected were a macadam with a 0.4 per cent grade, a pavement with a 0.4 per cent grade, valley dirt with a 1.4 per cent grade, dirt wash from a hillside with a 3.1 per cent grade, a side of a hill with a 9.25 per cent grade, a brow of a hill with a 4.68 per cent grade, and a highland country road with a 1.44 per cent grade. Two wagons were used, the first having all four wheels of 3 ft. 6 in. diameter and a tire width of 3.25 in., and weighing, with two men, 1,950 lbs.; the second being a narrow-tire wagon, weighing, with two men, 1,705 lbs., with front wheels 3 ft. 9.5 in. in diameter, and hind wheels 4 ft. 7 in. in diameter. Both wagons were drawn empty and with loads of 2,020 and 4,040 lbs. both ways over the road on the same day.

It was found that the average force required to pull the wagons on the section of pavement was much less than that required for the macadam section. The average pull upgrade and downgrade on the pavement for a load of 4,040 lbs. on the narrow-tire wagon was less than 160 lbs. It required on the average a force of 70 lbs. to pull the empty wagon on the level pavement and 158 lbs. to pull the same wagon when loaded with a weight of 4,040 lbs. This means that for each additional ton of load an extra pull of 44 lbs. was enough to move the load on the pavement. "The pull up the 9.25 per cent grade, on the hillside dirt, was for the same load and wagon, 886 lbs. It required a force of 264 lbs. to pull the empty wagon up this grade. Taking this amount from the 886 lbs. for wagon and load leaves 622 lbs. as the extra pull required for the 2 tons of load, or an excess of 311 lbs. per ton up the grade. This is more than seven times as much per ton as that required on the pavement."

A comparison of the pull in the valley and on the highland showed "an unmistakable balance in favor of the highland road in the case of the wide-tire wagon, while with the narrow-tire wagon there was no great difference between them." An estimate of the horsepower used showed "that in every section except pavement the horses did more work per minute than the standard amount adopted for the horsepower. . . ."

"The tests showed that the heavy horses used in the tests were fully able to do the work generally accepted as a full horsepower for each horse. For a horse weighing only 1,000 lbs. the standard horsepower of 33,000 foot-pounds per minute would be too high, especially in the case of tandem teams or a

group of 30 or more horses drawing a combine. . . . Throughout the tests it was found that a 1,000-lb. pull for the two-horse team was a severe strain and could be sustained for only a few seconds at a time."

Tests made to measure the force required to pull the wagons over newly plowed ground and over tall wheat stubble gave the following results:

*Draft tests on plowed ground and stubble.*

Type of wagon.	How drawn.	Wagon empty.	1-ton load.	2-ton load.
On plowed ground:		<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Narrow-tire wagon.....	Straight ahead.....	284	808	1,300
Do.....	In a curve.....	444	910	1,612
Wide-tire wagon.....	Straight ahead.....	432	994	1,342
Do.....	In a curve.....	534	1,038	1,562
On stubble field:				
Narrow-tire wagon.....	Straight ahead.....		516	872
Do.....	In a curve.....	198	572	1,122
Wide-tire wagon.....	Straight ahead.....	264	520	1,018
Do.....	In a curve.....	310	608	1,216

"Some tests were made by starting loads in different ways to find the force required to start loads in ordinary practice. Out of 38 starts with the narrow tire wagon, empty and loaded, the average starting force was 2.6 times the average pull required to keep the wagon in motion after it had been started. The average for the wide-tire wagon, under the same conditions, was 2.9. . . .

"Some experiments were made to find out what could be done to lessen the extra pull at the time of starting loads. Out of many trials, the force required to start the wide-tire wagon slowly was found to be only 61 per cent of that required for the ordinary start in which the reins were gathered up and the load was supposed to move without delay. The force for an easy start, in the case of the narrow-tire wagon, was only 58 per cent of that required for the ordinary start. . . . The advantage of the slow start was fully demonstrated.

"The plan of starting a load with a pull sidewise is fairly effective on hard ground as it enables the team to get into motion slowly. In soft ground, however, when the front wheels are cramped to one side so that the hind wheels do not follow in their tracks, there is great disadvantage in breaking out the new wheel tracks."

The average results of tests of plow draft are given in the following table:

*Draft of plows.*

Kind of land.	Kind of plow.	Depth.	Number of horses.	Pull.
		<i>Inches.</i>		<i>Pounds.</i>
Hill.....	Two 14-in. gang.....	7	6	775
Field.....	One 14-in. walking.....	8	3	345
Bottom.....	One 12-in. walking.....	8	2	540
Bench.....	One 14-in. wheel.....	8	8	1,154
Field.....	One 16-in. wheel.....	11	6	750

"The pulls in pounds given in the table are averages of as many as 80 readings in some cases."

Second series of tests of mechanical cultivation, E. MARRE (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 37 (1916). No. 20, pp. 464-468).—Plowing tests on red clay soil and productive residual soil of a tractor having a 2 cylinder, 12-24

horsepower motor running at 400 to 750 revolutions per minute are reported. The grade of the red clay soil varied from nearly level to from 25 to 30 per cent.

The tractor was unable to pull a 3-bottom gang plow uphill effectively but pulled a 2-bottom plow both ways. The 3-bottom plow, covering a width of 1.05 meters (3.44 feet), was pulled downhill. In the residual soil with easy slope the tractor drew a double-bottom plow at a depth of 27 cm. (10.5 in.) and covered a width of 33 cm. Six oxen plowed the same width but only 25 cm. deep. The tractor plowed 1,056 square meters (0.26 acre) per hour and hauled a 16-toothed scarifier and a 3-piece harrow. It traveled twice as fast as oxen and it is considered to have replaced eight pairs of oxen and six men in the amount of work done.

Twenty-three liters (6 gal.) of petrol were burned in the engine in 2 $\frac{3}{4}$  hours, of which 1 $\frac{3}{4}$  hours were consumed in actual work and the other hour in stops and travel.

Plans and suggestions for the arrangement and construction of a modern milk house ([*New York*], *Borden's Condensed Milk Co.*, 1916, pp. 32, figs. 33).—Plans and descriptions of milk houses and ice houses for dairy farms are given.

Inexpensive plumbing for farm kitchens, W. A. ETHERTON (*Kans. Agr. Col. Ext. Bul. 9* (1916), pp. 23, figs. 7).—This bulletin describes plumbing systems for farm kitchens based on the method of using a force pump and three-way cocks described in a previous article (E. S. R., 35, p. 496).

The operation of a simple system of the type is described, showing how cold and hot water may be pumped and water siphoned from the hot water boiler to the sink or back to the cistern. A combination system using an attic tank or a pressure tank with this system is also described, together with fittings for shower baths, etc. A third section itemizes and explains the parts of the apparatus. A final section on cost, based on conditions in Kansas in April, 1916, is included.

The water supply of the farmhouse, J. D. WALTERS (*Kans. Agr. Col. Ext. Bul. 10* (1916), pp. 42, figs. 15).—This is a semipopular bulletin, based on Kansas conditions, containing sections on the following subjects related to farm water supplies: Amount of water required; spring water and well water; wells; contamination of wells; artesian wells; filtering the cistern water; pumps, lifts, and rams; power required to lift water; theoretical horsepower; the windmill; the water tank; the concrete reservoir; the water tower; the air-pressure tank; compressed air lifts; soft water for the laundry and the bathroom; the automatic water lift; the hydraulic ram; the friction element in plumbing; and cheap home ice.

Water supply systems for the farm home, H. W. RILEY (*Cornell Countryman*, 13 (1916), Nos. 7, pp. 566-569, figs. 3; 8, pp. 665-668, 690, 692, figs. 4).—A brief description of hydropneumatic and pneumatic tank water supplies is given, together with a discussion of the hydraulic principles involved in pumping and distributing water for small systems.

Sewage treatment in small communities without sewerage systems, P. HANSEN (*Univ. Ill. Bul.*, 13 (1916), No. 19, pp. 189-195, figs. 5).—Small sewage purification systems, consisting of settling tank and tile absorption areas of sufficient size to meet temporarily the requirements of small communities, are briefly described and illustrated.

## RURAL ECONOMICS.

Agricultural economics, E. G. NOURSE (*Chicago: Univ. Chicago Press. 1916, pp. XXV+896, figs. 23*).—"This volume represents an effort to carry over into agricultural economics some results of recent experience in the use of the dis-

cussion methods of teaching elementary and intermediate courses in economics. The book aims to bring together in an orderly arrangement (1) a store of information which may profitably come within the view of the student who desires to understand the economic phenomena of agriculture, and (2) a considerable number of opinions which have already been expressed as to the meaning of these facts."

The author has divided the contents into the following chapters: The emergence of the problem of agricultural economics; consumption; land and other natural agents of agricultural production; human effort as a factor in agricultural production; capital-goods as a factor in agricultural production; organization and management of the agricultural enterprise; records and accounts as measures of efficient management; principles of value and price as related to farm products; market methods and problems; transportation and storage facilities as factors in the marketing of farm products; the rent and value of farm land; land tenure and land policy; interest on farm loans; rural credits; agricultural wages; some problems of agricultural labor; and profits in agriculture.

The relationship of New England agriculture to manufacturing, K. L. BUTTERFIELD (*Trans. Nat. Assoc. Cotton Manfrs., No. 100 (1916), pp. 213-223*).—The author calls attention to the fact that agricultural products are in many instances the basic products in manufacturing industries and discusses the extent to which the farmers in New England can furnish such material. He also calls attention to the available products as they might influence the diet of the working men and their families and indirectly influence the efficiency of New England manufacturing industries.

Farm management studies in eastern Nebraska, H. C. FILLEY (*Nebraska Sta. Bul. 157 (1916), pp. 32, figs. 5*).—The author's conclusions are as follows:

"The 80-acre grain and stock farm of eastern Nebraska does not utilize man, horse, or machine labor as efficiently as do farms of a larger size. The family farm which provides work for approximately two men or the equivalent, seems to be the most profitable. On the farms surveyed, approximately half of the work, aside from that done by the operator, was performed by boys under 21.

"The best paying farms found in this survey had crop yields from 15 to 30 per cent better than the average of all farms, while of the farms whose yields were as much as 15 per cent below the average of their community, few gave satisfactory returns. The most profitable farms included in this survey sold two or three major products and from two to four minor products. Those selling but one or two products were not profitable as they did not furnish productive labor for a large enough part of the year.

"If 5 per cent interest is allowed upon all capital invested by the operator, owned farms returned an average labor income of \$203 and tenant farms an average of \$806 to the operator. The better showing made by the tenant farms is largely accounted for by the fact that they returned to the landlord only 3.5 per cent interest upon the land valuation, while the owner-operator is charged 5 per cent upon his valuation. The low rate of return is due primarily to the security of the investment. Owned farms in Richardson county contributed \$509, and tenant farms \$405 toward the farmers' living, in addition to the 'labor income.' This is somewhat above the average of farms covered by the survey.

"Placed upon the same basis as the city wage earner, with interest upon land figured at the landlord's rate of return, the average farmer of eastern Nebraska receives between \$1,000 and \$1,200 per year for his labor and management."

**Rural land ownership among the negroes of Virginia, S. T. BITTING** (*Charlottesville, Va.: Univ. Va., 1915, pp. 110, fig. 1*).—The author discusses the factors which influence the negroes in obtaining possession of the land and their success in developing the right types of farming. The discussion relates to conditions in Virginia in general, with special emphasis upon conditions found in Albemarle County.

**Facts about land** (*London: John Murray, 1916, pp. XVI+319*).—This report, prepared by the Land Agents' Society, discusses and criticizes the report of the Land Enquiry Committee (E. S. R., 30, p. 491).

**Farm work for discharged soldiers, H. E. MOORE** (*London: P. S. King & Son, Ltd., 1916, pp. 31*).—This publication contains proposals indicating the manner in which disabled or discharged soldiers may be assisted to secure a livelihood from agricultural work and suggests a method by which the State could aid that object.

**Rural cooperation in Denmark, G. DESBONS** (*La Coopération Rurale en Danemark. Montpellier: Fermin & Montane, 1916, pp. 178*).—The author discusses the development of cooperation in Denmark, the organization and functions of agricultural associations, the difficulties met, and the results accomplished.

**The result of an experiment in agricultural credit in Tuscany, F. VIRGILII** (*Atti R. Accad. Econ. Agr. Firenze, 5. ser., 12 (1915), No. 3-4, pp. 229-237*).—These pages contain a brief discussion of the results obtained in an agricultural bank established in 1913 in Tuscany.

**The report of the Agricultural Organization Society for the year ended March 31, 1916** (*Rpt. Agr. Organ. Soc. [London], 1916, pp. VIII+99*).—This report contains brief statements regarding the various activities of the society, with special reference to war conditions.

**[Report on the working of the cooperative credit societies], G. NATH** (*Rpt. Coop. Credit Soes. Ajmer-Merwara, 1916, pp. 15+[21]*).—This report sets forth the progress of the work in connection with the societies during the year, together with statements regarding the operations of the various agricultural banks.

**Second annual report of the department of foods and markets, 1915** (*Ann. Rpt. Dept. Foods and Markets, N. Y., 2 (1915), pp. 33*).—In this report are discussed the activities of the bureau in securing better market conditions, market facilities, and prices for farm products. Its efforts were principally devoted to the marketing of fruit, hay, live stock, and live stock products.

**Monthly crop report** (*U. S. Dept. Agr., Mo. Crop Rpt., 2 (1916), No. 11, pp. 109-120, fig. 1*).—Among the data in this report are a summary of farm prices, the estimated farm value of important products, the range of prices of agricultural products at important markets, and the estimated crop conditions November 1, 1916. It also includes special reports regarding the wheat supply and distribution per capita for a series of years, hop production and consumption, milk prices, the prices of turkeys, chickens, upland middling cotton at New Orleans, alfalfa, and clover seed, the damage to wheat due to black rust in North Dakota, South Dakota, and Minnesota, the wheat surplus and deficiency by States, index figures of total crop yields for a series of years, the potatoes moved from counties where grown and the quantities harvested by months, celery acreage, honey, pecan, and onion production, etc.

**Food and raw material requirements of the United Kingdom** (*London: Dominions Roy. Com., 1915, pp. IV+123*).—This report, prepared by the Royal Commission on the Natural Resources, Trade, and Legislation of Certain Portions of His Majesty's Dominions, indicates the requirements for the various food products, the sources of supply, and the quantities consumed for 1913-14 and previous years.

Prices and supplies of corn, live stock, and other agricultural produce in England and Wales, R. H. REW (*Bd. Agr. and Fisheries [London], Agr. Statis., 50 (1915), No. 3, pp. 103-151*).—This bulletin continues data previously noted (E. S. R., 34, p. 491), adding statistics for 1915.

Agricultural statistics of Ireland, with detailed report for the year 1914 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1914, pp. XXI+143*).—This report continues the information previously noted (E. S. R., 31, p. 895) by adding data for 1914, and contains a special report comparing the acreage devoted to crops, the number of live stock, and number of agricultural holdings as found in 1914, with a series of years extending back to 1867.

[Agricultural statistics for the Netherlands] (*Jaare. Konink. Nederlanden, Rijk Europa 1914, pp. 203-228*).—These pages continue information previously noted (E. S. R., 33, p. 894), adding data for 1914.

[Agricultural statistics in Switzerland] (*Statis. Jahrb. Schweiz, 24 (1915), pp. 74-82*).—These pages continue data previously noted (E. S. R., 35, p. 590).

A B C of Queensland statistics, 1916, compiled by N. J. MACLEOD (*Brisbane: Govt., 1916, pp. 42*).—This continues data previously noted (E. S. R., 34, p. 792).

[Agriculture in Ceylon] (*Ceylon Blue Book, 1915, pp. V 1-V 17*).—These pages of this volume contain data regarding the area, production, and prices of crops, number of live stock, and wages of agricultural labor by provinces and districts.

Agriculture in Portuguese Angola, D. TARUFFI (*Agr. Colon. [Italy], 10 (1916), No. 8-9, pp. 385-431, pls. 12*).—In this article are discussed the topography, climate, extent of agricultural development, types of crops, and live stock produced in this region.

International yearbook of agricultural legislation (*Inst. Internat. Agr. [Rome], Ann. Internat. Leg. Agr., 5 (1915), pp. XCII+1460*).—This volume continues the information previously noted (E. S. R., 34, p. 91) by adding the most recent laws and regulations.

## AGRICULTURAL EDUCATION.

The change of stress in making the curriculum from subject-matter to the individual, A. C. TRUE (*High School Quart. [Ga.], 4, (1916), No. 4, pp. 261-267*).—In the author's opinion, the general tendency to give all vocations the professional basis and attitude is reflected in secondary and higher educational institutions in the broadening of courses and the constantly increasing number of subjects taught, resulting in a demand for expert guidance and particularly for vocational guidance. This state of things is putting a tremendous burden, financially and morally, on both public and private schools and colleges.

"Studies in the science of pedagogy are bringing out facts regarding the development of the mind through childhood and adolescence, the actual conditions with reference to the effect of memory studies, observation, manual exercises, etc., on the student's mind as related to his inclinations, interests, and aptitudes. These studies show the great variety of factors which enter into the effective education of the individual and the reaction of the different factors on the peculiar type of mind which the individual is endowed with. Therefore, while there are certain things which all children should be taught there must be increasing differentiation of subject-matter and methods of instruction as the individual mind develops and becomes more definitely related to the world of nature and vocations in which the fully developed man or woman is to work."

The individual youth must choose the subjects that he will study and it is the duty of educational institutions to study the individual student and give

him the best advice they can on the basis of his make-up and requirements. "They ought not to hold him within the limitations of their own curriculum, which because of lack of means or of the aim of the institution may be very narrow."

It being impossible for any one school or college to teach everything, there is a growing tendency to put all education on a public foundation. The State or Nation, with the wealth at its command, can so arrange its educational institutions that taken together they will provide instruction in all subjects, except perhaps theology. Through scholarships or other means it can enable students to easily move about from one institution to another wherever located. To compete successfully with public institutions private schools will be more and more compelled to associative effort accompanied by individual differentiation. "There are many arguments in favor of colleges having from 500 to 1,000 students in undergraduate work. These usually can not cover a wide range of work, and the student should choose the college best adapted to his requirements. One thing is absolutely certain, that the attempt to run colleges on the narrow curriculum in vogue 50 years ago will be a complete failure, or if it has in some instances partial success it will be an injury to many of the students."

**Agriculture**, O. H. BENSON and G. H. BETTS (*Indianapolis: The Bobbs-Merrill Co., 1915* [16]+444+XI+[16], figs. 189).—The text for the farm previously noted (E. S. R., 33, p. 95) was also issued in the same year as a text for the school and farm, including in addition, at the end of the book, instructions to teachers on public school extension work, equipment, laboratory material, method of instruction, seasonal order of study, and reference material.

**Agriculture**, O. H. BENSON and G. H. BETTS (*Indianapolis: The Bobbs-Merrill Co., 1916*, pp. [16]+520+XIX, pl. 1, figs. 211).—The above text has also been adapted to Southern and Western conditions. Chapters have been added on Agriculture in the South, Agriculture in Western States, Farming Under Irrigation, Cotton, Tobacco Culture, Sugar Farming, Culture of Citrus, Fruits and Nuts in the South and West. The chapter on Home Canning of Fruits and Vegetables has been extended to include the canning of soups and the description of the five common methods of canning in use, canning equipment, tinning, capping, and soldering, repair work, etc.

**Introduction to agriculture: Practical studies in crop production**, C. M. WEED and W. E. RILEY (*Boston: D. C. Heath & Co., 1916*, pp. VI+268, figs. 131).—A chapter on Soils: Their Origin, Characteristics, and Improvements, has been added to this text, which has been previously noted (E. S. R., 32, p. 393).

**Elementary agriculture for Alberta schools**, J. McCAIG (*Toronto, Canada: W. J. Gage & Co., Ltd., pp. X+11-256, pls. 40, figs. 45*).—This elementary text for Alberta schools comprises five parts dealing respectively with the soil; the life cycle of the general plant; tillage, with particular reference to prairie agriculture; representative crops; types of farm enterprise; and types and breeds of farm animals. Each chapter includes practical exercises to be done in the school, home and school garden, and field.

**Agricultural education and research** (*Rpt. Bd. Agr. Scot., 4 (1915), pp. XIV-XIX*).—An account is given of the progress in 1915 in agricultural education and research work under the control of the Board of Agriculture of Scotland.

**A county scheme for training women for farm work**, R. N. DOWLING (*Jour. Bd. Agr. [London], 23 (1916), No. 4, pp. 349-353, pl. 1*).—The author describes a scheme of the Lindsey Education and War Agricultural committees for overcoming the prejudices against the employment of women in farm work

in areas of Lincolnshire other than in the South and North where women have been extensively employed in such work. A County Training and Clearing House Station accommodating 12 women at a time was organized at Elkington, near Louth, where free instruction extending on an average through two weeks is given in such subjects as weeding corn, hoeing roots, milking, hay making, etc. Wages are paid by the estate for work done that is of value to the farm which may more than cover the nominal fee for board and lodging. Nineteen students, representing women of both the industrial and well-educated classes, had completed the two-weeks course, and three a one-week course. It is reported that farmers prefer the well-educated women, although all the women placed seem to have given satisfaction.

**Nature-study in Rhode Island**, W. G. VINAL (*Nature-Study Rev.*, 12 (1916), No. 6, pp. 253-262).—In this lecture, given in the extension course of the Rhode Island Normal School, three large phases are distinguished in nature study, namely, the plant-animal phase or community nature study, coming in the first six grades, the physics-chemistry phase, and the gardening phase—school gardening in the fifth and sixth grades and home gardening or home science in the seventh grade, broadening into civic science in the eighth grade. The author states that nature study is usually limited to the plants and animals and elementary science to physics and chemistry. They are both scientific and they are both nature study, the only difference being that in nature study emphasis is placed on the appreciative side whereas in elementary science the subject is placed first. He discusses the value of nature study, organization of material, method of teaching and aids, such as museums, field trips, illustrative material, and exhibits. It is recommended that the material selected include the daily problems of science which are met by the pupils, other things and that every one should know, and the individual needs of the neighborhood, and that the instruction be given by means of illustrations followed by project work.

**September nature-study**, ANNA B. COMSTOCK (*Nature-Study Rev.*, 12 (1916), No. 6, pp. 280-289, figs. 4).—The author outlines nature study topics for grades 2, 3, 4, and 5 to be used in connection with her Handbook of Nature Study.

**Home school gardens** (*Agr. Gaz. Canada*, 3 (1916), No. 7, pp. 638-647, figs. 2).—This is a collection of articles on the method of conducting home school gardens, their inspection, the number of gardens, etc., in the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, Quebec, Ontario, Manitoba, and Saskatchewan.

[**School home gardening**] (*U. S. Dept. Int., Bur. Ed., School Home-Garden Circs.* 1915, Nos. 1, pp. 4; 2, pp. 4; 3, pp. 3; 4, pp. 2; 1916, Nos. 5, pp. 5, figs. 2; 6, pp. 4; 7, pp. 6; 8, pp. 3; 9, pp. 3; 10, pp. 4; 11, pp. 14).—These circulars, intended to help teachers and garden supervisors, deal respectively with (1) Instructions for School-supervised Home Gardens, (2) A Course in Vegetable Gardening for Teachers, (3) The Winter Vegetable Garden [in the South], (4) Organic Matter for the Home Gardens, (5) Hotbeds and Cold Frames for Home Gardens, (6) Raising Vegetable Plants from Seed, (7) How to Make the Garden Soil More Productive, (8) Planting the Garden, (9) Part Played by the Leaf in the Production of a Crop, (10) A Suggestive Schedule for Home-garden Work in the South, and (11) List of Publications for the Use of School Home-garden Teachers.

**A brochure on school gardens**, H. J. DAVIES (*Dept. Land Rec. and Agr., United Prov. Agra and Oudh, Bul.* 34 (1915), pp. 17).—Instructions for school flower gardens in the hills and plains of the United Provinces of Agra and Oudh, India, are given.

Equipment for teaching domestic science, HELEN KINNE (*Boston: Whitcomb and Barrows, 1916, pp. [6]+104, pls. 16, figs. 28*).—In this revision (E. S. R., 25, p. 393) chapters are added on Portable Equipment for Lectures, and New Developments in Household Arts Equipment, including the practice house, the school apartment, the unit kitchen, and the school lunch room as a cooking laboratory.

Food and nutrition laboratory manual, ISABEL BEVIER (*Boston: Whitcomb and Barrows, 1915, pp. 80*).—To this manual, previously noted (E. S. R., 20, p. 775), considerable new material has been added, and the classification and methods of experimentation have been revised on the basis of present knowledge.

Clothing and health, HELEN KINNE and ANNA M. COOLEY (*New York: The Macmillan Co., 1916, pp. VII+302, pl. 1, figs. 150*).—This is an elementary textbook, in story form, dealing with elementary processes in sewing, making simple garments, care and repair of clothing, choosing and wearing clothes, and leading textile materials.

### MISCELLANEOUS.

Program of work of the United States Department of Agriculture for the fiscal year 1917, E. H. BRADLEY (*Washington: Govt., 1916, pp. 502*).—The proposed activities of this Department are set forth in project form.

Report of Porto Rico Station, 1915 (*Porto Rico Sta. Rpt. 1915, pp. 45, pls. 3*).—This contains the organization list, a summary by the agronomist in charge as to the general conditions and lines of work conducted at the station during the year, reports of the chemist and assistant chemist, horticulturist, assistant horticulturist, plant pathologist, and entomologist abstracted elsewhere in this issue, and a special article entitled A Porto Rican Disease of Bananas noted on page 352.

Twenty-eighth Annual Report of Texas Station, 1915 (*Texas Sta. Rpt. 1915, pp. 43, figs. 2*).—This contains the organization list, a financial statement for the federal funds for the fiscal year ended June 30, 1915, and for various state funds for the fiscal year ended August 31, 1915, and a report of the director on the work of the station and the various substations.

Monthly Bulletin of the Ohio Agricultural Experiment Station (*Mo. Bul. Ohio Sta., 1 (1916), Nos. 10, pp. 289-320; 11, pp. 321-352, figs. 12*).—These numbers contain, in addition to several articles abstracted elsewhere in this issue, the following:

No. 10.—Influence of Sulphur on Crop Production, by J. W. Ames and G. E. Boltz, an abstract of Bulletin 292 (E. S. R., 35, p. 220); Mulching the Apple Orchard, by F. H. Ballou, an extract from Bulletin 301 (E. S. R., 36, p. 40); and The Ohio Soil Survey, by W. C. Boardman.

No. 11.—Roughages for Fattening Lambs, by J. W. Hammond, an abstract of Bulletin 245 (E. S. R., 28, p. 671); Producing Mulch Material in Apple Orchards, by F. H. Ballou, an extract from Bulletin 301 (E. S. R., 36, p. 40); Observations on the Wheat Harvest of 1916, by C. G. Williams; Fall Steaming of Tobacco Plant Beds to Prevent Root Rot, by A. D. Selby, T. Houser, and J. G. Humbert; and Problems of the Southeastern Ohio Farmer, by C. W. Montgomery.

Monthly bulletin of the Western Washington Substation (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 8, pp. 16, figs. 5*).—This number contains brief articles on the following subjects: Production Costs in Dairying, by H. L. Blanchard; Improve Soils by Drainage, by E. B. Stookey; The Logic of the Winter Feeding Schedule, by Mr. and Mrs. G. R. Shoup (see p. 373); Spur Blight of Red Raspberries, by A. Frank; Trap the Moles Now; and Winter School for Farmers.

## NOTES.

---

**Alabama College and Station.**—Dr. J. T. Anderson, professor of chemistry and chemist for soil and crop investigations, died February 25, at the age of 67 years. Dr. Anderson had been connected with the institution for twenty-nine years. Much of his station work had been in connection with the fertilizer inspection, but he had also studied for a long time the nutrition of the cotton plant and had in progress an Adams Act project on the determination of the fertilizer requirements of the soil by analysis of the cotton plants grown on it. He had also been studying the factors affecting the application and insecticidal efficiency of arsenicals. He was an early worker in the Association of Official Agricultural Chemists and was an abstractor for several years from that association for *Experiment Station Record*.

Miss Madge J. Reese, state home demonstration agent, and Miss Mary Paxton, assistant state home demonstration agent, have resigned.

**California University and Station.**—Four-year professional courses in forestry and forest engineering have recently been established. A twelve weeks' short course is also being given, beginning January 15, to help practical woodsmen. The work includes theoretical training in surveying, log-scaling, timber estimating, logging, fire protection, silviculture, forest administration, trail and telephone construction, English composition, grazing, and the work of the United States Forest Service.

Arnold V. Stubenrauch, professor of pomology and pomologist, died February 12. Professor Stubenrauch was born in New Orleans, April 27, 1871, and was graduated from the University of California in 1899. In 1901 he received the M. S. degree from Cornell University and for the next year was instructor in horticulture in the University of Illinois. In 1902 he returned to California, serving until 1905 as assistant professor of horticulture. For the next ten years he was connected with the Office of Horticultural and Pomological Investigations of the U. S. Department of Agriculture, for several years with the studies of fruit transportation and storage, and subsequently in charge of the Office until his return to California in 1914. He was a member of numerous horticultural and general scientific societies and the author of a long list of publications of this Department, the California Station, etc.

Professor Stubenrauch was most widely known for his studies of the handling, transportation, and storage of fruits, which led to important changes in methods, especially in California and Florida. He determined the fundamental factors underlying the successful storage of California grapes and discovered the availability of redwood sawdust as a packing material.

**Georgia Station.**—R. W. Allen has been appointed assistant chemist, beginning February 15.

**Kentucky Station.**—L. B. Mann has been appointed assistant in the department of animal husbandry.

**American Society of Agricultural Engineers.**—The tenth annual meeting of this society was held at Chicago December 27-29, 1916.

One of the topics of special interest was the farm tractor. An inquiry as to the Status of Tractors in Nebraska was reported by L. F. Seaton. Question blanks were sent to about 550 owners in all parts of the State, and reports re-

ceived from 215 owners. Unfavorable reports were followed by personal interviews, and it was usually found that the owner was either not making a success of any farm work or, while a good farmer, he was not a mechanic and depended upon inexperienced men to handle the tractor.

Of the total number of owners reporting for the period 1912-1916, 68.6 per cent considered the tractor a good investment, and of the owners reporting for 1915-16, 76.5 per cent so considered it. All things considered, the tractor was thought to be more satisfactory than the horse by 54.4 per cent of the total number reporting, and by 61.1 per cent of those reporting for 1915-16. As to the cost of operation and maintenance, 65.8 per cent reported in favor of the tractor. From the reports made by the total number reporting, it was thought that the tractor would not be a good investment on farms under 270 acres, but the 1915-16 reports indicated 230 acres to be sufficiently large.

The machines were used an average of 66 days a year. The average length of day was 11.8 hours, with 1.25 hours additional required for oiling and general care. The average size of tractors was from 10.31 to 22.1 horsepower, and the average cost of tractors \$564.23. The average cost of repairs was about \$42.50 for the whole year.

The average width of gang used for plowing was 4.46 ft. or four plows, while that used for breaking was 5.2 ft. or about five plows. The rate of speed traveled per hour was 2.48 miles for plowing and 2.24 miles for breaking. The average amount of fuel used per day for plowing was 26.25 gal., at a cost of \$3.50, and for breaking 40 gal. at a cost of \$6.96. The amount of lubricating oil used per day for plowing was 1.77 gal. at a cost of 87.3 cts.; and for breaking 2.52 gal. at a cost of \$1.25.

F. N. G. Kranich discussed *The Tractor's Relation to the Farm and its Machinery*. It was pointed out that the relation of the tractor to the plow is well established and that the plows now used are of special design, horse-drawn gang plows being used in very few cases. It was considered doubtful, however, whether or not the tractor will bring about similar changes in other farm draft and belt power machines. Nearly all the seeding and harvesting machinery in present use is built in units too small to be used economically with the tractor, indicating the necessity of designing this type of machinery so that it may be drawn either by horses or by a tractor. The relation of the tractor to belt power machines does not necessitate a change in machine design, but does necessitate a careful choice on the part of the purchaser as to size so that the tractor will have ample power to drive the machines at their full capacity. The necessity was also pointed out of selecting a tractor and the machinery to go with it in sizes that will prove a paying investment on the farm in question, and of making sure that this machinery will be used a sufficient amount of time during the year to make the proposition a paying one.

E. R. Greer, in a paper on *Developments in Tractor Design*, stated that the developments during the past season have been mostly in the perfection of details. There has been no radical change in the general design of tractors and no type on the market has been eliminated because of its unfitness. An improvement considered very important by the author is the general adoption of a device for clearing the air of dust before it enters the engine cylinder. It was stated further that all types of tractor motor may be equipped with devices so that kerosene may be burnt successfully, but as a rule the power capacity will be about 10 per cent less in burning kerosene than in burning gasoline.

In a paper on *The Standardization of Gas Tractor Ratings*, R. W. Olney advocated the universal rating of tractors in terms of belt and drawbar horsepower and drawbar pull, as previously explained (E. S. R., 35, p. 890).

O. E. Bransky gave an illustrated talk on Fuels for Internal Combustion Engines, discussing the physical and chemical properties of gasoline and kerosene, including a description of the usual methods followed in producing gasoline and kerosene from crude oil and the so-called Burton process. An evaporation test by means of which the percentages of fuel which are evaporated at different temperatures are determined accurately was advocated in place of the hydrometer test.

In a paper on Magneto Characteristics, it was shown by J. G. Zimmerman from results of tests of two small gas engines that the heat required in both a high tension and make-and-break ignition spark is approximately 0.0025 calorie. The heat value is considered to be the essential factor in the ignition spark, but this heat value must be delivered within a very short period of time. The paper dealt further with sparks, voltage, timing, and the theory of electromagnetic spark generation, the author's purpose being to show how different types of magnetos are designed to produce the kind of spark which is desirable for gas engine ignition.

H. B. Murdock reported on the Drainage of Irrigated Lands, especially as practiced at the Montana Experiment Station. The relief and intercepting systems of drainage were discussed, and special cases of drainage of seeped lands in Montana described in which the use of the systems noted was illustrated. It was brought out especially that the drainage of seeped irrigated lands requires more than a simple survey for the preliminary work. "When drainage of a tract of land is successfully accomplished the work of reclaiming the land is not yet completed, as the soil of the old swamp needs to be put into condition for crops." "The question as to whether it will pay to drain a certain piece of land needs careful consideration as the expense of reclaiming it may be greater than the value of the land; however, it can generally be stated that it pays to drain seeped areas in irrigated lands unless the conditions are very unfavorable for their successful reclamation."

In a discussion of the above paper by O. W. Israelson, results of work reported by the Irrigation Investigations of the U. S. Department of Agriculture were reviewed.

G. W. Iverson presented a paper on Stresses in a Shawver Barn Truss, explaining methods of graphical and analytical computation of stresses. It was shown that this plank truss type of barn frame as usually built should be strong enough to withstand a wind blowing at the rate of 90 miles per hour.

Barn Planning was discussed by W. A. Ashby, who took up the independent stable, shed, loft, basement, and covered barnyard types of live stock barns. The requirements of each type were summarized and translated into figures giving data regarding the average unit space and space for doors, windows, vent flues, and floors, height of ceiling, and width and length of stall for sheep, loose cattle, horses, and milch cows. On the basis of this material a concrete example of barn planning was worked out step by step, illustrating the points discussed and the application of the data.

M. L. King presented a paper on Hollow Clay Blocks for Farm Buildings. The development of permanent and fire-proof farm structures as well as features of their design were dealt with, and a standard test for fire-proof farm residence construction was proposed, based on the author's experience.

A paper on Masonry Roofs, based on experimental work at the Iowa Experiment Station, was presented by W. G. Kaiser. The general features of design of a reinforced concrete and hollow tile arch barn roof following the equation of an inverted catenary were discussed.

Other papers included that on College Instruction in Concrete Construction, by A. J. R. Curtis, prepared from the standpoint of the teacher; Short-course Instruction in Gas Engines and Tractors, by L. F. Seaton, in which the practice in this connection of about twelve agricultural and mechanical colleges in the Central West was outlined; Standardization of Sprocket Wheel Design, by W. F. MacGregor, discussing a paper on the same subject presented by F. N. G. Kranich at the 1915 meeting; Cotton Machinery, by E. C. Gee, based on experience at the Texas College; Use of the Tractor on Eastern Farms, by H. R. Burr, based on work conducted at the Williamson School of Delaware County, Pa.; The Arrangement and Planning of the Farmstead, by L. W. Chase and M. C. Betts, who covered in a semi-popular way the arrangement of farm buildings, lots, etc., with reference to practically every ordinary type of farm activity; What Should the Farmhouse Cost, by W. A. Etherton, who presented data collected showing the relation of house rent to the weekly income of 7,570 families in 29 cities and the relation of the incomes of 1,363 farms in nine States to the cost of the tenant houses thereon; Electric Equipment for the Farm by W. K. Frudenberg; and Agricultural Engineering Bibliography, by H. E. Horton, proposing to add to the generally accepted classification of agricultural engineering three more divisions, namely cultural, statistical, and economic.

E. M. Merwine presented the report of the farm power machinery committee. This consisted of a report of tests on the power requirements of two corn grinders, three alfalfa grinders, two silage cutters, and a corn husker and shredder.

The committee on farm power, L. F. Seaton chairman, reported tests on the compaction of soils due to the use of tractors, made by the agricultural engineering and agronomy departments of the University of Nebraska. The tests were conducted on stubble and freshly plowed land of fine sandy loam soil, which at the time was in very dry and compact condition. Four types of tractor were used, namely, the light-weight four wheel, the drum drive, the caterpillar, and the heavy-weight four-wheel types. Samples of soil were taken to a depth of 6 in. and sometimes to a depth of 12 in. to determine the weight of the soil in a given volume of space in places where the tractor had passed over. The results showed that very little packing of the soil occurred in stubble ground, and in several cases the ground was looser after the tractor had passed over it than before. This is tentatively attributed to the grouters and the slipping action of the wheels. There was considerably more packing when the moisture content of the soil was higher.

W. F. MacGregor reported the progress of the activities of the committee on tractor ratings.

I. W. Dickerson presented the tentative recommendations of the standards committee on the standardization of the ratings and specifications of low voltage farm electric lighting plants. These consisted essentially of suggestions as to the information which manufacturers of farm electric lighting plants should give in their ratings and specifications.

The report of the committee on sanitation included among other matters a review of about 95 reports on the purification and disposal of rural and farm sewage and on farm and rural water supplies, obtained during the past year from various sources.

Other committees reporting were those on farm structures, tractor demonstrations, tractor ratings, irrigation, and drainage.

E. B. McCormick of the Office of Public Roads and Rural Engineering of this Department, was elected president for the ensuing year. C. K. Shedd of the Iowa College continues as secretary-treasurer.

## CONTENTS OF VOL. 36, NO. 5.

Editorial notes:	Page.
The agricultural appropriation act, 1917-18 .....	401
Recent work in agricultural science .....	411
Notes .....	499

## SUBJECT LIST OF ABSTRACTS.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

Chemical calculations, Ashley.....	411
Chemical constitution and physiological action, Spiegel.....	411
The specificity of proteins and carbohydrates, Reichert.....	411
Relation of carotinoids of cow, horse, sheep, goat, pig, and hen, Palmer.....	411
Reaction of amino acids and carbohydrates as cause of humin formation, Roxas.....	412
Tyrosinase and deamination, Schweizer.....	412
The chymase of <i>Solanum elaeagnifolium</i> .—A preliminary note, Bodansky.....	412
The preparation and properties of lead-chlor arsenate, McDonnell and Smith.....	412
Methods for chemical and microscopical diagnosis, Steensma.....	412
A new type of extractor, McNair.....	413
The relative efficiency of laboratory reflux condensers, Dover and Marden.....	413
Extending the usefulness of a shaking machine, Chapin and Schaffer.....	413
Aeration method for ammonia, Davisson, Allen, and Stubblefield.....	413
Does vanadium interfere with determination of phosphorus? Gortner and Shaw.....	413
Examination of a radio-active fertilizer, Jorissen.....	414
The solubility of leucite in sulphurous acid, Schroeder.....	414
Report of the seventh convention of Dutch food chemists.....	414
Improved apparatus for acidity determinations of corn, Besley and Baston.....	414
An improved method for the detection of arachidic acid, Kerr.....	414

	Page.
The determination of citric acid in milk, Kunz.....	415
The determination of gum and pectin in filter residues, Van der Linden.....	415
The sirup precipitate in white sugar manufacture, Coates and Slater.....	415
The composition of sound and frozen lemons, Bailey and Wilson.....	416
Production of sweet-orange oil and a new machine for peeling citrus fruits....	416
The effect of curing on the aromatic constituents of vanilla beans, Rabak.....	416
Notes on the production of oil of citronella, de Jong.....	417
The use of bark for paper specialties, Kress.....	417

## METEOROLOGY.

The effect of climate and soil upon agriculture, Spafford.....	417
The probable growing season, Reed.....	418
Weather insurance, Reed.....	418
Condensed meteorological reports, Georgeson.....	418
Meteorological observations at Massachusetts Station, Ostrander and Sims....	418
Monthly Weather Review.....	419
[Observations on aerology].....	419
Notes on least squares, the theory of statistics and correlation, Marvin.....	419

## SOILS—FERTILIZERS.

Soil survey of the Ukiah area, California, Watson and Pendleton.....	420
Soil survey of Washington County, Georgia, Winston, et al.....	420
Soil survey of Wilkes County, Georgia, Long.....	420
Soil survey of Coahoma County, Mississippi, Hutton et al.....	420
Soil survey of Dickey County, North Dakota, Bushnell et al.....	421
Loess soils of Nebraska.—V, Water-soluble constituents, Upson et al.....	421
Factors affecting evaporation of moisture from soil, Harris and Robinson.....	421
Keep our hillsides from washing, Whitson and Dunnewald.....	422
Protozoa as affecting bacterial activities in the soil, Waksman.....	422
Nitrification in semiarid soils, I, Kelley.....	422
The nitric nitrogen content of the country rock, Stewart and Peterson.....	423
Distribution of phosphorus in a vertical section of bluegrass soil, Peter.....	424
Nature of the sulphur in moorland soils injurious to plant growth, Thörner....	424
Field tests of fertilizer action on soil aldehydes, Skinner and Noll.....	424
Soil fertility.....	425
The use of fertilizers to increase crop production, Stookey.....	425
Improvement of hill and peaty pastures.....	425
The necessity for guano in national agriculture.....	425
Factors affecting absorption and distribution of ammonia applied to soils, Cook..	425
Investigation and valuation of crude calcium cyanamid, Liechi and Truninger....	426
Effect of water on decomposition of crude calcium cyanamid, Hager and Kern..	426
Calcium cyanamid, Malpeaux.....	427
Phosphate fertilizers for Hawaiian soils and their availability, McGeorge.....	427
Phosphate fertilizers, Sutherland.....	428
The citric acid solubility of the phosphate in Thomas slag, Kroll.....	428
The conservation of phosphate rock in the United States, Phalen.....	428
The salt and alkali industry, Martin, Smith, and Milsom.....	428
"Loog as;" or the ash of the alkali bush, Stead.....	429
Chemical analysis of ash.....	429
Relation of the use of lime to the improvement of the soil, Fippin.....	429
Analyses of commercial fertilizers and home mixtures, Cathcart et al.....	429

## AGRICULTURAL BOTANY.

A textbook of botany for colleges, Ganong.....	429
Some recent researches in plant physiology, Atkins.....	429
The principles of plant teratology, Worsdell.....	430
Morphology of the flowers of <i>Zea mays</i> , Weatherwax.....	430
Xerophotic movements in leaves, Gates.....	430
The daily movements of leguminous leaflets, Gates.....	430
The warm-water treatment of seeds difficult to germinate, Honing.....	430
The physiology and technique of forcing growth in woody plants, la Marca....	431
Injury to vegetation resulting from climatic conditions, Stone.....	431
Formation of parenchyma wood following winter injury to the cambium, Mix...	431

	Page.
Effect of sodium salts in water cultures on absorption of plant food, Breazeale...	431
Assimilation of iron by rice from certain nutrient solutions, Gile and Carrero...	431
The influence of manganese on plants, Masoni.....	432
The nutrition of green plants by means of organic substances, Ravenna.....	432
Disappearance of cumarin, vanillin, pyridin, and quinolin in soil, Robbins....	432
Studies in permeability.—III, Absorption of acids by plant tissue, Hind.....	433
Production of root hairs in water, Bardell.....	433
A method for maintaining a constant volume of nutrient solutions, Clark.....	433
Proposed classification of the genus <i>Rollinia</i> , with new species, Safford.....	433
<i>Desmopsis</i> , a new genus of <i>Annonaceæ</i> , Safford.....	433
<i>Pleiospermium</i> , a new genus related to <i>Citrus</i> , Swingle.....	433
Origin of new varieties of <i>Nephrolepis</i> by orthogenetic saltation, I, Benedict..	434
The mutual influence of genotypical factors, Tammes.....	434
Dry grassland of a high mountain park in northern Colorado, Ramaley.....	434
Fungus flora of Texas soils, Werkentlin.....	434
Relative importance of fungi and bacteria in soil, Conn.....	434

## FIELD CROPS.

Report of [field crops] work at Fairbanks Station, Neal.....	435
Report of [field crops] work at Kodiak Station, Snodgrass.....	435
Report of [field crops] work at Rampart Station, Gasser.....	436
[Field crop] notes at Sitka Station, Anderson.....	437
Results of experiments, 1915, Richardson.....	437
Pasture crops in the prairie provinces, Harrison and Bracken.....	437
Germination experiments with grasses and legumes, Burgerstein.....	437
Crucifers and grasses with reference to soil nitrogen, Pfeiffer et al.....	438
Grasses with creeping roots.—Advantages and disadvantages, Breakwell.....	438
[The production of young grass with sulphate of ammonia], Neubauer et al.....	438
[Chlorin requirement of the buckwheat plant], Pfeiffer and Simmermacher...	439
Corn growing under droughty conditions, Hartley and Zook.....	439
Some factors influencing yield in maize, Wenholtz.....	439
Hulled oats, Overgaard.....	439
Potato experimental fields, 1915-16, Ramsay.....	440
Sweet potato curing in Texas, Cole.....	440
Relationship between the average wheat yield and winter rainfall, Richardson.	440
Experiments with the manuring of wheat, Coleman.....	440
Researches on wheat selection, I, Richardson and Green.....	440
The cross-fertilization of wheats, Spafford.....	441
Wheat breeding in New South Wales, Pridham.....	441
Notes on some recently imported wheats, Guthrie and Norris.....	441
Seed wheat.—Varieties for distribution among farmers, Richardson.....	441
Cost of production of field crops, Wilson and Whelan.....	441
Improved apparatus for determining the test weight of grain, Boerner.....	441
Rules and regulations under the United States Grain Standards Act, Houston.	442
Clover and grass seed inspected in 1914, Smith.....	442
Determination of the seeds of <i>Cuscuta trifolii</i> and <i>C suaveolens</i> , Bernatsky....	442
A new weed, Quinn and Andrew.....	442
Some points in fan weed control.....	442

## HORTICULTURE.

[Horticultural investigations in Alaska], Georgeson, Anderson, et al.....	442
Some garden plants in the Portici Royal Agricultural High School, de Rosa...	443
Two winter salads, endive and Witloof, Bussard.....	443
Modern fruit marketing, Brown.....	443
The Christ-Junge taxation method; general rules for horticultural plants.....	443
Cost of producing apples in Wenatchee Valley, Wash., Miller and Thomson.....	443
The general cost of establishing a meadow orchard of cider apples, Truelle.....	444
Methods and problems in pear and apple breeding, Ballard.....	444
Pear breeding, Ballard.....	444
Growing cherries east of the Rocky Mountains, Gould.....	444
Self-sterility in dewberries and blackberries, Detjen.....	444
The sycamore fig in Egypt, Brown and Walsingham.....	445
The best papaws.....	445
<i>Cocos nucifera</i> , Hunger.....	445
The cultivation of limes, Harrison et al.....	445

	Page.
The vanilla plantations of Tahiti and Moorea, Meinecke.....	445
Germination of yerba, Garin.....	445
Yerba maté ( <i>Ilex paraguayensis</i> ), Bertonl.....	455
The American nut industry, Gossard.....	445
Effects of large applications of fertilizers on carnations, Beal and Muncie.....	445
The history and botanical relationships of the modern rose, Wilson.....	446
Some suggestions for improvement of the home grounds, Sill.....	446

## FORESTRY.

Handbook for rangers and woodsmen, Taylor.....	446
The germination and early growth of forest trees, Boerker.....	447
Variations in the anatomical structure of wood, Prichard and Bailey.....	447
Relationship of the Douglas fir to lime in soil, Somerville.....	447
The girth increment of <i>Hevea brasiliensis</i> , Petch.....	447
Sugar pine, Larsen and Woodbury.....	447
The forests of Worcester County, Cook.....	447
Improving the woodlot, Berry.....	447
Scientific national forestry for New Zealand, Hutchins.....	448
Annual statistics relating to forest administration in British India, 1914-15.....	448
Snow, injury to trees, Rigg.....	448
Forest fires in the United States in 1915, Peters.....	448
Forest insurance against fires in Finland, Nylander.....	448
Better apparatus for forest fire fighting, Johnson.....	448

## DISEASES OF PLANTS.

Plant diseases, Anderson.....	448
Mycology, Shaw.....	448
Nonparasitic stem lesions on seedlings, Hartley.....	449
Life history and poisonous properties of <i>Claviceps paspali</i> , Brown.....	449
<i>Neocosmospora vasinfecta</i> on potato and adzuki bean, Wolf.....	450
Pleosphærulina on alfalfa, Jones.....	450
Dissemination of bur clover leaf spot, Wolf.....	450
Experiments to control late blight of celery.....	450
The Rio Grande lettuce disease, Carpenter.....	450
A new smut on <i>Sorghum halepense</i> , Evans.....	450
Control of the sugar-beet nematode, Shaw.....	450
Rhizoctonia and <i>Sclerotium rolfsii</i> on sweet potatoes, Harter.....	451
A specific mosaic disease in <i>Nicotiana viscosum</i> , Allard.....	451
Tomato blight, Jones.....	451
<i>Phytophthora infestans</i> on tomatoes, Kern and Orton.....	451
<i>Phomopsis mali</i> on young apple and pear trees in California, Smith.....	451
Observations on sour sap disease of apricots, Phillips.....	451
A new leaf spot disease of cherries, Rudolph.....	452
The action of copper sulphate on downy mildew, Semichon.....	452
The action of copper salts against grape downy mildew, Semichon.....	452
Some new strawberry fungi, Stevens and Peterson.....	452
The diseases of bananas, van der Laat.....	452
<i>Sclerotium rolfsii</i> on citrus, Wolf.....	452
Cottony rot of lemons in California, Smith.....	452
A Gloeosporium disease of the almond probably new to America, Czarnecki.....	453
The hard rot disease of gladiolus, Massey.....	453
Red leaf spot of <i>Hippeastrum</i> , Dougherty.....	453
Notes on oleander bacteriosis, Smith.....	453
Spraying experiments to prevent rose leaf blotch.....	453
Forest botany, Hole.....	453
Fungus diseases of trees, Maxwell.....	453
A fertile witches' broom on larch, Jaccard.....	453
<i>Peridermium harknessii</i> and <i>Cronartium quercuum</i> , Meinecke.....	454
<i>Pinus resinosa</i> , a new host for <i>Peridermium acicolum</i> , Pierce.....	454
White pine blister rust ( <i>Peridermium strobil</i> ).....	454
[Disease in pine and chestnut], Rane.....	454
Spread of the chestnut blight in Pennsylvania, Metcalf.....	454
Influence of Bordeaux mixture on transpiration from leaves and plants, Martin.....	454
Sulphur fungicides, Gray.....	455

## ECONOMIC ZOOLOGY—ENTOMOLOGY.

	Page.
Laws relating to fur-bearing animals, 1916, Lantz.....	455
Canaries: Their care and management, Wetmore.....	455
Shading effect of wire insect cages, Kimball.....	455
Wetting power of nicotin-sulphate and fish-oil-soap sprays, Smith.....	455
Cyanid gas for the destruction of insects, Creel and Faget.....	456
Some effects of freezing arsenate of lead pastes, Dutcher.....	456
Forty-sixth annual report of the Entomological Society of Ontario, 1915.....	456
Insect pests [in Sitka district], Anderson.....	457
Report of the entomologist for the year 1915-16, Ritchie.....	457
Some phases of the locust problem, Loundsbury.....	457
The cockroach: Its destruction and dispersal, Holt.....	457
The green apple bug ( <i>Lygus invitus</i> ) in Nova Scotia, Britain.....	457
Studies of life histories of froghoppers of Maine, Osborn.....	458
<i>Macrosiphum granarium</i> , the English grain aphid, Phillips.....	458
Effects of certain leaf-feeding Coccidæ and Aphididæ on pines, Brown.....	459
Life history of the velvet bean caterpillar ( <i>Anticarsia gemmatilis</i> ), Watson.....	459
Oviposition of infertile eggs and parthenogenesis in the silkworm, Lécaillon.....	459
The cochylis, Faes and Porchet.....	460
Reducing malaria by reducing the number of Anopheles within buildings, Zetek.....	460
Ronald Ross and the prevention of malarial fever, Gorgas and Garrison.....	460
Syrphidæ of Maine, Metcalf.....	460
The attraction of Diptera to ammonia, Richardson.....	460
A contribution to the knowledge of dipterous larvæ and pupæ, de Meijere.....	460
The transmission of disease by flies, Sweet.....	460
Sciara maggots injurious to potted plants, Hungerford.....	460
The occurrence of two annual generations of the elm-leaf beetle, Lécaillon.....	461
The dock false worm: An apple pest, Newcomer.....	461
Observations upon some of the predacious and parasitic Hymenoptera, Fyles.....	461
<i>Syntomaspis druparum</i> , the apple-seed chalcid, Cushman.....	461
An efficacious endoparasite of <i>Chrysomphalus dictyospermi</i> , Berlese and Paoli..	462

## FOODS—HUMAN NUTRITION.

Fats and their economical use in the home, Holmes and Lang.....	462
Methods of preserving and manufacturing meat products, Cassamagnaghi.....	463
The food value and uses of poultry, Atwater.....	463
The sanitation of the shellfish industry, Cumming.....	463
A preliminary chemical study of the rices of Bihar and Orissa, Sen.....	463
North Dakota wheat for 1916, Ladd.....	464
Science of baking business with special reference to yeast foods, Allen.....	464
Experiments in bread making from different kinds of rye, Jensen and Ludvigsen.....	464
Bread as a food.—Its vitamin content and nutritive value, Voegtlin et al.....	464
Bread as a food.....	466
Evaporated fruit and vegetables, McGill.....	466
Coconut products and other substitutes for butter.....	466
Coconut toddy in Ceylon, Browning and Symons.....	466
Composition of Hungarian wines, Vuk.....	466
Mace, McGill.....	466
Boric acid occurring naturally in some foods, Smith.....	466
[Drug analyses], Ladd and Johnson.....	467
Annual report of the state chemist of Florida, Rose.....	467
Sixteenth annual report of the state food commissioner of Illinois, Matthews..	467
Report on the enforcement of the pure food law, Soule.....	467
Report of deputy state sealer of weights and measures, Russ.....	467
Homemade fireless cookers and their use.....	467
Is vegetarianism based on sound science? Keith.....	467
Action of sodium citrate and its decomposition in the body, Salant and Wise..	467
Elimination of malates after subcutaneous injection of sodium malate, Wise.....	468
The behavior of tartaric acid and the tartrates in the animal organism, Kahn..	468

## ANIMAL PRODUCTION.

Annual review of investigations in general biology, compiled by Delage et al..	468
Animal production, von Ollech.....	468
The pituitary gland.—Its effect on planarian worms, Wulzen.....	468
Use of energy values in the computation of rations for farm animals, Armsby..	469

	Page.
Energy values of red-clover hay and maize meal, Armsby et al. ....	469
Composition and digestibility of several meadow grasses, Honcamp et al. ....	469
[Animal husbandry work in Alaska], Georgeson and Snodgrass. ....	469
A list of breeders of pure-bred live stock in Montana. ....	470
Utilization of feed by range steers of different ages, II, Christensen et al. ....	470
Experiments in hog feeding at the Delta Branch Station, Walker. ....	471
Feeding experiment with a mixed feed, von Czadek. ....	472
Distribution of public service stallions in Wisconsin in 1916, Alexander. ....	472
Concerning poultry feed values, Shoup. ....	473
Dwarf eggs of the domestic fowl, Pearl and Curtis. ....	473
A list of breeders of standard-bred poultry in Montana. ....	473

#### DAIRY FARMING—DAIRYING.

Report of the Sixth International Dairy Congress. ....	473
Judging dairy cows, Humphrey. ....	473
[A new world's champion dairy cow]. ....	473
Reducing the cost of milk production, Blanchard. ....	473
A review of the milk situation in New York, Dillon. ....	474
Common sense in dairy inspection, Kelly. ....	474
The grading of milk in small communities, Williams. ....	474
The new state dairy law, Roadhouse. ....	474
The heat resistance of nonspore-forming bacteria in milk, Gorini. ....	474
Value of pasteurization in milk infected with tubercle bacilli, Traum and Hart. .	474
Rate of multiplication of bacteria in raw and pasteurized milk, Allen. ....	475
Relation of lactic acid bacteria to milk freshness, Voitkevich (Wojtkiewicz). .	475
Using milk of low bacterial content in studying fermentation, Burri and Hohl. .	476
A common statement concerning the number of bacteria in milk, Breed. ....	476
Cheese factory and creamery instruction and inspection. ....	476
Chromogenic micro-organisms of cheese and in "robbiola," Dalla Torre. ....	477
The preparation of homemade rennet, Todd and Cornish. ....	477

#### VETERINARY MEDICINE.

Pathology and differential diagnosis of infectious diseases of animals, Moore. .	477
Special Pathology and Therapeutics of the diseases of domestic animals, Hutyrá and Marek, edited by Mohler and Eichhorn. ....	477
Special pathology and therapy of domestic animals, Fröhner and Zwick. ....	478
The origin and development of the lymphatic system, Sabin. ....	478
Relationship between serum reactions, Wehrbein. ....	478
Relation of specific precipitation to other immunity reactions, Bulger. ....	478
Hypodermal anaphylaxis, Torrance. ....	478
The effect of toluene on the production of antibodies, Hektoen. ....	479
Comparative action of antiseptics on pus and on pure cultures, Lumière. ....	479
Significance of certain natural flagellates of insects, Fantham and Porter. ....	479
Observations on the blood in East Coast fever of cattle, Strickland. ....	479
The mallein ophthalmic test as a diagnostic aid in glanders, Bongert. ....	480
Tetanus bacilli on surface of parts of projectiles left in wounds, Lumière. ....	489
Value of the avian tuberculin test of Van Es and Schalk, Schornagel. ....	480
The intracutaneous tuberculin test of Van Es and Schalk, Jakob and Gazenbeek. .	480
A study of the milk in bovine infectious abortion, Giltner et al. ....	480
Significance and duration of immunity in bovine contagious abortion, Ascoli. .	481
The seasonal prevalence of <i>Hypoderma bovis</i> in 1915, Hadwen. ....	482
Castration of young pigs, Ashbrook. ....	482
Hog cholera. ....	482
Methods of vaccination, control, and eradication of hog cholera. ....	482
<i>Bacillus abortus</i> in infectious abortion in swine, Good and Smith. ....	483
Equine spirillosis in Morocco, Velu. ....	483
Leukemia of the fowl: Spontaneous and experimental, Schmeisser. ....	483
Flagellated protozoa in infective processes of intestines and liver, Hadley. ....	483

#### RURAL ENGINEERING.

The people's interest in water-power resources, Smith. ....	484
Accuracy of stream-flow data, Grover and Hoyt. ....	484
The measurement of silt-laden streams, Pierce. ....	484
Surface water supply of the Pacific slope basins in California, 1913. ....	484

	Page.
Surface waters of Massachusetts, Pierce and Dean.....	484
Ground water in southeastern Nevada, Carpenter.....	485
The Navajo country, Gregory.....	485
Harney and Silver Creek projects, irrigation and drainage, Whistler and Lewis..	485
Artesian water for irrigation in Little Bitterroot Valley, Mont., Meinzer.....	486
The alkali content of irrigation waters, Stewart and Hirst.....	487
Tests of irrigation pumping plants, Cates.....	487
Experiments with submerged orifices and tubes, Rogers and Smith.....	488
The significance of streptococci in water supplies, Savage and Read.....	489
Results from the activated sludge sewage treatment plant of Milwaukee, Hatton.	489
Public road mileage and revenues in the New England States, 1914.....	489
Report of the State Commissioner of Highways [of New York], Duffey.....	489
Proposed motor-truck loads for highway bridges, Childs.....	489
Tractive resistances to a motor delivery wagon, Kennelly and Schurig.....	490
First national farm tractor directory, compiled by Stone.....	491
Modern systems of independent lighting and heating.....	491

## RURAL ECONOMICS.

The farmer's labor income, Vogt.....	491
Labor income does not determine true profits, Falconer.....	492
Farm profits on 370 potato farms in Monmouth County, New Jersey, App.....	492
Factors affecting methods of farm management in the North Island, Brown..	493
[Agricultural laws of North Dakota].....	493
The Federal Farm Loan Act.....	493
Digest of the Federal Farm Loan Act.....	493
[Agricultural credit in India and Netherland East Indies], Douie and Alting..	493
[Annual reports of the marketing commissioners], Smith et al.....	493
Relation between primary market prices and qualities of cotton, Taylor.....	493
Advertising the apple, Sears.....	494
Saint Paul, the northwestern market for diversified farming.....	494
Minneapolis, "the market of the northwest".....	494
[Raleigh as the location of a Federal farm loan bank], Withers.....	494
[Agriculture in North Carolina].....	494
Report from the seed and plant distribution.....	494
Agricultural statistics, Ireland, 1916, Butler.....	494
[Agricultural statistics in Germany].....	494
Agriculture in India, Mackenna.....	494

## AGRICULTURAL EDUCATION.

Report of agriculture in the high schools of Michigan, French.....	495
The work of the college of agriculture, Copeland.....	495
The Agricultural Instruction Act.....	495
Agricultural education and live stock improvement in Wales.....	495
Instruction in light farm work and milking for women and children.....	496
Farm mechanics.....	496
The kingdom of the plants, Norcross and Lehenbauer.....	496
Twenty lessons in domestic science, Fisher.....	496
A series of lessons in cooking and household management, Hullinger.....	497
An outline on the history of cookery, Barrows et al.....	497
Clothing for women, Baldt.....	497
Shelter and clothing, Kinne and Cooley.....	497
Food and health, Kinne and Cooley.....	497
A course in household arts, I, Duff.....	497

## MISCELLANEOUS.

Report of Alaska Stations, 1915.....	497
Twenty-seventh Annual Report of North Dakota Station, 1916.....	498
Monthly Bulletin of the Western Washington Substation.....	498
The mutual relations of experimental and extension institutions, Emelianov..	498

# LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	Page.	<i>U. S. Department of Agriculture.</i>	Page.
Alaska Stations:		Jour. Agr. Research, vol. 7:	
Rpt. 1915.....	418, 429, 435, 436, 437, 442, 448, 457, 469, 494, 497	No. 9, Nov. 27, 1916.	431, 449, 455, 469
Hawaii Station:		No. 10, Dec. 4, 1916.....	421, 422
Bul. 41, Dec. 2, 1916.....	427	No. 11, Dec. 11, 1916... ..	451, 458, 461
Indiana Station:		No. 12, Dec. 13, 1916.....	431, 454
Circ. 56, Aug., 1916.....	482	Bul. 265, The Dock False Worm: An Apple Pest, E. J. New- comer.....	461
Maine Station:		Bul. 388, Public Road Mileage and Revenues in the New England States, 1914.....	489
Bul. 253, July, 1916.....	460	Bul. 399, The Production of Sweet- Orange Oil and a New Machine for Peeling Citrus Fruits, S. C. Hood and G. A. Russell.....	416
Bul. 254, Sept., 1916.....	458	Bul. 426, Sugar Pine, L. T. Larsen and T. D. Woodbury.....	447
Bul. 255, Oct., 1916.....	473	Bul. 446, The Cost of Producing Apples in Wenatchee Valley, Wash., G. H. Miller and S. M. Thomson.....	443
Maryland Station:		Bul. 457, Relation Between Pri- mary Market Prices and Qualities of Cotton, F. Taylor.....	493
Bul. 196, Apr., 1916.....	443	Bul. 459, Use of Energy Values in the Computation of Rations for Farm Animals, H. P. Armsby... ..	469
Bul. 197, July, 1916.....	442	Bul. 467, The Food Value and Uses of Poultry, Helen W. Atwater ... ..	463
Massachusetts Station:		Bul. 469, Fats and their Economical Use in the Home, A. D. Holmes and H. L. Lang.....	462
Met. Buls. 335-336, Nov.-Dec., 1916.....	418	Bul. 472, Improved Apparatus for Determining the Test Weight of Grain, with a Standard Method of Making the Test, E. G. Boerner.....	441
Mississippi Station:		Farmers' Bul. 770, Canaries: Their Care and Management, A. Wet- more.....	455
Bul. 177, Aug., 1916.....	471	Farmers' Bul. 771, Homemade Fireless Cookers and Their Use..	467
Montana Station:		Farmers' Bul. 772, Control of the Sugar-beet Nematode, H. B. Shaw.....	450
Circ. 12, Sup., July, 1915.....	442	Farmers' Bul. 773, Corn Growing Under Droughty Conditions, C. P. Hartley and L. L. Zook....	439
Spec. Circ. 3, Mar., 1916.....	470		
Spec. Circ. 4, Mar., 1916.....	473		
New Jersey Stations:			
Bul. 294, Apr. 20, 1916.....	492		
Bul. 297, Sept. 16, 1916.....	429		
New Mexico Station:			
Bul. 103, June, 1916.....	470		
New York Cornell Station:			
Bul. 380, Sept., 1916.....	453		
North Carolina Station:			
Tech. Bul. 11, Oct., 1916.....	444		
North Dakota Station:			
Bul. 119, Nov., 1916.....	464		
Spec. Bul., vol. 4, No. 9, Nov.- Dec., 1916.....	467		
Twenty-seventh An. Rpt. 1916 [pt. 1].....	425, 482, 498		
Rhode Island Station:			
Bul. 166, June, 1916.....	483		
Utah Station:			
Bul. 147, Sept., 1916.....	487		
Washington Station:			
West. Wash. Sta. Mo. Bul., vol. 4—			
No. 9, Dec., 1916..	425, 473, 498		
No. 10, Jan., 1917.....	473, 498		
Wisconsin Station:			
Bul. 272, Aug., 1916.....	422		
Bul. 273, Sept., 1916.....	472		
Bul. 274, Oct., 1916.....	473		

<i>U. S. Department of Agriculture—Con.</i>	Page.	<i>U. S. Department of Agriculture—Con.</i>	Page.
Farmers' Bul. 776, Growing Cherries East of the Rocky Mountains, H. P. Gould.....	444	Scientific Contributions—Contd.	
Farmers' Bul. 780, Castration of Young Pigs, F. G. Ashbrook....	482	An Improved Method for the Detection of Arachidic Acid, R. H. Kerr.....	414
Farmers' Bul. 783, Laws Relating to Fur-bearing Animals, 1916, D. E. Lantz.....	455	The Composition of Sound and Frozen Lemons with Special Reference to the Effect of Slow Thawing on Frozen Lemons, H. S. Bailey and C. P. Wilson.....	416
Office of the Secretary:		The Effect of Curing on the Aromatic Constituents of Vanilla Beans, F. Rabak...	416
Circ. 68, Improved Apparatus for Use in Making Acidity Determinations of Corn, H. J. Besley and G. H. Baston.	414	The Use of Bark for Paper Specialties, O. Kress.....	417
Circ. 69, Forest Fires in the United States in 1915, J. G. Peters.....	448	Field Tests of Fertilizer Action on Soil Aldehydes, J. J. Skinner and C. F. Noll...	424
Circ. 70, Rules and Regulations of the Secretary of Agriculture under the United States Grain Standards Act of August 11, 1916, D. F. Houston.....	442	Proposed Classification of the Genus <i>Rollinia</i> , with Descriptions of Several New Species, W. E. Safford.....	433
Bureau of Soils:		<i>Desmopsis</i> , a New Genus of <i>Annonaceæ</i> , W. E. Safford..	433
Field Operations, 1914—		<i>Pleiospermium</i> , a New Genus Related to Citrus, from India, Ceylon, and Java, W. T. Swingle.....	433
Soil Survey of the Ukiah Area, Cal., E. B. Watson and R. L. Pendleton.	420	The Vanilla Plantations of Tahiti and Moorea, E. P. Meinecke.....	445
Soil Survey of Dickey County, N. Dak., T. M. Bushnell et al.....	421	<i>Peridermium harknessii</i> and <i>Cronartium quercuum</i> , E. P. Meinecke.....	454
Field Operations, 1915—		The Work Carried on in the United States against the Gipsy and Brown-tail Moths, A. F. Burgess.....	456
Soil Survey of Washington County, Ga., R. A. Winston et al.....	420	The Action of Sodium Citrate and Its Decomposition in the Body, W. Salant and L. E. Wise.....	467
Soil Survey of Wilkes County, Ga., D. D. Long.	420	Elimination of Malates after Subcutaneous Injection of Sodium Malate, L. E. Wise.	468
Soil Survey of Coahoma County, Miss., F. Z. Hutton et al.....	420	Common Sense in Dairy Inspection, E. Kelly.....	474
Weather Bureau:		Special Pathology and Therapeutics of the Diseases of Domestic Animals, F. Hutyrá and J. Marek, edited by J. R. Mohler and A. Eichhorn.	477
Mo. Weather Rev., vol. 44, Nos. 9-10, Sept.-Oct., 1916..	418, 419, 431, 455	Proposed Motor-truck Loads for Highway Bridges, O. W. Childs.....	489
Mo. Weather Rev., Sup. 3....	419

# EXPERIMENT STATION RECORD.

VOL. 36.

APRIL, 1917.

No. 5.

The annual agricultural appropriation act continues to be a document of wide public interest. It constitutes an epitome of the organization and mechanism of the Federal Department of Agriculture and reveals its many and intimate relations with the daily life of the whole American people. In a sense it is an indicator of current opinion as to the most pressing problems of American agriculture and the ways in which an institution of this sort may be expected to aid in solving them. It furnishes a convenient measure of the Department's progress from year to year, as well as a forecast as to its activities and lines of development in the months to come.

The latest of these acts, covering the fiscal year ending June 30, 1918, was signed by President Wilson March 4, in the closing hours of the Sixty-fourth Congress. It was thus enacted only a little over six months subsequent to the belated measure for the current fiscal year; yet it is much more than a mere routine extension of it. Unlike the former act, it contains comparatively little general legislation and inaugurates no single project of outstanding prominence, but it increases a large number of the allotments for the Department's work and affords scope for its development in a number of important ways.

Many of the enlarged appropriations are to provide for its increased administrative and regulatory activities, and for the growth of such enterprises as the cooperative demonstration work in the Northern and Western States, the market news service, the development of dairying and animal husbandry, additional soil surveys, and the improvement of the National Forests. It materially enlarges the funds for the combating of a number of serious pests and diseases of animals and plants, notably tuberculosis, hog cholera, dourine, the pink bollworm of cotton, citrus canker, and white-pine blister rust. It provides additional funds for fiber-plant and cereal studies, biological studies of food and drug products, studies of the relative utility and economy of agricultural products for food, clothing, and other purposes in the home, and for various other projects.

The act converts the Office of Markets and Rural Organization into the Bureau of Markets, and contains a new item of \$50,000 authorizing the bureau to investigate the handling, manufacture,

and distribution of agricultural food products, with special reference to the manipulation of markets or the control of food supplies. The Secretary of Agriculture is empowered, in the discharge of the duties required by the act relating to the Bureau of Markets, to administer oaths, examine witnesses, and call for the production of books and papers. The establishment of an additional experiment station in Alaska and of a weather bureau station at Greenville, South Carolina, are authorized. Provision is made for a \$75,000 laboratory building on the Department's experimental farm near Arlington, Virginia, as permanent quarters for the testing and research work of the Office of Public Roads and Rural Engineering. The act also contains authority to purchase 150 acres of land at Chico, California, in connection with the plant-introduction work, and about 600 acres for the Morgan Horse Farm near Middlebury, Vermont.

The Plant Quarantine Act of 1912 is amended in two important particulars. The Secretary of Agriculture is now given discretionary power to quarantine any State or Territory when in his opinion such quarantine is necessary to prevent the spread of a dangerous plant disease or insect infestation. The scope of the quarantine itself is broadened by the inclusion of stone or quarry products or any other article deemed capable of disseminating a dangerous plant disease or insect infestation.

The appropriations carried in the new act aggregate \$25,929,113. This is an apparent decrease of \$1,019,739 over the total in the current act, but if comparison is attempted between the two fiscal years, allowance must be made for the sum of \$2,000,000 appropriated in the act for the fiscal year 1917 for purchases of land under the Appalachian Forest Reserve Act but not to be expended until the following fiscal year. If the aggregates are corrected accordingly, the appropriation available for 1918 becomes \$2,980,261 in excess of that for 1917, or slightly over eleven per cent.

The new act also carries another increase, in common with several other appropriation acts for the support of other branches of the government, in the form of an indefinite appropriation of such amount as is necessary for additional compensation during the fiscal year of certain full-time employees of the Department. Those receiving less than \$1,200 per annum are granted a salary increase of ten per cent, and those receiving from \$1,200 to not more than \$1,800, one of five per cent. Persons receiving a part of their salaries from outside sources under cooperative arrangements with the Department are not included in this provision. It is estimated that about 12,000 of the more than 17,000 employees of the Department will be affected, and that approximately \$900,000 will be expended for this purpose.

Taking up the allotments of the various bureaus and offices in turn, that of the Weather Bureau is \$1,783,140. An increase of \$30,380 is granted to provide for the normal growth of the service; \$10,000 for the studies of the efficiency of various methods of frost protection for the benefit of orchardists, truck growers, and others; and \$10,000 for additional equipment for storm warning towers on the Gulf coast.

The appropriations directly allotted to the Bureau of Animal Industry aggregate \$3,555,326, but this is, as usual, supplemented by the permanent appropriation of \$3,000,000 per annum for meat inspection and other funds provided elsewhere in the act. The total corresponding allotment for the current year is \$3,020,746, so that the increase is considerable—in fact, one of the largest provided for any bureau.

The inspection and quarantine work of the bureau against animal diseases receives \$628,280, an increase of \$103,500. Of this amount \$75,000 is expected to be used for the development of methods for eradicating tuberculosis in live stock, testing on a larger scale methods which have proved successful in controlling the disease in small areas. It is also planned to use \$25,000 in the inspection and supervision of the disinfection of infected hides, wool, and other animal by-products, with the view of preventing the introduction of dangerous diseases from the new sources of supply instituted by the European war. The remaining increase is to meet the enlarged demand for tuberculin and blackleg vaccine.

A slight extension of the field hog-cholera campaign is provided for by an increased appropriation of about \$15,000, the total for this purpose being \$210,000. There will also be available \$172,240 for the enforcement of the virus-serum-toxin provisions of the act of 1913 and \$32,060 for research work. The dourine appropriation is increased from \$75,000 to \$99,000, of which \$50,000 is made immediately available. This infection has been found to be prevalent over a wider area than was at first anticipated.

The tick eradication campaign is given \$631,560, of which \$50,000 may again be used for live stock and dairy demonstrations in cooperation with the States Relations Service in areas freed of ticks. It is of interest to note that during the past year 16,281,185 inspections were made of cattle for ticks; that 12,662 cattle dipping vats were in operation under Federal or State supervision; and that 31,358 square miles of territory were released from quarantine because of the eradication of the disease.

The allotment for investigations of animal diseases is \$134,600, of which \$50,000 may be used for contagious abortion. The emergency appropriation for the eradication of foot-and-mouth and similar con-

tagious diseases is reduced from \$1,250,000 to \$1,000,000, plus any unexpended balance remaining from the fiscal year 1916.

The supplemental appropriation for meat inspection is \$501,620, a net increase of \$141,600 over the funds for the current year. This will provide for the supervision of some additional establishments and of new departments being added to existing plants.

The recent noteworthy increase of interest in dairying is reflected in an enlargement of the appropriation for that work by \$117,020, or to a total of \$378,930. It is proposed to extend especially the studies and demonstrations of dairy farming; the promotion of dairy manufacturing through creameries in the South and cheese factories in the South and West; dairy research; the market-milk studies, including dairy sanitation, extension work, and problems in milk-plant management; and to begin a campaign to improve the character of dairy products produced and consumed on the farm.

The allotment for animal husbandry is increased \$81,080, the total for this purpose being \$277,580. More attention is to be given to farm sheep, notably in the Middle West and Eastern States, including studies and demonstrations in cooperation with the States Relations Service and the agricultural colleges. A grant of \$12,280 is also included for the equipment of the United States sheep experiment station in Fremont County, Idaho. Studies of beef production in the corn belt in cooperation with the Office of Farm Management are contemplated, and the extension of the pig club and poultry club work is planned for several additional States.

The special appropriation of \$60,000 for experiments and demonstrations in live stock production in the cane sugar and cotton districts is continued, as is also that of \$40,000 for somewhat similar work in the semiarid and irrigated districts. The first-named project is being carried on largely in cooperation with the State of Louisiana, and the experimental work thus far has been mainly with forage-crop production, cattle feeding, and mule raising. Under the second project buildings and equipment are being provided at Ardmore, South Dakota, and Huntley, Montana.

A large increase is also granted for the Bureau of Plant Industry, its total rising from \$2,537,120 to \$3,143,630. This increase is mainly for the combating of plant diseases, especially citrus canker and white-pine blister rust. For the citrus-canker campaign \$180,000 additional is provided, making \$430,000 for the purpose. The increase is immediately available, while it is made discretionary with the Department as regards the remaining \$250,000 to require contributions of an equal amount from other sources. A similar arrangement is made with regard to the \$300,000 appropriation for white-pine blister rust, half of which is made immediately available and the remainder contingent, in the discretion of the Department,

upon equivalent outside contributions. No part of the appropriation for either disease may be used in payment for trees or other property injured or destroyed.

Small increases are also provided to combat several other diseases, notably root rot and similar tobacco troubles, Stewart's disease of sweet corn, a new bacterial disease of wheat, cranberry rot, and some of the diseases of prunes, cherries, pecans, watermelons, tomatoes, lettuce, celery, beans, and alfalfa and other forage plants. Provision is also made for the organization of a plant-disease survey of the United States, with an allotment of \$10,000. Work under this line has hitherto been conducted incidental to the various special inquiries in progress, and it is hoped that this centralization will assist in the estimation of the economic importance and distribution of plant diseases, the discovery and identification of new fungi, the supplying of material to investigators, and in similar ways.

The allotments for crop acclimatization and fiber-plant investigations have been combined and carry a total appropriation of \$82,510. Of this amount at least \$7,500 is to be used for experiments with cotton seed interbreeding, and \$25,000 is for studies of the feasibility of increasing the production of hard fibers, particularly in the Philippine Islands. The item for testing and breeding fibrous plants, with special reference to paper making, has been increased \$5,920 in order to provide for tests of flax tow as a paper-making material.

The sugar-plant studies have been enlarged to include work with sorghums. There is a net increase of \$9,000 in this allotment which will be used for an economic and technical investigation of the status of the sorghum industry, for extending the experimental work with cane sirup, and for special studies in the control of the sugar-beet nematode and curly-top disease of sugar beets.

Other increases for the bureau include \$22,000 for cereal investigations, \$5,000 for a study of the biochemical basis of disease immunity in plants, \$6,600 for additional work on the agricultural significance of nematodes, \$3,000 for seed testing, \$4,500 for developing methods for decreasing the losses of tobacco resulting from weather conditions, \$5,000 for promological studies with a special allotment for work with pecans, and \$7,500 for the further development of the Arlington Experimental Farm.

The foreign seed and plant introduction work receives a net increase of \$23,000, of which \$8,500 is for developing methods for the protection of new plant introductions; \$4,500 for improving the facilities at the field stations at Miami, Florida, and Chico, California; and \$10,000 for establishing an additional station at Bellingham, Washington. The Congressional seed distribution is continued on the customary basis, with an allotment of \$243,720.

The appropriations for the Forest Service, as usual, are greater than those of any other bureau, aggregating \$5,712,275, with \$100,000 additional for cooperation with the States in fire protection work under the Appalachian Forest Reserve Act. As previously noted, there will also be available for expenditure during the fiscal year 1918 the \$2,000,000 provided for land purchases in the appropriation act of the current year.

The bulk of the appropriation is to be utilized for the administration, protection, and development of the National Forests, which it is of interest to note returned in receipts for the fiscal year 1916 a total of \$2,823,540.71. There are a number of increases in the funds for administrative work, and the allotment for permanent improvements has been increased from \$400,000 to \$450,000. This will be used in particular for additional fencing and similar improvements with a view to increase the stock-carrying capacity of the ranges.

The experimental work of the Service is provided for much as usual, with an increase of \$5,000 to extend the grazing and range studies, and a net increase of \$25,000 for the studies of forest products and the demonstration of the results on a commercial scale.

The Bureau of Chemistry receives \$1,200,591, of which \$623,521 is allotted for the enforcement of the Food and Drugs Act. Authority to establish standards of the strength, quality, or purity of articles of food and certain drugs was refused.

Most of the lines of work of the bureau are continued unchanged. A new item of \$7,000 is inserted providing for a study of methods for the manufacture of table sirup, which work has heretofore been carried on under a special allotment of \$4,000 from the Bureau of Plant Industry. The bureau is instructed to study methods of determining maturity in fruits and vegetables in cooperation with the Bureaus of Plant Industry and Markets.

The Bureau of Soils is granted \$363,735, plus any unexpended balance from the \$175,000 appropriation of the current year for experiments and demonstrations of methods of obtaining potash on a commercial scale. There is an increase of \$30,000 to extend the soil surveys, as previously noted, and one of \$5,000 for additional chemical work and studies of the liming of soils.

There is an increase of \$62,600 for the Bureau of Entomology. Of this amount, \$25,000 will be used for investigational work relating to the cotton boll weevil, and lesser amounts for special studies of the Hessian fly, chestnut weevils, insects affecting pecans and other nuts, for the control in cooperation with the Bureau of Plant Industry of insect carriers of plant diseases, and for enlarging the work on insecticides. The establishment of a field laboratory in the Ozark Mountain region in Arkansas and a field station in one of the New

England States in connection with work on the apple-tree tent caterpillar is also contemplated. The gipsy and brown-tail moth campaign is again allotted \$305,050, but the provision with reference to the manner of establishment and maintenance of quarantines against further spread is made to conform with the provisions of the Plant Quarantine Act. The appropriations for the bureau as a whole aggregate \$931,480.

The Bureau of Biological Survey receives \$592,070, a net increase of \$13,840. This will permit of a more complete enforcement of the Lacey Game Act, and provide for additional protection of some of the seventy Federal bird reserves and five large-game preserves. There is a decrease of \$5,000 in consequence of the completion of the inquiries as to the diseases of wild ducks in Utah. The authority to destroy predatory animals is extended to include those which prey upon wild game.

The total appropriation for the States Relations Service is \$3,107,660. This is an increase of \$137,980, of which \$105,200 is to extend the farmers' cooperative demonstration work in the States outside the cotton belt. This will enable the Department to stimulate the development of the county-agent work, the boys' and girls' club work, and the farm-management demonstrations, and make possible a considerable extension of the work with farm women.

There is also an increase of \$12,000 for the Alaska Experiment Stations, of which \$10,000 is made immediately available for the establishment of an additional station in the Matanuska Valley on the line of the new Government railroad. An amendment authorizing a sub-station for experimental work with fruits and vegetables in some suitable location in Porto Rico was adopted by the Senate, but eliminated in conference.

The allotment for the Office of Home Economics is increased from \$24,220 to \$35,000. The work of this office, which deals with the utilization of agricultural products for food, clothing, and other purposes in the home, has hitherto been quite largely with food questions, but it is now hoped to broaden its scope to meet the constantly increasing demand from teachers and housewives for studies of household management and equipment. Opportunity will also be afforded for additional work with various cereal products, green vegetables, the canning of meats in the home, etc.

The remaining lines of work of the States Relations Service are provided for substantially as at present. An increase of \$10,000 is granted for administrative expenses, in consequence of the increase in the funds under the Extension Act from \$1,080,000 to \$2,080,000. The allotments and authority of the Department with reference to

the State experiment stations are continued unchanged. The cooperative demonstration work in the cotton belt receives \$659,560, and the work with farmers' institutes and agricultural schools \$20,600.

The act appropriates \$701,600 for the Office of Public Roads and Rural Engineering as compared with \$599,200 for the current year. Of this increase \$75,000 is for the erection of the laboratory building already noted, and \$5,000 for an extension of the studies of miscellaneous rural-engineering problems. The remainder will be used to meet the increased demands for studies of road management and road materials in connection with the Federal-aid Road Act. The appropriations under this act for the year will aggregate \$10,000,000, of which \$300,000 may be used by the Department for the administration of the act, and with \$1,000,000 additional for the construction of roads and trails in the National Forests.

The new Bureau of Markets receives \$1,718,575, which nearly doubles the allotment to the Office of Markets and Rural Organization in the act for the current year. A considerable part of this increase, however, is due to transfers to the Bureau of duties hitherto not specifically assigned to it. Among these are the grain standardization studies transferred from the Bureau of Plant Industry and increased to \$106,590. There is also \$519,140, a net increase of \$271,340, for the enforcement of the United States Grain Standards Act; \$59,620 for the United States Warehouse Act; \$98,600 for the United States Cotton Futures Act; and \$4,000 for the act of August 31, 1916, to fix standards for Climax baskets and other containers for fruits and vegetables.

A net increase of \$71,000 is provided for the market news service as to fruits and vegetables, of which \$40,000 is made immediately available for work with crops in transit during the present fiscal year. There are also small increases for the market reports on live stock and meats, the studies of market grades and standards, the cotton standardization work, and for cooperation with the States in marketing studies and demonstrations.

The allotment for the Office of Farm Management is increased from \$225,810 to \$305,810, thereby allowing for a further extension of the farm-management surveys and the enlargement of some of the survey units. An item of \$5,000 carried for several years for studies of the utilization of logged-off lands is omitted.

An increase from \$75,000 to \$125,000 is provided for the Federal Horticultural Board, which administers the Plant Quarantine Act, to prevent if possible the introduction of the pink bollworm of cotton. This serious pest has recently been discovered in the Laguna district of Mexico and its dissemination is feared through importations of cotton and cotton seed from that country. Strict quarantine pro-

visions are authorized, as well as control measures in cooperation with the States in case infestation occurs.

The work of the remaining branches of the Department is continued on substantially the present basis, both as to funds and lines of work. The Bureau of Crop Estimates is granted \$323,452, an increase of \$7,016, mainly for the employment of additional field agents and specialists in truck and fruit crops. The Office of the Secretary receives \$412,010, in addition to the allotment of the Office of Farm Management already noted; the Division of Accounts and Disbursements, \$44,920; the Division of Publications, \$213,990; and the Library \$50,160. The Department is granted \$112,500, an increase of \$7,500, for the enforcement of the Insecticide Act; \$50,000, an increase of \$10,000, to continue and extend the demonstration work on reclamation projects, and \$137,500 for miscellaneous expenses. The allotment of \$143,689 is made for rent of buildings in the District of Columbia, an increase of \$20,000 over the present appropriation, and a joint Congressional committee is authorized to investigate the rental situation in Washington and the estimated cost of construction of sufficient Government-owned buildings to meet the Department's needs.

Among minor items of legislation not hitherto mentioned, the Department is authorized to loan, rent, or sell copies of its moving picture films, giving preference to educational institutions or associations for agricultural education not organized for profit. The President is authorized to extend the usual invitation to other nations to participate in the 1918 meeting of the International Farm Congress, which is expected to be held at Peoria, Illinois.

In a discussion of the appropriation act as a medium for Federal aid to agriculture, the fact should not be lost sight of that increasingly large sums are now available in other ways. Thus, what are known as the permanent and indefinite appropriations for the Department aggregate for the fiscal year \$17,235,000, or nearly three-fourths as much as the total carried in the act itself. The largest sources, namely, the Federal-aid Road Act, the meat-inspection provision, and the Extension Act, have already been referred to, the remaining funds being chiefly for payments to the States as their quota of the receipts from National Forests. There is also the appropriation for the Department printing and binding, this year aggregating \$600,000, which is carried in the appropriation bill for sundry civil expenses, not yet enacted for the fiscal year 1918.

Of the Federal funds expended outside the Department, the usual appropriation of \$2,500,000 will be available for agricultural education under the Morrill and Nelson acts, as well as the smaller grants for the rural education work for the United States Bureau of Edu-

cation, demonstration work among the Indians, the maintenance of the Federal Farm Loan Board, and the payment of the country's quota toward the support of the International Institute of Agriculture. To these has recently been added another large permanent enterprise through the passage of the Vocational Education Act. This measure, signed by President Wilson February 23, 1917, carries among other allotments an appropriation for the fiscal year 1918 of \$500,000 for cooperation with the States in secondary education in agricultural subjects, and an additional amount for the training of teachers, supervisors, and directors. It is hoped to present a summary of this important law in a subsequent issue.

Because of the indefinite nature of some of the appropriations, the precise total of the Federal funds for the benefit of agriculture during the year under review can not be predicted, but it is believed it will approximate \$50,000,000. Not all of this vast sum, it should be remembered, is expended exclusively for agriculture, for large sums are devoted to regulatory functions of direct service to the public as a whole. Yet it is an impressive showing, especially when it is recalled that it is a virtual doubling of the figures of even five years ago. The expansion in lines of work is even more significant, and indicates the broadened conception of the term agriculture and the legitimate field of the Federal Government in its development.

Progress has, of course, been especially noteworthy along extension lines and in attention to the problems of distribution. From this point of view, perhaps the most significant feature of this period is, as was said by Assistant Secretary Vrooman of the Department in a recent article, "that the Federal Government at last is meeting the farmer at least halfway, and has manifested not merely a willingness but a friendly desire to cooperate with him in the future in any constructive work that looks to the building up of our national prosperity on the basis of a permanently prosperous agriculture."

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY—AGROTECHNY.

**Chemical calculations**, R. H. ASHLEY (*New York: D. Van Nostrand Co., 1915, pp. X+276*).—The author has written this text-book for the needs of the student who will later find occupation in chemical laboratory work. The topics discussed are as follows: Ratios, approximate numbers, interpolation, heat, specific gravity, gas calculations, calculation of atomic weights and formulas, gravimetric analysis, volumetric analysis, and use of specific gravity tables and acid calculations. Many original problems are given in each chapter relating to the subject matter discussed.

**Chemical constitution and physiological action**, L. SPIEGEL, trans. and ed. by C. LUEDEKING and A. C. BOYLSTON (*New York: D. Van Nostrand Co., 1915, pp. V+155*).—This volume discusses the relation between chemical constitution and physiological action under the headings of general considerations, inorganic compounds, organic compounds of the aliphatic and aromatic series, and nitrogen compounds.

**The specificity of proteins and carbohydrates in relation to genera, species, and varieties**, E. T. REICHERT (*Amer. Jour. Bot., 3 (1916), No. 3, pp. 91-98*).—This article briefly reviews the material previously noted (E. S. R., 31, p. 804).

It is indicated that through these studies a strictly scientific basis for the classification of plants and animals has been found. "There are manifestly certain striking applications that are of the greatest fundamental importance in the study of phylogeny, mutations, reversions, sex, malformations, phenomena of heredity in general." The discovery of the existence of highly specialized stereoisomers has revealed the most remarkable and unsuspected phenomena of living matter, and one which leads directly to the constitutions of various forms of protoplasm and the peculiarities of vital phenomena that are dependent on these differences.

**The physiological relation of plant carotinoids to the carotinoids of the cow, horse, sheep, goat, pig, and hen**, L. S. PALMER (*Jour. Biol. Chem., 27 (1916), No. 1, pp. 27-32*).—In continuation of the work previously noted (E. S. R., 31, p. 273) the author reports the results of a study of the carotinoids in various animals.

It is concluded that a definite physiological relation exists in all species of animals between the pigmentation of tissue fat with carotinoids and the presence of these pigments in the blood serum. Those species whose tissue fat is colored with carotinoids (cow, horse, and hen) carry the pigments in the blood serum. Species whose tissue fat is characterized by being colorless (swine, sheep, and goat) carry only insignificant traces in the blood serum even under the most favorable conditions.

An abundance of carotin in the blood serum and in the tissue fat is not deemed a specific characteristic of the ruminants, as is indicated by its absence from the blood serum and tissue fat of sheep and goats and its presence in the horse.

The reaction between amino acids and carbohydrates as a probable cause of humin formation, M. L. ROXAS (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 71-93).—From a study of the effects of various amino acids and carbohydrates as a factor in humin formation during the hydrolysis of proteins, the author found that alanin, leucin, phenylalanin, and glutaminic acid are not important factors in humin formation. Prolin may, however, be involved in the humin formation under certain conditions. In digestion with 20 per cent hydrochloric acid plus sugar the proportion of nitrogen disappearing and responsible for humin formation was for tyrosin, 15 per cent; cystin, 3.1; arginin, 2.33; lysin, 2.62; histidin, 1.84; and tryptophan, 71 per cent. Xylose and fructose were generally more reactive than glucose.

Arginin, histidin, and lysin reacted with sugars more readily in weak acid or aqueous than in strong acid solutions. Arginin, histidin, and tryptophan reacted with a loss of their amino nitrogen, but tyrosin and cystin reacted without any such loss. It appears thus that it is not the amino group of either tyrosin or cystin that reacts with the carbohydrate to form melanin, but probably the OH group in the former and the sulphur linking in the latter.

A possible mode of reaction between the amino acids and the carbohydrates or some degradation product is suggested.

Experimental results are submitted in detailed tabular form.

Tyrosinase and deaminization, K. SCHWEIZER (*Tyrosinase et Désamination. Thesis, Univ. Geneva, Inst. Bot., No. 573 (1916), pp. 117*).—The study reported is considered under the following topics: History, distribution, preparation, properties, action, constitution, and synthesis of tyrosinase; general considerations of deaminization; deaminization by tyrosinase; deaminization by tyrosinase in the presence of phenol; deaminization by tyrosinase in the presence of chlorophyll; and deaminization under anaerobic conditions.

It is concluded that deaminization is not necessarily produced by hydrolytic enzymes, but very readily by oxidases, tyrosinase in particular. The existence of hydrolytic deaminases is rendered highly problematical. The cleavage products of deaminizations by tyrosinase are ammonia, carbon dioxide, and a fatty acid with one less carbon atom than the original substrate. In the animal organism tyrosinase is active in the formation of urea by the degradation of polypeptids and amino acids, not through simple hydrolysis but by oxidation.

A complete list of references to the literature cited is included.

The chymase of *Solanum elæagnifolium*.—A preliminary note, A. BODANSKY (*Jour. Biol. Chem.*, 27 (1916), No. 1, pp. 103-105).—The author has found a chymase in *S. elæagnifolium* (white horse nettle) the properties of which agreed in general with those of other vegetable chymases. It coagulates boiled natural milk without the addition of calcium chlorid, is more resistant to heat than rennin, and obeys the enzym laws in general.

The possible adoption of the enzym preparation by cheese makers as a substitute for rennet extract is indicated and will be further studied.

The preparation and properties of lead-chlor arsenate, artificial mimetite, C. C. McDONNELL and C. M. SMITH (*Amer. Jour. Sci.*, 4. ser., 42 (1916), No. 248, pp. 139-145, figs. 2).

Methods for chemical and microscopical diagnosis, F. A. STEENSMA (*Methoden der Chemische en Microscopische Diagnostiek. Amsterdam: Scheltema & Holkema, 1915, 3. ed., rev. and enl., pp. 157*).—This volume outlines methods for the examination of urine, urine sediment, blood, gastric contents, feces, sputum, pus, exudates and transudates, cerebrospinal fluid, semen, milk, specimens of hair and epithelial tissue, and concretions, and includes notes on the medico-legal examination of such material. Only those methods which

have been found to be perfectly reliable and comparatively simple to manipulate are described.

A new type of extractor, J. B. McNAIR (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, p. 838, fig. 1).—An original type of extractor which has been used successfully in extracting plant material with 86° Baumé gasoline and its manipulation are described in detail.

A comparison of the relative efficiency of laboratory reflux condensers, M. V. DOVER and J. W. MARDEN (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 834–836).—From a critical examination of the efficiency of various lengths of Liebig, Allihn, spiral, Hopkins, Davies, and Friedrichs condensers it has been demonstrated that in order to obtain comparable results the rate of drop back of the liquid must be in approximately equal weights per second. For such a condition it is necessary that the condenser tube be beveled so that the drop returns from one point only. The rate of boiling has very marked influence upon the efficiency of the condenser, as well as the bore and the narrowing at the tip or constriction anywhere in the tube. Such conditions tend to cause choking and consequently disproportionate great loss. For low boiling liquids the length of the condenser is a factor in its efficiency, especially in the Liebig type.

“In experiments where a long condenser can be conveniently used, the Liebig seems to be preferable, because it is a much less costly condenser and can be easily cleaned. Where a short condenser is required, the Friedrichs seems best. The short Liebig or Allihn can be used to advantage only when the rate of condensation is not greater than from 2 to 3 drops per second, or when some means is used, such as a glass-wool plug in the top of the condenser or a test tube inverted over the top of the condenser, to prevent too rapid a carrying away of the vapor by air currents.”

Extending the usefulness of a shaking machine, R. M. CHAPIN and J. M. SCHAEFFER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 10, pp. 921, 922, fig. 1).—The authors describe fittings which can be applied to a flask-shaking machine so that the machine can be used as a sieve shaker and a shaker for liquids in various other forms of containers.

Aeration method for ammonia, B. S. DAVISSON, E. R. ALLEN, and B. M. STUBBLEFIELD (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 10, pp. 896–899, fig. 1).—Experimental data are reported by the authors from the Ohio Experiment Station which show that ammonia can be determined by aeration over magnesium oxid.

The Folin tubes were found to be of little value at the rate of air flow (1,080 liters per hour) used in the experiments reported. For complete absorption of the liberated ammonia an absorbing tower in which the air could be completely scrubbed while passing through the absorbent was necessary. A modified tower with which complete absorption of rather large quantities of ammonia was possible in 2.5 hours is described.

The use of considerably smaller quantities of magnesium oxid than are commonly recommended was found to yield as satisfactory results.

It is indicated that a standard method of measuring the rate of aeration should be adopted so that results from various sources may be comparable.

Does vanadium interfere with the determination of phosphorus in soils when the phosphorus is weighed as magnesium pyrophosphate? R. A. GORTNER and W. M. SHAW (*Soil Sci.*, 2 (1916), No. 3, pp. 299–304).—A series of phosphorus determinations, using soil solutions to which known amounts of vanadium were added, the phosphorus being weighed as pyrophosphate after standing for 24 hours, are reported in detail. In no instance was any appre-

ciable interference by vanadium observed. The titrametric method for phosphorus was also unaffected by the presence of vanadium in amounts far in excess of those usually found in soils.

See also a previous note by Robinson (E. S. R., 34, p. 806).

Examination of a radio-active fertilizer, W. P. JORISSEN (*Chem. Weekbl.*, 13 (1916), No. 39, pp. 1055-1059, figs. 2).—The author reports the examination of a fertilizer which showed a radium content of  $0.14 \times 10^{-10}$  gm. per gram of dry material.

The apparatus and manipulation of the emanation method for determining radio-activity are described in detail.

The solubility of leucite in sulphurous acid, J. SCHROEDER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 779, 780).—Solubility tests of leucite of varying degrees of fineness in sulphurous acid indicate that the potash may be readily dissolved from the leucite rocks by this acid. The materials used varied in fineness from 0.5 to less than 0.1 mm., and the potash dissolved on the basis of  $K_2O$  present in the samples varied from 41.7 to 76.4 per cent.

The possibility of the industrial application of this procedure for the extraction of potash by using the smelter gases in the western part of the United States near regions where the leucite occurs naturally is indicated.

Report of the seventh convention of Dutch food chemists (*Chem. Weekbl.*, 13 (1916), No. 36, pp. 974-1009, fig. 1; *Pharm. Weekbl.*, 53 (1916), No. 36, pp. 1193-1230, fig. 1).—This report contains a short address by the chairman, a short report on the hydrogenation of oils, and analytical notes and data on methods of food analysis as recommended by the Dutch Chemical Society.

Improved apparatus for use in making acidity determinations of corn, H. J. BESLEY and G. H. BASTON (*U. S. Dept. Agr., Office Sec. Circ.* 68 (1916), pp. 4, fig. 1).—A modified procedure of the method by the authors, previously noted (E. S. R., 31, p. 525), is described. The procedure consists essentially of extraction with 80 per cent alcohol for 30 minutes with the use of an electric mixer, dilution of 25 cc. of the filtrate with 75 cc. of water, and titration with 1/100-normal alkali.

It is indicated that, while there is some variation in the results of acidity determinations by different methods, the electric mixer will extract from the corn in 30 minutes an amount of acid which, for all practical purposes, is comparable to the amount extracted in 80 per cent alcohol after 18 hours digestion.

An improved method for the detection of arachidic acid, R. H. KERR (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 10, p. 904).—A method for which the advantages of greater convenience, a lessening of the number of operations, a reduction of the amount of attention required, and the avoidance of the use of ether are claimed over the Renard method as adopted by the Association of Official Agricultural Chemists (E. S. R., 20, p. 512) is described.

The procedure consists of saponifying the oil with alcoholic potash and neutralizing excess alkali with acetic acid after saponification is complete. Fifty cc. of 5 per cent magnesium acetate is then added, and the mixture heated to boiling, cooled, and placed in a refrigerator at a temperature of from 10 to 15° C. until the next day. The solution is filtered, the precipitate washed twice with 50 per cent alcohol and three times with distilled water, and returned to the original flask. One hundred cc. of hot distilled water is then poured into the flask and sufficient dilute sulphuric acid added to decompose the magnesium salts. The flask and contents are heated until the acids form a clear layer, the flask is cooled, the acid solution decanted, and 100 cc. of hot water added to wash the fatty acids. After cooling, the solidified cake of acids is freed as far

as possible from water by draining, dissolved in 100 cc. of 90 per cent alcohol, and the arachidic acid separated by crystallization.

The procedure has been found capable of detecting 5 per cent of peanut oil in olive oil, cotton-seed oil, soy bean oil, and corn oil. No attempt, however, has been made to apply it for quantitative purposes.

**The determination of citric acid in milk,** R. KUNZ (*Arch. Chem. u. Mikros.*, 8 (1915), No. 4, pp. 129-133).—The following procedure for the determination of citric acid in milk, based on the test described by Stahre,<sup>1</sup> is described:

Fifty cc. of milk is treated with 10 cc. of dilute sulphuric acid (1:1) in a 200-cc. volumetric flask, and thoroughly shaken. Two cc. of a 40 per cent potassium bromid solution and 20 cc. of a solution of phosphotungstic acid are then added and the mixture made up to volume with distilled water. After thorough mixing the precipitate is separated by filtration, 150 cc. of the perfectly clear filtrate is transferred to an Erlenmeyer flask, 25 cc. of freshly prepared saturated bromin water added, and the mixture then placed for about five minutes on the water bath at a temperature of from 48 to 50° C. Ten cc. of a 5 per cent potassium permanganate solution is then slowly added from a pipette in a continuous stream with constant shaking of the mixture. The pentabrom acetone which is precipitated is filtered and treated as previously described for the determination of citric acid in wine.<sup>2</sup>

A correction for the volume of the protein precipitated in the procedure described for milk is necessary, and was found by the author to be such that 150 cc. of the clear filtrate used was equivalent to 38.2 cc. of the original sample. Analytical data obtained from a number of samples of normal milk examined showed a variation of from 0.1553 to 0.173 gm. of citric acid per 100 cc. of milk.

In two samples of human milk examined, 0.0618 and 0.0439 gm. of citric acid, respectively, were found per 100 cc. of milk.

Comparative determinations of fresh and soured milk indicated that the citric acid gradually disappeared with the aging of the sour milk. This destruction of the acid is deemed to be due rather to microbial action than to the enzymes contained in the milk. An examination of freshly prepared 24-, 48-, and 72-hour-old Bulgarian sour milk (yoghourt) showed no destruction of the citric acid present.

**The determination of gum and pectin in filter residues [in the manufacture of sugar],** T. VAN DER LINDEN (*Meded. Proefstat. Java-Suikerindus.*, 6 (1916), No. 7, pp. 205-219).—After some preliminary experimentation the following modified procedure for pectin determination was evolved:

Twenty gm. of the residue is digested for one-half hour with from 200 to 400 cc. (depending on the nature of the material) of a mixture of alcohol and hydrochloric acid (100 parts 95 per cent alcohol and 20 parts hydrochloric acid, specific gravity 1.09). The mixture is then filtered and washed with warm alcohol, the residue repeatedly extracted with from 300 to 400 cc. of warm water, the extracts evaporated to about 40 cc. on the water bath, and, on cooling, the pectin precipitated with a mixture of 300 cc. of 95 per cent alcohol and 60 cc. of hydrochloric acid, specific gravity 1.09. After several hours the precipitate is filtered through an ashless paper, dried at 105° C., and weighed. The material is then ashed, again weighed, and the difference calculated as pectin.

**A study of the sirup precipitate in white sugar manufacture,** C. E. COATES and L. C. SLATER (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 789-792).—The authors have examined the sirup precipitate obtained from two factories, in one of which phosphoric acid was used in the clarification and the other in which no acid was used.

<sup>1</sup> Ztschr. Analyt. Chem., 36 (1897), No. 3, p. 195.

<sup>2</sup> Arch. Chem. u. Mikros., 7 (1914), No. 6, pp. 285-299.

The precipitate from the factory using no phosphoric acid consisted essentially of 40 per cent organic matter, 30 per cent silica, and the remainder of calcium phosphate, copper, iron, and aluminum salts. The other precipitate contained 25 per cent organic matter, 30 per cent silica, and 25 per cent calcium phosphate, the remainder being copper, iron, and aluminum salts.

Detailed analytical data are submitted.

The composition of sound and frozen lemons with special reference to the effect of slow thawing on frozen lemons, H. S. BAILEY and C. P. WILSON (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 10, pp. 902-904).—Analytical data obtained from samples of fruit damaged in southern California by the freeze of January 6, 1913, show that lemons that remained on the trees after being frozen retained less juice and considerably less acid than the fruit picked immediately after being frozen and stored at a temperature of from 45 to 50° F. A rapid decrease in specific gravity due to the loss of juice and acid and the formation of thick, puffy skins, dried-up cells, and hollow centers was observed in the fruit left on the trees. Somewhat less juice was retained by the fruit picked immediately after being frozen and stored under ordinary packing-house conditions than by unfrozen fruit. The composition was practically the same, however, and in weight and appearance the slowly thawed lemons compared well with normal fruit.

See also a previous note by Young (*E. S. R.*, 34, p. 502).

The production of sweet-orange oil and a new machine for peeling citrus fruits (*U. S. Dept. Agr. Bul.* 399 (1916), pp. 19, figs. 10).—This bulletin consists of two parts.

I. *Possibility of the commercial production of sweet-orange oil from waste oranges*, S. C. Hood and G. A. Russell (pp. 1-12).—The investigation reported shows that the extraction of sweet-orange oil is a commercial possibility in the United States. A good quality of oil was produced by steam distillation in vacuo, but an excellent quality and a larger quantity of oil was secured by pressing the pulped peel from culls, drops, and inferior grades of fruit. An average yield of from 4 to 5 oz. of oil was obtained from 100 lbs. of fruit, the cost for this extraction being about 15 cts. The net returns from a standard field box are deemed to be from 32 to 44 cts.

II. *A detailed description of a new machine for peeling citrus fruits*, S. C. Hood (pp. 13-19).—The construction and manipulation of a machine which, manipulated by one man, can remove the peel from 2 tons of oranges or from 3.5 tons of grapefruit in one hour is described in detail. The peel comes from the machine in a finely divided condition suitable for the extraction of the oil, and the peeled fruit is in a condition suitable for use in the manufacture of various fruit products. The machine, as described, can be used for oranges or lemons, and with slight modifications also for limes or grapefruit.

The effect of curing on the aromatic constituents of vanilla beans, F. RABAK (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 9, pp. 815-821, figs. 3).—Experimental data reported indicate that the curing process as commercially applied at present to vanilla beans is unnecessarily long and extended, requiring on the average several months for the transformation.

Laboratory experiments have demonstrated that the beans can be cured in a much shorter time by means of a less tedious process. The simplification of the process is rather to the advantage than to the detriment of the aromatic constituents of the cured beans. It is suggested that, in order to produce uniformity in the composition of the beans and thereby to insure more uniform extracts, the beans should be imported green and cured.

“While the amount of vanillin in the beans was not increased appreciably, as compared with commercial beans, it may be stated with assurance that the

beans cured in the laboratory were in most cases superior in vanilla resins and coloring matter. This is significant since vanilla resins and coloring matter are considered important adjuncts to the quality of vanilla beans. The superior flavor of the extracts prepared from the laboratory cured beans may therefore be ascribed to the resinous constituents. A considerable proportion of the vanilla resins are left unextracted when the menstruum is less than 65 per cent alcoholic strength."

The curing of the green beans at room temperature, with or without previous treatment with water at 90° C. for a short period of time produced beans of the best quality, as judged by the flavoring extracts prepared from the samples.

Notes on the production of oil of citronella, A. W. K. DE JONG (*Teysmannia*, 27 (1916), No. 4-5, pp. 246-252 figs. 2).—These pages contain notes on the preparation of the grass for distillation, the distillation process, and the separation of the oil and water in the crude product.

Analytical data submitted show an increase of 44 per cent in yield of oil from grass which had been dried for ten days over that yielded by fresh material. Cutting the grass in lengths of from 3 to 5 cm. (1.2 to 2 in.) was also found to increase the yield. The residue from the distillation on analysis showed moisture 15.8 and nitrogen 2 per cent. Its value as a fertilizing material is indicated.

The use of bark for paper specialties, O. KRESS (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 10, pp. 883-886).—Experiments on the use of hemlock and oak bark used in conjunction with rag stock for the manufacture of roofing felts, etc., the use of hemlock and oak bark with unbleached sulphite pulp for a hanging paper, and the use of spruce and balsam for wall boards are described. Suggestions as to further possible uses of such stock are made and the economic importance indicated.

## METEOROLOGY.

The effect of climate and soil upon agriculture, R. R. SPAFFORD (*Univ. [Nebr.] Studies*, 16 (1916), No. 1-2, pp. 91-113, figs. 26).—This article is based primarily upon farm-management studies in 16 counties in Nebraska, but also takes into consideration certain general observations extending over a wider area of the surrounding region.

From the studies in Nebraska it is concluded that the most important natural factors determining the character of farm business in that State are moisture and soil texture. "In general cultivated plant growth per acre varies quite in harmony with the growth of native vegetation," and this is determined largely by the rainfall. There is a "rapid change from favorable to adverse conditions after passing the 24-in. line of rainfall. The number of acres required to pasture a horse or cow may be used as a rough measure of this change. To provide five months' pasture for a mature animal in western Nebraska requires about four times the number of acres necessary in eastern Nebraska. From this fact alone it is not out of reason to infer that a decrease in the effective value of moisture reduces the available pasture growth from 1 to about one-fourth." In one case studied the effective value of moisture is such that the total usable pasture growth is only about one-fourth that in another, and it was found that the size of the farm in the first case was at least four times that in the second.

These conclusions, though based largely on Nebraska data, are not considered local in bearing. "Moisture problems from southern Texas to the head of the Mississippi River are closely related. To the south they are influenced by high temperature, while to the north they are modified by low temperature. From the head of the Mississippi northwest into Saskatchewan and Alberta a lobe of favorable summer temperature determines, to a large extent, the boundaries of

the Canadian agricultural area recently opened. In the southern part of this lobe the problems of low temperature are more commonly blended with problems of low rainfall than is true farther north. . . . The distribution of native vegetation relative to these lines is very marked. . . . The natural factors which give such striking characteristics to the distribution of native vegetation give equally striking characteristics to the distribution of people and the organization of farm business."

The probable growing season, W. G. REED (*U. S. Mo. Weather Rev.*, 44 (1916), No. 9, pp. 509-512, fig. 1).—From a study of data relating to the length of the frostless period from 1872 to 1914 at Keokuk, Iowa, it is concluded that in general "the chance of killing frost falls to 10 per cent between 10 and 30 days after the average date of the last killing frost in spring; in the fall the corresponding difference is about the same. In general any station has a dispersion in spring similar to that in fall."

Weather insurance, W. G. REED (*U. S. Mo. Weather Rev.*, 44 (1916), No. 10, pp. 575-580).—In continuation of previous discussions bearing on this subject (*E. S. R.*, 35, p. 617), the author maintains that the cost of losses from unfavorable weather conditions should be carried as an annual charge against the farm business. From a study of extensive data relating to the frequency distributions of injurious spring and fall frosts in Kansas and Ohio he concludes that sufficient data are now available "to enable determinations of the chance of frost at any time to be made for nearly all the agricultural regions of the United States. Although other phenomena do not show the same frequency distributions as critical frost dates, the distributions for many of these phenomena have been partially investigated and the mathematical studies already completed indicate that the chance of any weather condition at all can be determined with more or less accuracy. Therefore practicable insurance against any unfavorable weather depends solely upon the determination of the hazard and a sufficient number of properly distributed risks."

Condensed meteorological reports, C. C. GEORGESON (*Alaska Stas. Rpt.* 1915, pp. 93-100).—Tabular monthly summaries are given of observations on temperature, precipitation, and condition of the weather at 25 stations in different parts of Alaska during 1915.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and J. S. SIMS (*Massachusetts Sta. Met. Buls.* 335-336 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during November and December, 1916, are presented. The general character of the weather for November is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

*Pressure*, reduced to freezing and sea level (inches).—Maximum, 30.64, January 8; minimum, 28.76, February 25; mean, 30.006. *Air temperature*, in ground shelter (degrees F.).—Maximum, 95.5, August 22; Minimum, —16, February 15. *Humidity*.—Mean dewpoint, 38.4; mean relative humidity, 80.3. *Precipitation*.—Total rainfall or melted snow, 45.61; number of days on which 0.01 in. or more rain or melted snow fell, 126; total snowfall, 59.5 in. *Weather*.—Total cloudiness recorded by sun thermometer, 2,418 hours, or 53 per cent; number of clear days, 121. *Bright sunshine*.—Number of hours recorded, 2,036, or 47 per cent. *Wind*.—Prevailing direction, west; total movement, 52,450 miles; maximum daily movement, 519 miles, February 28; minimum daily movement, 0 miles, December 4; maximum pressure per square foot, 25 lbs., January 23, west. *Dates of frost*.—Last, May 19; first, September 17. *Dates of snow*.—Last, April 14; first, November 15.

**Monthly Weather Review** (*U. S. Mo. Weather Rev.*, 44 (1916), Nos. 9, pp. 499-545, pls. 12, figs. 7; 10, pp. 547-610, pls. 13, figs. 22).—In addition to weather forecasts, river and flood observations, and seismological reports for September and October, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during September and October, 1916; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

[Observations on aerology] (*U. S. Mo. Weather Rev.*, Sup. 3 (1916), pp. 67, pls. 8, figs. 11).—This supplement contains the following articles: Sounding Balloon Ascensions at Fort Omaha, Nebr., May 8, 1915; Meteorological Observations on Board the U. S. Coast Guard Cutter Seneca, April to July, 1915; The Drexel Aerological Station; and Free-air Data at Drexel Aerological Station, October, November, and December, 1915.

Elementary notes on least squares, the theory of statistics and correlation, for meteorology and agriculture, C. F. MARVIN (*U. S. Mo. Weather Rev.*, 44 (1916), No. 10, pp. 551-569, figs. 18).—"An effort has been made in this paper to outline in a general way the essential principles of the methods of least squares and the theories of statistics and correlation, with reference to their application in the analysis and presentation of climatic data and their utilization in the solution of problems of agricultural meteorology. While a considerable knowledge of mathematics is essential to a complete mastery of all the methods, processes, and relations, nevertheless an elementary knowledge and a little study are sufficient to enable anyone to carry out the relatively simple routine and systematized calculations that are necessary to bring out all the

facts. Examples of these computations have been shown with considerable and seemingly all necessary fullness."

A bibliography of the more recent literature on this subject is given.

### SOILS—FERTILIZERS.

**Soil survey of the Ukiah area, California, E. B. WATSON and R. L. PENDLETON** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 53, pls. 5, figs. 2, map 1*).—This survey, made in cooperation with the California Experiment Station, and issued December 16, 1916, deals with the soils of an area of 193,920 acres in southeastern Mendocino County, Cal., which includes several arable valleys and a part of the Coast Range Mountains. The drainage of the hills is well established, and that of the valley floors, with some few exceptions, is generally complete.

"The soils of the Ukiah area fall into three general groups [as follows]: (1) Residual soils, (2) soils derived from old valley-filling material, and (3) soils derived from recent alluvial deposits." Including rough mountainous land and river wash, 20 soil types of ten series are mapped, of which rough mountainous land covers 67.7 per cent and Pinole gravelly loam 11.4 per cent of the area.

**Soil survey of Washington County, Georgia, R. A. WINSTON, J. H. AGEE, J. A. KERR, and M. E. CARR** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 39, fig. 1, map 1*).—This survey, made in cooperation with the Georgia State College of Agriculture, and issued December 15, 1916, deals with the soils of an area of 428,160 acres in the Coastal Plain region of east central Georgia, the topography of which ranges from undulating to rolling. The uplands are naturally well-drained, while the first bottom lands are usually low, flat, and poorly drained.

The soils are of sedimentary origin and range from loose incoherent sands to fairly heavy silty clays. Including meadow, 20 soil types of 10 series are mapped, of which the Norfolk sandy loam, Orangeburg sandy loam, Norfolk sand, meadow, and Ruston sandy loam cover 21.4, 17.7, 13.5, 11.1, and 10.2 per cent of the area, respectively.

**Soil survey of Wilkes County, Georgia, D. D. LONG** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 35, fig. 1, map 1*).—This survey, made in cooperation with the Georgia State College of Agriculture, and issued December 18, 1916, deals with the soils of a well-drained area of 306,560 acres in the Piedmont plateau province in northeastern Georgia. The topography in general is gently rolling.

Most of the soils of the county are of residual origin and are heavy, belonging to the silty clay loam, clay loam, and clay classes. A considerable area of soils of sandy loam, fine sandy loam, and loam texture also occurs. Including meadow, 18 soil types of five series are mapped, of which the Cecil clay loam and sandy loam cover 38.5 and 18.5 per cent of the area, respectively.

**Soil survey of Coahoma County, Mississippi, F. Z. HUTTON ET AL.** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 29, fig. 1, map 1*).—This survey, made in cooperation with the State of Mississippi and issued December 19, 1916, deals with the soils of an area of 357,120 acres in the Mississippi Delta region in northwestern Mississippi. In spite of the numerous streams, large areas in the county have poor drainage.

The soils consist entirely of alluvial deposits, and the more important are divided into two groups, (1) having heavy clay subsoils, and (2) having light-textured subsoils. Including meadow, overwash, and excavated land, 12 soil types of three series are mapped, of which the Sharkey clay, Sharkey silty clay

loam, and the Sarpy very fine sandy loam cover 52, 14.3, and 10.4 per cent of the area, respectively.

**Soil survey of Dickey County, North Dakota, T. M. BUSHNELL ET AL.** (*U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 56, pls. 2, fig. 1, map 1*).—This survey, made in cooperation with the North Dakota Experiment Station and issued November 24, 1916, deals with the soils of an area of 730,880 acres in southern North Dakota which physiographically comprises “(1) an old, sandy lake bed; (2) level, treeless prairie; and (3) a high, rolling plain. . . . On the plateau and in the Lake Dakota basin regional drainage has not been established. The remainder of the county is imperfectly drained.”

The soils of the county are derived from glacial drift. Including rough broken land, 28 soil types of 10 series are mapped, of which the Barnes loam and silt loam cover 31.5 and 18.8 per cent of the area, respectively. “The Barnes series predominates east of the Missouri Plateau, and comprises much of the best farming land in the county.”

**The loess soils of the Nebraska portion of the transition region.—V, The water-soluble constituents, F. W. UPSON, J. W. CALVIN, and G. H. BROTHER** (*Soil Sci., 2 (1916), No. 4, pp. 377-386, fig. 1*).—An investigation conducted at the Nebraska Experiment Station on the water-soluble material in soils dealt with in previous papers by Alway et al. (*E. S. R., 35, pp. 809, 810*) is reported.

It was found that “in general the water-soluble material in the loess soils of the Nebraska portion of the transition region is low. The average total water-soluble material is quite uniformly distributed as to area, the inorganic material increases with the aridity, whereas the volatile material decreases with increasing aridity. The water-soluble bicarbonates decrease from west to east and follow the total carbonates in this respect. The water-soluble chlorids and sulphates as well as calcium and magnesium are quite uniformly distributed and follow the distribution of the total amounts of these constituents in these same soils. The water-soluble potassium is highest in the western areas and lowest in the eastern areas. In the extreme eastern area it decreases from the surface downward, whereas in the western area the reverse is true. In this respect it follows the citric-acid-soluble potash and not the total potash, which is quite uniformly distributed. The water-soluble phosphates show no very regular distribution.”

**Factors affecting the evaporation of moisture from the soil, F. S. HARRIS and J. S. ROBINSON** (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 10, pp. 439-461, figs. 17*).—The studies reported in this article were made at the Utah Experiment Station with loam, sand, clay, and muck, mostly in small tin plates and copper vessels 8 in. in diameter and 4 in. deep, but also in Petri dishes, long galvanized iron tanks, and deep cylindrical galvanized cans. An attempt was made to eliminate the factor of capillarity and to confine the study entirely to evaporation and various factors affecting it, including the initial quantity of soil moisture, humidity of the air, wind velocity, sunshine, temperature, size of soil particles, mulches, compacting the soil, method of applying water, and the presence of soluble salts. The experimental methods are described in detail.

It was found that “evaporation of moisture increases with the initial quantity in the soil. The increase is not so great with the higher percentages as with the lower, and there seem to be a number of critical points where the rate of loss changes rapidly. The rate of evaporation from a moist soil is very rapidly decreased as the humidity of the air is increased. Air currents greatly increase evaporation; but after about a certain wind velocity is reached the rate of evaporation is only slightly increased by increasing the wind velocity.

For the sizes investigated, evaporation was higher from the finer soil particles than from the coarser when both are completely saturated.

"Reducing the intensity of sunshine greatly reduces the rate of evaporation. Slight changes in temperature have a marked effect on evaporation. A thin mulch, if kept dry, is effective in reducing evaporation. Dry mulches, composed of fine particles, seem to be less effective than if composed of coarser particles. Compacting the surface of the soil increases evaporation. Dissolved salts in high concentrations reduce the evaporation of moisture from soils."

A list of 21 references to literature bearing on the subject is given.

Keep our hillsides from washing, A. R. WHITSON and T. J. DUNNEWALD (*Wisconsin Sta. Bul.* 272 (1916), pp. 18, figs. 14).—This bulletin deals with the extent and bad results of erosion on Wisconsin soils and describes preventive measures applicable to conditions of the State, including tillage, alternation of crops on sidehills, use of horizontal channels and terraces, protection of ravines and watercourses with stones and grass roots, gradual removal of trees from wooded hillsides, and the use of sidehill land for pasture.

Protozoa, as affecting bacterial activities in the soil, S. A. WAKSMAN (*Soil Sci.*, 2 (1916), No. 4, pp. 363-376).—Experiments conducted at the New Jersey Experiment Stations on the interaction between protozoa and bacteria in a clay soil and a light loam soil are reported.

It was found that the presence of protozoa seemed to check the bacterial numbers, which were found to be smaller in the soils where the protozoa were present than in the corresponding soils where they were absent. The ammonifying efficiency of the soil did not follow the changes in bacterial numbers.

Heating the soil at 65° C. for five hours destroyed the protozoa in all instances but one and greatly reduced the bacterial numbers; but when the proper amount of moisture was added and the soils were allowed to incubate for 30 days, the bacterial numbers increased to almost three times those of the check. There was a corresponding increase in ammonia production in the soil.

The action for 48 hours of 4 per cent toluene, which was then allowed to evaporate for 48 hours, killed the ciliates, but not the flagellates; this treatment also reduced the bacterial numbers, but they at once increased after the toluene was allowed to evaporate. The action of toluene and heat was greatest upon soils having a high content of organic matter, whether the protozoa were active or not.

The light loam soils kept out of doors gave higher bacterial numbers and higher ammonifying efficiency than those kept under laboratory temperatures, and the latter gave higher numbers and ammonifying efficiency than those kept at 30°. The soils with optimum moisture content gave in the main higher bacterial numbers and ammonifying efficiency than those of higher moisture content.

Nitrification in semiarid soils, I. W. P. KELLEY (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 10, pp. 417-437).—Previous investigations on this subject are briefly reviewed and laboratory studies at the California citrus substation of the relation of the concentration of nitrogenous materials and the period of incubation to the rate of nitrification are reported.

The results of the investigations showed that the amounts of nitrate formed from dried blood, bone meal, or ammonium sulphate during 4 weeks' incubation varied greatly with the amount of nitrogenous materials employed. When 1 per cent of dried blood was used (the proportion commonly employed in conventional nitrification studies) the nitrifying activity was found to be feeble or even negative in certain soils in which 1 per cent of bone meal and from 0.2 to 0.3 per cent of ammonium sulphate underwent active nitrification. When

low concentrations of dried blood such as are used in the field were employed, active nitrification took place in every case, and when equal amounts of nitrogen were added it was found that the yield of nitrate was quite similar whether the nitrate had been derived from dried blood, bone meal, or ammonium sulphate. High concentrations of bone meal furnishing amounts of nitrogen equivalent to that supplied by 1 per cent of dried blood inhibited nitrification in the same way as the dried blood. It was found that the inability to nitrify 1 per cent of dried blood was not confined to any one type of soil nor to soils low in organic matter.

"The effects produced by the addition of alkali salts varied greatly when different concentrations of nitrogenous materials were employed. In a given soil a concentration of 0.05 per cent of sodium carbonate was distinctly toxic to the nitrification of 1 per cent of dried blood, while as high a concentration as 0.4 per cent produced no effects on the nitrification of 0.1 per cent of dried blood. Likewise, 0.1 per cent of sodium carbonate was toxic to the nitrification of 0.15 per cent of ammonium sulphate, and markedly stimulating when 0.0625 per cent of ammonium sulphate was used. Similar statements may be made with regard to the effects of sodium sulphate.

"The results also show that widely different conclusions may be drawn from laboratory experiments when different periods of incubation are used.

"Nitrites were found to accumulate in large amounts where excessive amounts of nitrogenous materials were employed. In some cases the nitrite content greatly exceeded the nitrate content after an incubation period of several weeks. Likewise, the addition of alkali salts may suppress nitrate formation, while at the same time permitting nitrite formation to proceed actively."

The author concludes as a result of these investigations "that the methods now employed by many students of nitrification, in which high concentrations of nitrogenous materials are added and the nitrate determined at a fixed interval of time, are not only unsatisfactory, but that the results thus obtained are likely to be more misleading than informing." He therefore recommends that the activities of nitrifying organisms be studied in an environment as nearly similar to that of the field as possible.

A bibliography of literature bearing on the subject is given.

**The nitric nitrogen content of the country rock: A contribution regarding the origin of niter spots in certain western soils,** R. STEWART and W. PETERSON (*Soil Sci.*, 2 (1916), No. 4, pp. 345-361, pl. 1).—Experiments conducted at the Utah Experiment Station with samples of Utah and Arizona soils are reported, from which results were obtained similar to those obtained in previous work (E. S. R., 32, p. 28) with Utah, Colorado, and Wyoming soils.

It is concluded that "the nitrates of the niter spots of the cultivated soils are derived from the preexisting accumulations occurring in the adjacent country rock and transported by the movement of underground water, brought to the surface by exposure of the rock outcrop, and there deposited by the evaporation of the water. The brown color of the niter spots is due to the solvent and decomposing action of the nitrates on the old organic compounds of the soil, the source of which, like the nitrate, is in the shale and sandstone of the area, which is coal and oil bearing."

It is further pointed out that "characteristic niter spots may be produced artificially in the laboratory with a rich greenhouse soil and an excess of sodium nitrate. They are produced equally as well in soil rendered sterile by treatment with a saturated solution of mercuric chlorid or 5 per cent solution of carbolic acid."

On the distribution of phosphorus in a vertical section of bluegrass soil, A. M. PETER (*Soil Sci.*, 2 (1916), No. 4, pp. 387-393, figs. 2).—The chief object of this paper, prepared at the Kentucky Experiment Station, is to draw attention to the peculiar distribution of the phosphate in vertical soil sections taken from the experiment station farm at Lexington and to point out that it corresponds strikingly to the distribution of phosphate in the phosphatic limestone beds of the vicinity. It increased from 0.72 per cent at a depth of 1 ft. to 7.8 per cent at a depth of 6 ft. and thereafter decreased, being 2.02 per cent at a depth of 7 ft.

Nature of the sulphur in moorland soils injurious to plant growth and subterranean structures, W. THÖRNER (*Ztschr. Angew. Chem.*, 29 (1916), pp. 233-236; *abs. in Jour. Soc. Chem. Indus.*, 35 (1916), No. 15, p. 855; *Chem. Abs.*, 10 (1916), No. 20, p. 2606).—The so-called reactive sulphur in moor soils, which is injurious to both plant growth and cement in underground foundations, was found to occur not only as pyrites but also in the free state and in organic combination. Its destructive action is ascribed to the production of sulphuric acid by atmospheric oxidation in the presence of moisture. Finely divided sulphur mixed with moist sand or peat on a filter underwent slow oxidation as the water evaporated, and similar conditions are assumed to exist in peaty land containing sulphur on exposure to the atmosphere. An energetic oxidation of finely divided sulphur in aqueous suspension was observed during the electrolysis of the water.

Field tests of fertilizer action on soil aldehydes, J. J. SKINNER and C. F. NOLL (*Jour. Amer. Soc. Agron.*, 8 (1916), No. 5, pp. 273-298, pls. 5, fig. 1).—In an extension of work previously reported (*E. S. R.*, 31, p. 620; 32, p. 619), experiments conducted under a cooperative agreement between the U. S. Department of Agriculture and the Pennsylvania Experiment Station are reported. The purpose was to study the effects of vanillin and salicylic aldehyde on an acid silty clay loam soil at Arlington, Va., and a productive loam soil at the Pennsylvania Station, and the influence of lime and fertilizers on the action of these compounds.

It was found in a two years' field test that vanillin and salicylic aldehyde were harmful to cowpeas in the silty clay loam soil. The harmful effect of vanillin was lessened by sodium nitrate and that of salicylic aldehyde by acid phosphate. The effects of both vanillin and salicylic aldehyde were overcome by liming the soil. These field results are in harmony with the effect of fertilizer salts on the behavior of these compounds in water culture solution.

Vanillin and salicylic aldehyde were found in the silty clay loam soil several months after they were applied and after the end of the crop season. On the plats fertilized with sodium nitrate the vanillin had been changed or destroyed and did not remain as such to have its effect on the crop. Neither vanillin nor salicylic aldehyde was found to remain in the limed soil. The oxidizing power of the Arlington soil was checked by both vanillin and salicylic aldehyde, and this lessened oxidation was increased by fertilizers and by lime.

Vanillin and salicylic aldehyde had only a slight harmful effect on the productive loam soil. Again the harmfulness of vanillin was ameliorated by sodium nitrate and that of salicylic aldehyde by acid phosphate, and on limed soil the aldehyde compounds had no, or only slight, harmful effects. None of the added aldehydes remained in the soil in any of the plats at the end of the growing season. This is taken to indicate "that organic substances of this nature do not persist in this soil and consequently could have little or no effect on crop growth. This experiment demonstrates that such organic substances as aldehydes can exist in one soil and have their effect on growth,

while in another soil they are destroyed by oxidation or other life processes of the soil and do not remain to have an influence on soil productivity."

Soil fertility (*North Dakota Sta. Rpt. 1916, pp. 4, 5*).—A comparison of rotted stable manure with fresh manure and a combination of fresh manure and steamed bone meal gave results confirming those reported in Bulletin 100 (E. S. R., 28, p. 338).

"Four years' data from the milling of the wheats from lands treated with rotted manure, with fresh manure, with combination of fresh manure and steamed bone meal, and without treatment of any character, do not show striking differences that could be attributed to the use of manures. Cost data for the trial indicate that potassium and phosphorus fertilizers can not as yet be profitably used on the black clay soil."

Plat experiments comparing steamed bone meal, acid phosphate, and raw rock phosphate, in which stable manure and crop residues were also added to the soil, showed that on the basis of four-year averages "the commercially fertilized plats have not given a larger gross income than the plats on which stable manure was used. If the cost of the phosphorus fertilizer is deducted from the total income received from crops, a less return was obtained than from the manured plats. The income derived from the various treatments was nearly uniform. No form of phosphorus yielded markedly superior returns in this trial. Comparatively, acid phosphate made a slightly better showing than steamed bone meal or rock phosphate."

The use of fertilizers to increase crop production, E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 9, pp. 5-9, figs. 2*).—This is a brief note based on experience at the substation on the use of fertilizers and manure and especially on the value of manure as compared to other fertilizers. Experiments with potatoes, kale, mangels, and corn on muck, sandy loam, and shot clay soils showed that in all cases manure alone at the rate of 15 tons per acre produced greater increases in yield than sodium nitrate, superphosphate, potassium sulphate, ground lime rock, gypsum, and a complete fertilizer applied at respective rates of 100, 200, 200, 4,480, 200, and 450 lbs. per acre.

Improvement of hill and peaty pastures (*Univ. Col. N. Wales, Bangor, Dept. Agr. [Pub.] 3 (1915), pp. 2-6*).—Experiments on the treatment of poor pasture on hilly loam soil and on acid and neutral peat soils are reported. Seven  $\frac{1}{4}$ -acre plats were used, the treatment per acre being as follows: No manure, 1,000 lbs. of basic slag, 1,000 lbs. of ground Gafsa phosphate, 600 lbs. of superphosphate, 600 lbs. of superphosphate and 1 ton of ground lime, 1 ton of ground lime, and 3,600 lbs. of ground limestone. Each plat received in addition to the treatment mentioned, 150 lbs. of potassium sulphate or 600 lbs. of kainit.

The results indicated that basic slag is likely to produce at least as good a result as any other manure or mixture of manures on these soils. Gafsa phosphate (raw mineral phosphate) produced almost as good an effect as basic slag on acid peat soils. In no case was a return given by potash manure at all commensurate with its cost, the effect produced being negligible in almost every case. Lime and ground limestone had practically no effect, although in many cases the soil was acid.

The necessity for guano in national agriculture (*Las Necesidades de Guano de la Agricultura Nacional. Lima: Compañía Admin. Guano, 1916, pp. 432, pls. 85*).—This report deals with Peruvian agriculture with special reference to the use of guano as a fertilizer.

Factors affecting the absorption and distribution of ammonia applied to soils, R. C. COOK (*Soil Sci., 2 (1916), No. 4, pp. 305-344, figs. 7*).—Experiments

conducted at Rutgers College with typical New Jersey soils, including sand, sandy loam, loam, silt loam, and clay soils, on the absorption and distribution of ammonia applied to soils and on factors influencing the same are reported. Fifty gm. of soil was shaken for one minute with 200 cc. of a 1/100-normal ammonium sulphate solution and then allowed to stand, after which the ammonia was distilled off from a filtered portion.

It was found that New Jersey soils presented a wide range of absorptive capacity for ammonia, the smallest absorption being observed in the sand soil and the largest in the sandy loam soil. The presence of calcium oxid in soils seemed to exert a greater influence on absorption than any other factor, first increasing and then decidedly decreasing it. In general, mechanical and chemical composition, hygroscopicity, etc., all had some effect on absorption. To a certain extent, the absorption of ammonia followed the percentage of combined iron and alumina, calcium oxid and carbon dioxide, as well as the organic matter and physical properties of the soil. The presence of colloids and conditions which favor them increased the absorptive power of the soil, while the presence of potash or acid phosphate, either alone or in combination, reduced it.

The distribution of applied ammonia in soils was also quite variable and seemed to be a function of the absorption. In light soils the ammonia quickly found its way into the deeper layers unless there was a supply of CaO present; in heavier soils most of the ammonia was held in the surface 3 or 4 in. A slightly alkaline reaction was beneficial to the conservation of ammonia. Calcium carbonate had little effect upon the distribution of ammonia in soils, while the addition of potash or acid phosphate tended to lower the mean distribution. The ammonia remained nearer the surface of the soil the greater the absorptive capacity. Everything else being equal, ammonium sulphate should be applied shallower in light than in heavy soils."

A list of 35 references to literature bearing on the subject is appended.

Investigation and valuation of crude calcium cyanamid, P. LIECHTI and E. TRUNINGER (*Chem. Ztg.*, 40 (1916), pp. 365, 366; *abs. in Jour. Soc. Chem. Indus.*, 35 (1916), No. 11, p. 647).—A chemical method for determining the nitrogen content of calcium cyanamid is described.

In six specimens of calcium cyanamid a maximum cyanamid-nitrogen content of 0.5 per cent was found, whereas the nitrogen present as dicyandiamid ran to more than 7 per cent. As it was thought that the dicyandiamid can act as a plant poison under certain conditions, pot experiments on wheat were made to compare the action of these abnormal specimens with that of the normal fertilizer. These showed that the former were distinctly injurious to the yield of grain and to a lesser extent to the yield of straw.

During a 3-months' storage of calcium cyanamid in an atmosphere saturated with moisture, the original cyanamid present was almost completely converted into dicyandiamid. On the other hand, no such conversion occurred when the air was kept dry; one sample was preserved in a wooden box for eight years without any deterioration taking place.

The determination of the nitrogen present as cyanamid and as dicyandiamid is considered at least as important as the determination of total nitrogen.

Effect of varying amounts of water upon the decomposition of crude calcium cyanamid and the formation of dicyandiamid, G. HAGER and J. KERN (*Ztschr. Angew. Chem.*, 29 (1916), pp. 221-223; *abs. in Jour. Soc. Chem. Indus.*, 35 (1916), No. 15, pp. 856, 857; *Chem. Abs.*, 10 (1916), No. 20, pp. 2608, 2609).—Quantities of crude calcium cyanamid of 100 gm. each were treated separately with 5, 10, 15, 25, and 50 gm. of water and inclosed in air-tight glass vessels. After five and seven months the material was analyzed. The fertilizer used

contained total nitrogen 18.62 per cent, of which 17.73 was water-soluble, cyanamid nitrogen 16.75 per cent, nitrogen as dicyandiamid 0.5 per cent, as ammonia 0.24 per cent, and as "urea" nitrogen (i. e., the element left in the filtrate after precipitation of the dicyandiamid) 0.48 per cent.

Seven months' storage without added water caused no perceptible change. With 5 and 10 gm. of water the changes were very small, the dicyandiamid nitrogen rising to 0.61 and 0.87 per cent, respectively. The presence of 15 gm. of water produced more change, the dicyandiamid nitrogen rising to 1.13 per cent and the urea nitrogen to 0.71 per cent. The cyanamid nitrogen fell to 13.61 per cent and the ammonia nitrogen to 0.14 per cent. Very little change took place in the first 10 days when 25 gm. of water was added, but after seven months 2.58 per cent of dicyandiamid was found. With 50 gm. of water profound changes took place and the material set to a hard stone-like mass. After two and one-half and seven months the dicyandiamid nitrogen rose to 7.51 and 9.17 per cent, respectively, the cyanamid nitrogen falling to 2.81 and 0.28 per cent, respectively, in the same periods. It is pointed out that calcium cyanamid should not be stored after it has become wet, but may be used immediately. The use of water to produce it in a granulated form is considered not likely to succeed.

The analyses were performed by Caro's method.

Calcium cyanamid, L. MALPEAUX (*Vie Agr. et Rurale*, 5 (1915), No. 2, pp. 28-30).—This is a review of experimental work by the author and others on the use of calcium cyanamid as a fertilizer, showing that when used under proper conditions it gives results comparable with those obtained with sodium nitrate and ammonium sulphate.

It is concluded that for the practical use of cyanamid it should be applied and incorporated in the soil at the time the soil is prepared for seeding. It should be used in the fall for winter cereals, avoiding spreading when mixing except on pasture. Mixtures of cyanamid with superphosphate should be avoided.

Two references to literature bearing on the subject are appended.

Phosphate fertilizers for Hawaiian soils, and their availability, W. T. McGEORGE (*Hawaii Sta. Bul.* 41 (1916), pp. 45, pls. 4).—Studies of the solubility of the phosphoric acid naturally occurring in certain Hawaiian soils, as well as of the behavior of various phosphates when applied to them, are reported.

Pot experiments with millet, cowpeas, buckwheat, radishes, and turnips on sandy volcanic soil, ferruginous red-clay soil, and a red soil with less clay, to determine the availability of different phosphates when applied in amounts equivalent to 0.007, 0.014, 0.021, and 0.028 per cent phosphoric acid, indicated that the soluble phosphates in frequent light applications are the most effective on Hawaiian soils, especially the red clays. Iron and aluminum phosphates were found to be readily available sources of phosphoric acid in Hawaiian soils, the former more so in the first crop in the absence of added lime. In sand cultures these phosphates surpassed clay and rock phosphate.

"In most locations it is poor economy to add bone meal or other difficultly soluble phosphates to Hawaiian soils. . . . In wet districts (uplands) phosphate rock, bone meal, basic slag, or reverted phosphate should be very effective, more especially so if applied to highly organic soils or used in systems of diversified agriculture where they may be incorporated with green manure crops." Basic slag was more effective as a source of phosphoric acid than phosphate rock, bone meal, or reverted phosphate. Lime applied with phosphates temporarily assisted the plants in assimilating phosphoric acid, but it soon lost its effectiveness unless present in excessive amounts.

Studies of the solubility of phosphoric acid in potted soil, of phosphates after addition to soil, and of phosphoric acid occurring naturally in Hawaiian soils, as indicated by treatment with several reagents, indicated that "hydrochloric acid of official strength does not dissolve all of the phosphoric acid of Hawaiian soils. To determine the total phosphate content, it is necessary to fuse the soil with sodium carbonate. Fifth-normal nitric acid has very little solvent action upon the phosphate in the soils, indicating the absence of appreciable quantities of calcium phosphate. One per cent citric acid has a much stronger solvent action than fifth-normal nitric acid. Of the weaker solvents, 1 per cent sodium hydroxid is the strongest, due to its action on the iron and aluminum phosphates. The fertilizer (phosphate) requirement of the soil is not measured by solubility in water or fifth-normal nitric acid, but it may be indicated by the solubility in citric acid. The solubility of a phosphate before it is added to a soil can not be used as a criterion of its solubility after addition, but it may indicate its availability. The fixation of a soluble phosphate by the soil may be influenced by the basicity of the soil. Availability as determined with solvents does not agree in full with that indicated by plant growth."

A description of a modification of the official method used in determining the phosphoric-acid content of Hawaiian soils by reason of the high titanium content is appended. See also a previous note (E. S. R., 35, p. 503).

**Phosphate fertilizers**, B. SUTHERLAND (*Proc. Roy. Soc. Victoria, n. ser.*, 28 (1916), No. 2, pp. 208-210).—Field experiments on 1/200-acre plats with early and late wheat and oats are reported. The purpose was to compare sodium orthophosphate, sodium pyrophosphate, and trimetaphosphate with each other and with superphosphate when used in amounts equivalent in phosphoric-acid content to 100 lbs. of superphosphate per acre.

It was found that metaphosphate gave in all cases a better crop than superphosphate, but with some plats the difference was practically negligible. Pyrophosphate was in every case less satisfactory than superphosphate. Metaphosphate applied as a top-dressing in spring did very little good. Apparently the value lay in the initial start to the very young plant. In the case of brown oats, which grew rapidly, the advantage of using metaphosphate was very marked.

**The citric acid solubility of the phosphate in Thomas slag**, P. KROLL (*Ztschr. Angew. Chem.*, 29 (1916), I, pp. 199, 200; *abs. in Jour. Chem. Soc. [London]*, 110 (1916), No. 645, II, p. 389; *Chem. Abs.*, 10 (1916), No. 20, p. 2608).—It was found that the addition of sand in the converter raised the citrate solubility of the phosphoric acid in Thomas slag on the average by about 1 per cent. The amount of soluble phosphate seemed to have a tendency to remain constant for each particular type of slag and to be more or less independent of the total amount of phosphate present. This constant was about 18.5 per cent for sand slag and 17.3 per cent for normal slag.

**The conservation of phosphate rock in the United States**, W. C. PHALEN (*Bul. Amer. Inst. Mining Engin.*, No. 119 (1916), pp. 1901-1934, figs. 6).—This report deals with the production, exportation, and conservation of phosphate rock in the United States, describes substitutes used therefor, and describes domestic and foreign deposits, especially those of Florida and Tennessee and of Africa and the southern Pacific Ocean.

**The salt and alkali industry**, G. MARTIN, S. SMITH, and F. MILSOM (*London: Crosby Lockwood & Son, 1916, pp. VIII+100, pl. 1, figs. 36*).—In addition to chapters on the manufacture of common salt, hydrochloric acid, sodium sulphate, and sodium carbonate, two chapters are included on the Stassfurt salt industry and on potassium salts in general.

"Loog as;" or the ash of the alkali bush, A. STEAD (*So. African Jour. Sci.*, 12 (1916), No. 11, pp. 540-542).—Analyses of the ash of *Mesembrianthemum junceum* showed a content of water soluble potash of 22.2 per cent or potassium carbonate 32.59 per cent. This plant, it is stated, grows luxuriantly in many of the Karoo districts of South Africa. It is considered an excellent source of potash for acid soils and is estimated to be of about twice the normal manurial value of kainit.

Chemical analysis of ash (*Alaska Stas. Rpt. 1915*, p. 25).—An analysis by E. FULMER of one sample of volcanic ash showed a potash content of 2.48, calcium oxid 3.8, and total phosphoric acid 0.36 per cent.

Outline of the relation of the use of lime to the improvement of the soil, E. O. FIPPIN (*N. Y. State Col. Agr., Cornell Univ. Ext. Bul. 5* (1916), pp. 16, figs. 2).—This is a popular discussion of soil acidity and its causes, the tolerance of different crops for acidity and alkalinity in soils, and different kinds of lime and their use and benefits in acid soils with special reference to New York conditions.

It is stated that "in the hill sections of New York from southern Wyoming, Ontario, and Madison counties southward, and throughout the Hudson valley region with the exception of a few small areas, . . . the lack of lime is one of the most important limiting factors in larger crop production. In the remaining cultivated sections of the State the use of some lime is generally beneficial. The part of the State where the soil is best supplied with lime is a strip of land extending southward for a distance of from 10 to 20 miles from a line passing through Utica, Syracuse, Rochester, and Niagara Falls."

Analyses of commercial fertilizers, fertilizer supplies, and home mixtures, C. S. CATHCART ET AL. (*New Jersey Stas. Bul. 297* (1916), pp. 3-43).—This bulletin contains the results of actual and guaranteed analyses of 635 samples of fertilizers and fertilizing materials collected for inspection in New Jersey during 1916.

### AGRICULTURAL BOTANY.

A textbook of botany for colleges, W. F. GANONG (*New York: The Macmillan Co., 1916*, pp. XI+401, figs. 276).—This book is designed as an introductory course in botany as part of a scheme in general education, and not for the preparation of professional botanists. In conformity with this idea, attention is given to the larger and more obvious aspects of plant activity, special emphasis being placed on the interpretation of principles and the connection of botanical science with knowledge in general and with man's relations to plants. As the author states, "the book may be described as an attempt to present and interpret the humanly important aspects of plant nature in the light of our modern scientific knowledge." It is intended to be used in conjunction with laboratory work to connect the facts there discovered with the science as a whole.

Some recent researches in plant physiology, W. R. G. ATKINS (*London: Whittaker & Co., 1916*, pp. XI+328, figs. 27).—The object of this book is to present to senior students and investigators the results of recent work in some of the branches of plant physiology which are attracting attention. Matter already current in textbooks has been almost entirely excluded. The choice of material by the author was influenced to a considerable degree by his work at the School of Botany, Trinity College, Dublin. The main subjects treated are carbohydrates, pectic substances, osmotic pressure, permeability of cells, functions of the wood, and oxidases. Extensive bibliographies of these different subjects are included in the publication.

The principles of plant teratology, W. C. WORSDELL (*London: Ray Soc., 1915, vol. 1, pp. XXIV+270, pls. 25, figs. 61*).—This book is designed to describe in a scientific manner abnormalities in the plant kingdom and to determine why the structures are present and how they came to be produced. The author considers the study of teratological data of importance in determining various morphological problems, and the work is offered as a contribution to the evolutionary origin of plant organs. The present volume treats of the teratology of fungi, bryophytes, etc., and of the root, stem, and leaves of higher plants. A volume dealing with the flower is contemplated.

Morphology of the flowers of *Zea mays*, P. WEATHERWAX (*Bul. Torrey Bot. Club, 43 (1916), No. 3, pp. 127-144, pls. 2, figs. 4*).—The author reports the result of a study carried on for about two years on the morphological characters of the flowers in six subspecies of *Z. mays*.

Maize is normally monœcious. Both male and female spikelets are two-flowered. The silk is structurally and functionally a stigma. Pollination is effected by gravity or wind. Though cross-pollination is more usually the method, self-pollination occurs to some extent. In flowers of either sex, the rudimentary organs of the opposite sex may be replaced by organs of normal appearance which are regularly functional in some varieties of corn.

Xerophotic movements in leaves, F. C. GATES (*Bot. Gaz., 61 (1916), No. 5, pp. 399-407, figs. 8; abs. in Science, n. ser., 43 (1916), No. 1106, pp. 360, 361*).—An account is given of observation and experimentation on xerophotic response as manifested in the upward turning or curling movements of leaf blades resulting from the drying effect produced through the agency of light, particularly direct sunlight. The lessened turgor of the cells of the upper side allows a movement in the direction from which the desiccating agency comes, the resulting position decreasing the amount of radiant energy received and thus reducing the harmful action of intense sunlight upon chlorophyll and transpiration.

In the localized type of xerophotic response, the difference in turgidity is confined to a limited area, such as the pulvini of the leaflets. In the more generalized type, the difference is between the upper and the lower part of the blade. The first type is said to have been noted in all species of legumes studied and to have been observed in some other families. The second type has been observed in the monocotyledonous families Poaceæ, Araceæ, Marantaceæ, and Zingiberaceæ. While in nature the response was produced by direct stimulation from the sun, it was produced also by the action of the chemical desiccating agents alcohol and xylol on *Gliricidia sepium* and *Ipomœa pes-capræ*. The amount of movement which took place under suitable conditions at any season varied with different conditions between 45 and 70° above the horizontal.

The daily movements of leguminous leaflets, F. C. GATES (*Plant World, 19 (1916), No. 2, pp. 42-45, figs. 2*).—In giving a daily program of the movements of leguminous leaflets under the influence of direct sunlight, as above noted, two classes may be considered. One, exemplified by *Gliricidia sepium*, is that of plants with a drooping night position. The other, exemplified by *Leucœna glauca*, is that in which the night position is above instead of below the horizontal. The changes during 24 hours are discussed, with mention of a certain amount of irregularity observable about the time of the full moon.

The warm water treatment of the seeds of certain herbaceous and green manure plants that are difficult to germinate, J. A. HONING (*Meded. Deli-Proefstat. Medan, 10 (1916), No. 1, pp. 16-23*).—The results are given of some experiments in the germination of Albizzia, Mimosa, Pithecolobium, and *Crotalaria* seeds previously immersed in warm water at different temperatures and for different lengths of time.

The best germination of *Albizzia* seed was secured when the seed was soaked for at least three hours in water at a temperature of about 60° C. *Mimosa* seed gave the best results when soaked in water of from 60 to 70°, and *Pithecolobium* seed when the temperature of the water was from 70 to 75°. Soaking in warm water was disadvantageous to *Crotalaria* seed and soaking in cold water was not of much advantage.

The physiology and technique of forcing growth in woody plants, F. LA MARCA (*Staz. Sper. Agr. Ital.* 48 (1915), No. 10-11, pp. 772-782).—Tests as detailed with various woody plants in regard to the effects of removing bud scales, puncturing the bud with a fine needle, injecting water or compounds of copper, iron, nickel, etc., have led to the conclusion that the forcing effects observed are due almost wholly to the disturbance consequent upon wounding or to the consequent release from pressure in the bud.

Injury to vegetation resulting from climatic conditions, G. E. STONE (*Jour. N. Y. Bot. Gard.*, 17 (1916), No. 202, pp. 173-179; *U. S. Mo. Weather Rev.*, 44 (1916), No. 10, pp. 569, 570).—The general conditions which result in winter injury to plants are briefly stated, and more complete accounts are given of the character and causes of frost cracks, sun scald, sun scorch, and bronzing.

The formation of parenchyma wood following winter injury to the cambium, A. J. MIX (*Phytopathology*, 6 (1916), No. 3, pp. 279-283, figs. 3).—The author describes the formation of parenchyma following winter injury to apple trees.

Effect of sodium salts in water cultures on the absorption of plant food by wheat seedlings, J. F. BREAZEALE (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 9, pp. 407-416, figs. 8).—The results are given of experiments undertaken to determine the extent to which the presence of the various sodium salts commonly found in alkali soils affects the absorption of plant food elements by wheat seedlings. Sodium chlorid, sulphate, and carbonate, in concentrations ranging from 50 to 1,000 parts per million, were employed in connection with a standard nutrient solution, and wheat plants grown on floating disks were used to test the effects of the different salts.

All of the sodium salts tested, when added to the nutrient solutions, even in the highest concentrations mentioned, did not measurably affect the nitrogen absorbed from the culture solutions, but sodium chlorid decreased the absorption of potash slightly, though it did not affect that of phosphoric acid. Sodium sulphate in concentrations of 1,000 parts per million depressed the absorption of potash and phosphoric acid to approximately 70 per cent of that of the control cultures. Sodium carbonate in the same concentration reduced the absorption of potash to 20 per cent of the control and that of phosphoric acid to 30 per cent. The depressing effect of sodium carbonate was also observed in concentrations as low as 100 parts per million.

The relative effect of sodium sulphate and sodium chlorid in depressing the absorption of potash is said to be directionally the same as the relative hydrolysis resulting from the reaction of the two salts with the calcium carbonate present in the culture solution. This is believed to suggest that the observed effects in the case of sodium sulphate and sodium chlorid may be due in part to the accumulative action of the slight amounts of sodium carbonate formed in this reaction.

Assimilation of iron by rice from certain nutrient solutions, P. L. GILE and J. O. CARRERO (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 12, pp. 503-528).—The results are given of a series of investigations carried on at the Porto Rico Experiment Station to determine whether the reaction of soils has any effect on the assimilation of iron by rice. Rice was grown in acid, neutral,

and alkaline solutions with different forms and quantities of iron and the effect of the reaction of the solution on the assimilation of iron was noted.

When judged by the growth of plants, ferrous sulphate, ferric citrate, and ferric tartrate afforded sufficient iron when used in proper quantities in acid and neutral solutions. Ferric chlorid proved an inferior source of iron and dialyzed iron utterly inadequate. Ferric tartrate was the only form of iron which furnished sufficient amounts of that element for the nutrition of plants in alkaline solutions.

Plants grown in acid solutions contained the highest percentages of iron. Those grown in neutral solutions contained higher percentages of iron than those grown in alkaline solutions when some forms of iron were used, but they contained equal percentages when other forms were used. The percentages of nitrogen, phosphoric acid, lime, magnesia, and carbon-free ash in plants grown in six different solutions did not vary appreciably when compared with the iron content.

It appears that rice was not found to be particularly sensitive to the reaction of the solution except as the reaction influenced the availability of the iron. This is believed to substantiate previous work in showing that lime-induced chlorosis is caused by a lack of iron and in indicating that the only acton of carbonate of lime in inducing chlorosis lies in its diminishing the availability of iron.

The influence of manganese on plants, G. MASONI (*Staz. Sper. Agr. Ital.*, 48 (1915), No. 10-11, pp. 322-338; *abs. in Chem. Abs.*, 10 (1916), No. 19, p. 2495; *Internat. Inst. Agr. [Rome]*, *Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 3, pp. 345, 346).—Reporting a further study (E. S. R., 26, p. 226) of maize as affected by manganese compounds, the author states that manganese in very small or larger proportions has shown some favorable influence on the growth of plants, but that this influence is not specific or direct.

The nutrition of green plants by means of organic substances, C. RAVENNA (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 25 (1916), I, No. 9, pp. 649-655, figs. 3).—The author, describing experiments carried out with sterile cultures of maize in aqueous solutions of glucose, states that the leaves produced starch even in the absence of carbon dioxid but only in the light, the portion of the solar spectrum most influential in this regard being that showing the greatest activity in regard to chlorophyll. The plants rooted in sugar solution but deprived of carbon dioxid and of oxygen did not form starch even in sunlight.

The cause of the disappearance of cumarin, vanillin, pyridin, and quinolin in the soil, W. J. ROBBINS (*Science, n. ser.*, 44 (1916), No. 1147, pp. 894, 895).—A preliminary report is given of a biological study made to determine the reason for the disappearance of the toxic activity of cumarin, vanillin, pyridin, and quinolin in soils.

Flasks containing soils to which the above compounds had been added were inoculated with infusions from normal soils and incubated for two months, after which wheat was planted in the soils. The growth of the wheat plants in the inoculated soil showed that the toxic properties of the compounds had largely disappeared, while their effect was still very evident in bottles containing sterile soil. This is believed to indicate that the disappearance of the compounds is due to biological causes. From the bottles or pots, three species of bacteria were isolated, one of which was found to use pyridin as a source of nitrogen, while one used vanillin and another cumarin as a source of carbon. No organism has yet been found to act on quinolin.

As a result of the author's investigations, it is considered that the enormous increase in the number of organisms in the treated pots and the disappearance

of the four substances in the soils depend on the fact that the compounds serve as sources of food for different species of bacteria.

**Studies in permeability.**—III, **The absorption of acids by plant tissue**, MILDEED HIND (*Ann. Bot. [London]*, 30 (1916), No. 118, pp. 223-238, figs. 11).—This is a continuation of the series of studies begun by Stiles and Jørgensen (*E. S. R.*, 35, p. 224). The present author has attempted to ascertain how far the rapid absorption of hydrogen ions, as previously noted in regard to hydrochloric acid in aqueous solution, is characteristic of acids in general. Several acids were used in this work, which was carried out with potato tubers and with living plants of *Vicia faba*. The part played by proteins was also studied.

It was found that the hydrogen ions of all the acids examined are rapidly absorbed by plant tissue from dilute solutions. The anion largely determines the effect of the acid on the cell, the fatty acids contrasting strongly with the mineral acids in this respect. Proteins may also influence acid absorption by plants. Lecithin was not shown to be concerned in such absorption.

**Production of root hairs in water**, ETHEL M. BARDELL (*Univ. Wash. Pubs. Bot.*, 1 (1915), No. 1, pp. 9).—The author, outlining experimental work on root hair development in water in the case of sunflower, maize, pea, bean, wheat, oats, and *Tradescantia*, states that elongation of root cells is greater in air than in water. The number of root hairs tends to decrease with increase of strength of the fractional solutions of normal potassium nitrate, this being ascribed to a decrease of absorption and consequent diminution of turgor.

The conclusions of SNOW (*E. S. R.*, 17, p. 849) have been confirmed by the employment of other methods. It is stated that light conditions do not affect root hair production. Curves and swellings favor the production of root hairs, which are more abundant on the concave side of curves. Usually cortical cells in hairy portions are shorter than those in hairless portions, also the average length of hairy cells grown in air, water, or fractional solutions of normal potassium nitrate is usually less than that of hairless epidermal cells and of cortical cells.

**A method for maintaining a constant volume of nutrient solutions**, O. L. CLARK (*Science, n. ser.*, 44 (1916), No. 1146, pp. 868, 869, fig. 1).—A method for the automatic renewal of nutrient solutions is briefly described.

**Proposed classification of the genus Rollinia, with descriptions of several new species**, W. E. SAFFORD (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 12, pp. 370-384, figs. 3).—In an attempt to correct what are considered errors of classification, the author has made a revision of available material which is considered to belong to the genus *Rollinia*, from which certain forms have been previously set apart by him under the generic name *Rolliniopsis* (*E. S. R.*, 36, p. 220).

**Desmopsis, a new genus of Annonaceæ**, W. E. SAFFORD (*Bul. Torrey Bot. Club*, 43 (1916), No. 4, pp. 183-193, pls. 3, fig. 1).—Technical descriptions are given of species to which the new generic name *Desmopsis* is given, under the specific names *D. panamensis*, *D. galeottiana*, *D. mazonii*, *D. bibracteata*, and *D. oerstedii*.

**Pleiospermium, a new genus related to Citrus, from India, Ceylon, and Java**, W. T. SWINGLE (*Jour. Wash. Acad. Sci.*, 6 (1916), No. 13, pp. 426-431).—A new genus, *Pleiospermium*, is described to include the species formerly known as *Limonia alata* and *L. dubia*. These species, which are technically described, are suggested as suitable stocks for Citrus, the former on the drier soils, the latter on limestone hills. It is thought that, on account of its primitive and polymorphic nature, *P. dubium* may hybridize with some true citrus species.

The origin of new varieties of *Nephrolepis* by orthogenetic saltation.—I. Progressive variations, R. C. BENEDICT (*Bul. Torrey Bot. Club*, 43 (1916), No. 5, pp. 207-234, pls. 6).—This is a study of the varying progeny of the so-called Boston fern, *N. exaltata bostoniensis*, known to have produced in about 15 years at least 60 horticultural forms which have been named. The great majority at least have originated as bud sports. Most of the descendants have tended away from the original variety, some back toward it, but few, if any, reaching the original form or the form of the immediate parent.

The variations, which are produced and preserved in large numbers, partly owing to the extensive production and care of the plant, are classified as progressive and regressive or reversive in regard to the parent form, the variation coefficient of the former being very low as compared with that of the latter. The variations are all discrete or discontinuous, the differences paralleling those existing among many wild species of ferns and of flowering plants, except that the horticultural forms do not possess adaptability to natural conditions, decreased vigor of growth usually characterizing departure from type. The origins or causes of variation have not been rendered apparent, but they appear to proceed as if from internal stimulation under conditions apparently serving, not as causes but as means of preserving the variants.

The mutual influence of genotypical factors, TINE TAMMES (*Rec. Trav. Bot. Néerland.*, 13 (1916), No. 1, pp. 44-62).—Reporting the results of further investigations (E. S. R., 34, p. 629) on *Linum usitatissimum* carried through several generations, the author states that the plants not only possess factors apparently independent of each other, but that in many cases the visible manifestation of a factor depends upon the presence or absence of several other factors. Probably no factor is entirely independent of other factors. The relations of certain factors in case of flax varieties are discussed.

Dry grassland of a high mountain park in northern Colorado, F. RAMALEY (*Plant World*, 19 (1916), No. 9, pp. 249-270, figs. 6).—Results of an ecological study of a dry grassland park in northern Colorado at an elevation of about 9,000 ft. are given. The vegetation is described as low growing, consisting largely of grasses and sedges, with many profusely flowering perennials. Five seasonal periods are recognized, and a series of six societies is noted, corresponding to historical stages from bare soil to the ultimate grassland of the park. The effect of climate, soil, and evaporation and the importance of rodents, etc., are briefly discussed.

Fungus flora of Texas soils, F. C. WERKENTHIN (*Phytopathology*, 6 (1916), No. 3, pp. 241-253, fig. 1).—A report is given of an investigation in which a study was made of the fungi in three kinds of soil, one of which was from a cotton field, another from a greenhouse, and the third from the university campus, where the soil had not been disturbed for at least 20 years. The frequency and distribution of the fungi are indicated.

The author states that to a depth of 4 in. the fungi were fairly uniformly distributed, while below 4 in. no viable fungus spores were found. No marked variation in species of fungi was observed that could be attributed to cultivated or virgin soil. The climate is believed to have a great influence on the flora of soils, species of *Aspergillus* being the dominant soil fungi of the South. Species of *Penicillium* frequently found in northern soils are said to be rare in Texas soils, and the *Mucors* are not so abundant in southern soils. Pathogenic fungi, especially species of *Fusarium*, were found to live in the soil as saprophytes throughout the winter.

Relative importance of fungi and bacteria in soil, H. J. CONN (*Science*, n. ser., 44 (1916), No. 1146, pp. 857, 858).—The author reports having tested several soils by Waksman's method (E. S. R., 35, p. 820), using, however, only

about 10 mg. of soil in an attempt to find whether fungi are as important as bacteria in soil.

While bacteria were found abundantly, mold hyphae were present only where the soil contained considerable organic matter. Where organic matter was not added to the soil development was slow, and this is considered to suggest that molds are relatively insignificant in the soil. In the author's experiments nearly every kind of soil micro-organism except molds was found, and it is thought doubtful whether fungus mycelium is present to any significant extent in soil.

### FIELD CROPS.

**Report of [field crops] work at Fairbanks Station, J. W. NEAL (*Alaska Stas. Rpt. 1915, pp. 42-50, 52-54, pls. 4*).—This reports the continuation of field crop work previously noted (E. S. R., 33, p. 631).**

The frost-free period at this station extended over an interval of 109 days, spring seeding being begun 18 days earlier than in 1914. Four varieties of spring wheat were tested, with the Russian variety known as H. G. giving the most promise for the future. Marquis proved to be of good quality and the Russian spring wheat No. 36 was early in maturing. Three varieties of spring barley were tested, with hull-less barley No. 19851 from the station 1914 crop giving the best results. This barley has never failed to mature a full crop when seeded reasonably early. Sixty-day, Canadian, and Finnish Black oats were tested, with the latter giving the highest yields. All varieties gave heavy yields, but Finnish Black did not yield so heavily as heretofore. Gesselberg spring rye was tested but was slow in maturing.

Twelve varieties of winter wheat and four of winter rye were seeded in the fall of 1914. Eight of the wheat varieties winterkilled, while the four remaining varieties wintered a fair stand, but were killed by the spring freezing and thawing. This is the first experience of the kind at the station. All the rye wintered a fair stand, but were badly damaged by the spring freezing and thawing. These experiments have been continued and in the fall of 1915 each plat was covered with a heavy well-matted growth.

All alfalfa varieties except a few plants of the Siberian strains winterkilled. Notes are given on the following varieties that made a fair growth: North Swedish, Hansen Chernob, Hansen Cossack, and Hansen Semipalatinsk. New seedings were made of Grimm alfalfa No. 162, Pioneer Strain, Disco No. 28, and Grimm Coin Holder (Glenheim strain). These varieties all made a heavy top growth and the early plants produced many well-filled seed pods. Later seedings were made of Orenburg common alfalfa, hardy Grimm, and Glenheim White Blossom. No seed pods were set. In these seedings the seed was sown in deep furrows and lightly covered and packed to aid early germination.

Red clover winterkilled, but a considerable quantity of seed practically matured from the spring seeding, although the weather was too wet to cure the crop.

One hundred and fifty bu. of Petrowski turnips were set out in the spring, but owing to drought only 260 lbs. of seed were saved.

Fifteen potato varieties were tested and the yields listed in tabular form. Considerable loss has been sustained from the corky scab and potato rust which the formaldehyde treatment did not seem to check.

**Report of [field crops] work at Kodiak Live Stock and Breeding Station, M. S. SNODGRASS (*Alaska Stas. Rpt. 1915, pp. 71-76, 76-79, pls. 2*).—The continuation of field crop work previously noted (E. S. R., 33, p. 632) is reported for 1915.**

The winter of 1914-15 is reported as being an open one, permitting early plowing and seeding. The plowing at Kodiak was sufficiently deep to mix thoroughly the soil and volcanic ash, resulting in a friable sandy loam which warms up quickly in the spring. At Kalsin Bay it was impossible to plow to sufficient depth to obtain a proper mixture. The work of restoring vegetation on the deep volcanic ash was also continued by seeding 23 acres of mixed grass with the oats seeded for hay.

Cow kale was grown with good success at Kodiak. Brief notes are also given on oats for hay and silage, barley, rutabagas, turnips, and mangels. The four best potato varieties produced in 1914 were again tested. Burpee Superior and Clark Alaska Seedling gave the highest yield, but Irish Cobbler and Extra Early Ohio were more uniform and superior in quality.

About 135 tons of silage was secured at Kalsin Bay composed of mixed bluetop, fireweed, and beach grass. At Kodiak 18 tons of oats and 16 tons of beach grass were put up as silage.

Report of [field crops] work at Rampart Station, G. W. GASSER (*Alaska Stas. Rpt. 1915, pp. 54-67, 68, 69, pls. 6*).—Field crops work previously noted (E. S. R., 33, p. 632) is continued for 1915.

Meteorological data are submitted for the last 10 years at the Rampart Station. The frost-free period for 1915 was 107 days, and the winter of 1914-15 is reported as exceptionally mild.

Notes are given on the clearing and preparation of new land and on the production of grain hay. The 1-acre field of brome grass seeded in 1910 continues to give a perfect stand although the crop was very light in 1915.

Of the 20 varieties of alfalfa tested 4 have survived as perfectly hardy. These 4 are yellow-flowered and are *Medicago falcata*, Omsk, Obb, and Gobi Desert. Grimm, Sand Lucern, Mongolian, and Chernob alfalfas, all purple flowered, were considerably winterkilled. In the Grimm plat a number of plants showing marked variation from the standard were observed and the seed gathered separately for further testing. Special attention is being given to yellow-flowered varieties of alfalfa, and particularly *M. falcata*. About 2,000 plants of this variety were transplanted in the spring and set 30 in. apart each way. Abundant growth resulted, together with considerable seed production. The coarse-stalked plants seemed to bear more seed than the fine-stalked ones, and a number of such plants were marked and the seed kept separate. A small plat of Omsk alfalfa has ripened considerable seed, but Gobi Desert and Obb, although as hardy as Omsk, have never ripened seed and, furthermore, are of procumbent growth. *Trifolium lupinaster* is conspicuous for its hardiness, producing stalks about 16 in. long and always ripening its seed, but as a hay crop it is a failure. *Vicia cracca* produced a good growth after coming through the winter in excellent shape. A yellow-flowered vetch was found in this plat and the seed gathered separately.

Hybridization work was continued with winter rye, barley, and spring wheat. Kharkov winter wheat was crossed with Sandomirka, an earlier Russian variety which apparently possesses great hardiness. Of the new hybrids grown for the first time only one or two of each give any promise for the future, but all will be seeded again so that single-head selections can be made from the second generation. Single-head selection is being rigidly adhered to.

In addition to the hybrids, 12 varieties of spring wheat were grown. Chogot, Irkutsk, No. 306, hybrid 24 A 1, hybrid 24 A 2, and H. G. ripened 100 per cent seed by August 20. Certain of these varieties possesses objectionable features, but their earliness renders them valuable for hybridization. The Sandomirka winter wheat wintered 95 per cent, the Kharkov next at 20 per cent.

Three varieties of spring rye were tested, with Irkutsk maturing the earliest of the three. None was so early as the earliest winter rye, nor were the heads so well filled. Ten varieties of winter rye were tested, and all were hardly provided they were protected by a covering of snow, but there was a difference of 12 days in the ripening. Irkutsk, Giant French, Amber, No. 959, Monster, and Station No. 195 all ripened by August 12.

A number of oat varieties are being tested, with Finnish Black, Norwegian, and South Dakota No. 637 ripening the earliest (95 days). Hybrids of Copperfield and Toholampi have come true and were a day earlier than the above-named varieties.

Pamir barley ripened earliest, in 79 days. Three new varieties were tested.

Notes are also given on variety tests with buckwheat, flax, and broad beans, and cultural notes on hemp.

Twenty-nine new potato varieties from the Sitka Station were tested for the first time. Tests were also made to determine the value of seed pieces cut to a single eye, but contradictory results were obtained.

[Field crop] notes at Sitka Station, J. P. ANDERSON (*Alaska Stas. Rpt. 1915, pp. 32, 33, fig. 1*).—Seventy-seven varieties of potatoes tested at the Sitka Station are listed, giving the yields for 1914 and 1915. Owing to the dying of the tops of some early varieties in August and the differences in the fertility of the soil, results for the two years are not comparable. The quality is reported as good in all but a few varieties. Four additional varieties were grown for the first time in 1915.

Results of experiments, 1915, A. E. V. RICHARDSON (*Jour. Dept. Agr. Victoria, 14 (1916), Nos. 3, pp. 147-152; 5, pp. 288-295, figs. 5*).—In rotation tests, the most profitable increases were obtained in a rotation of wheat and hay with forage crops, such as peas and barley, thus eliminating fallowing.

In fertilizer tests the best results were obtained from the use of 1 cwt. of acid phosphate per acre. Lime and nitrogenous fertilizers have not been profitable. High yields were obtained from all manurial treatments. Manure with acid phosphate gave the highest yields.

Wheat sown at the rate of 60 lbs. per acre the first week in May gave the best results, and Yandilla King and Dart Imperial proved to be the highest yielding wheat varieties. In green manuring tests wheat gave higher yields after fallowing than after green manure crops, either when the latter were plowed under or fed off to sheep.

Pasture crops in the prairie provinces, T. J. HARRISON and J. BRACKEN (*Agr. Gaz. Canada, 3 (1916), No. 5, pp. 419-430, figs. 8*).—Pasture conditions in the provinces of Manitoba and Saskatchewan are discussed in some detail. Various mixtures of grasses and other forage crops are recommended for perennial, biennial, or annual pastures for each section.

Germination experiments with grasses and legumes, A. BURGERSTEIN, (*Ztschr. Landw. Versuchsw. Österr., 18 (1915), No. 8-9, pp. 559-570*).—The results of studies to determine the relative growth values of different grasses and legumes, when the seeds are planted at different depths, are discussed, and work of a similar nature conducted as pot and field experiments by the author is described.

In the pot experiments maize seeds, as determined by the depth of planting from which the coleoptile reached the surface of the soil, showed the greatest vigor of growth, being followed in decreasing order by oats, barley, wheat, and rye. Among the leguminous seeds studied peas and lentils showed a marked vigor of growth, as in a loose, humus, or sandy soil, at a seed depth of 40 cm. (about 15.6 in.), 40 per cent of the peas and 50 per cent of the lentils were capable of reaching the soil surface.

Striking differences in vigor of growth were exhibited by seeds of *Phaseolus multiflorus* and *P. vulgaris*. Planted at a depth of 20 cm., 97 per cent of the seed of *P. multiflorus* and only 12 per cent of the seed of *P. vulgaris* produced plants. When planted at a depth of 25 cm., 88 per cent of the seed of *P. multiflorus* reached the surface of the soil, while not a single seedling of *P. vulgaris* appeared.

Sprouting seeds of *Helianthus* and *Cucurbita* showed less vigor in pushing through the soil than those of peas, lentils, vetch, and *P. multiflorus*. Thickly planted seeds of *Zea* maize and *P. vulgaris*, at depths of from 15 to 25 cm., came up quicker and in greater numbers than the same number of seeds planted on twice the area. In humus soil the difference in the vigor of growth of seeds of *Vicia sativa* was insignificant, in sandy soil plainly perceptible, and in clay soil quite marked. Lentil seeds, which possess a relatively high vigor of growth, exhibited practically no difference when planted 25 cm. deep.

In the field tests with seeds planted at depths of 15, 20, and 25 cm., the percentage of successful germination and growth was as follows: Lentils, 53, 42, and 16; peas, 50, 44, and 20; *V. faba*, 68, 40, and 20; *P. multiflorus*, 36, 8, and 0; and *P. vulgaris*, 2, 0, and 0, respectively. In a similar test, with the depth of planting at 10 cm., the percentage of seedlings secured from the seeds planted was as follows: Pumpkin, 40; sunflower, 66; oats, 82; barley, 75; and club wheat, 60 per cent.

Crucifers and grasses, with reference to their utilization of soil nitrogen, T. PFEIFFER, W. SIMMERMACHER, and MISS M. SPANGENBERG (*Fühling's Landw. Ztg.*, 64 (1915), No. 21-22, pp. 521-534).—This article, somewhat controversial in nature, reports the results of several series of pot experiments conducted to determine (1) whether the plant food contained in mustard grown in a mixture with grain can be utilized by the grain crop after the mustard has been destroyed by spraying with iron sulphate solution, (2) whether the yield of oats grown alone is as large as or larger than the yield of oats grown mixed with mustard which is destroyed when it begins to bloom, and (3) whether the nitrifying capacity of the soil is changed under the influence of a mixed culture of oats and mustard as compared with oats grown alone. The conclusion drawn from the results secured is that mustard is without effect in each of the relationships studied, and that the assumption of L. Hiltner regarding the value of mustard in mixed culture in relation to the companion crop is not based on adequate evidence.

Grasses with creeping roots.—Advantages and disadvantages, E. BREAKWELL (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 12, pp. 1031-1034, pls. 7).—This article deals with a discussion of the root systems of Johnson grass (*Sorghum halepense*), couch grass (*Cynodon dactylon*), Rhodes grass (*Chloris gayana*), summer grass (*Panicum sanguinale*), and *Paspalum dilatatum*, a common pasture grass in New South Wales. The advantages of each grass as a pasture grass due to its stoloniferous tendencies and physiological characteristics are discussed and illustrated. The disadvantages when the grasses are encountered in cultivated fields are also discussed, and methods of eradication for each grass are briefly outlined.

[The production of young grass with heavy applications of sulphate of ammonia], H. NEUBAUER, G. HILLKOWITZ, and P. SCHNEIDER (*Fühling's Landw. Ztg.*, 64 (1915), No. 21-22, pp. 534-543).—Experimental data are presented showing the greater production of total and digestible protein from a given area of either high or medium fertility when the grass was cut every 14 days as compared with cutting three times during the season. In connection with the use of 400 kg. of ammonium sulphate per hectare (356 lbs. per acre), it was observed that an increase in grass production took place immediately

after the application, and that this effect had almost entirely disappeared at the end of four weeks. Notes are also given on the cost of fertilizing grass lands, the feeding value of young grass, the artificial curing of grass, and the production of forage on lawns and in parks.

[Chlorin requirement of the buckwheat plant], T. PFEIFFER and W. SIMMER-MACHER (*Landw. Vers. Stat.*, 88 (1916), No. 1-2, pp. 105-120).—This article reviews work on this subject by a number of investigators and describes a study made by the authors to determine the relation of chlorin to the growth of the buckwheat plant. In view of the results secured it is concluded that while chlorin is a necessary plant food, the chlorin requirement of the buckwheat plant is very small and that the presence in the soil of relatively large quantities of chlorin compounds affects its growth injuriously.

Corn growing under droughty conditions, C. P. HARTLEY and L. L. ZOOK (*U. S. Dept. Agr., Farmers' Bul.* 773 (1916), pp. 24, figs. 15).—This publication deals with corn growing in dry-land regions, although the principles discussed apply wherever corn is produced.

It is pointed out that while corn is not naturally adapted to semiarid regions owing to its heat requirements and peculiar flowering habits, it has been introduced into dry-land agriculture because of its extensive production in other regions and the advantages it presents in rotation with the small grains. The chief essentials of corn growing are given as water, heat, soil fertility, and seed, any one of which may, if lacking, become the limiting factor to production. In the semiarid regions the limiting factor is for the most part either water or heat, and the discussion is based, therefore, on the best means of getting moisture into the soil and retaining it there until the corn crop can make the most efficient use of it. The following points are discussed in some detail from the standpoint of dry-land farming: Preparation of the seed bed, time of planting, methods of planting, and cultivation.

Corn growing under irrigation is briefly discussed, and some of the causes for failures in this practice pointed out. The short growing seasons and extreme differences between day and night temperatures are given as limiting factors encountered, although they may be partly overcome by growing early maturing adapted varieties. Some of the preventable causes for failure are given as overirrigation, too frequent irrigations, too early irrigations, and too little cultivation.

Certain animal and insect enemies of the corn crop are briefly mentioned, together with general control measures. The necessity for good seed and the choice of adapted varieties are discussed.

The practice of pasturing corn to hogs is recommended for semiarid regions, not only because of the labor saved in harvesting the crop but also because the flint and flour varieties may thus be grown.

Some factors influencing yield in maize, H. WENHOLZ (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 12, pp. 1023-1029).—This article deals in a popular way with the meteorological conditions under which maize is produced in New South Wales. The time and method of planting are noted, together with the selection of adapted varieties and good seed. The preservation of seed between seasons is discussed in some detail.

Hulled oats, P. O. OVERGAARD (*Tidsskr. Planteavl*, 23 (1916), No. 1, pp. 84-102, fig. 1).—The results of experiments on the seed value of hulled oats showed that oats hulled in the process of threshing and sown mixed with normal oats are worthless for seeding purposes when soil conditions are unfavorable for germination or when the seed is subject to insect attacks. Under favorable conditions hulled oats in a mixture gave up to 50 per cent of the production of

normal oats. When sown alone and the rate of seeding increased in proportion to the lower germination, as compared with oats in normal condition, hulled oats gave a full yield. Careful hulling by hand did not reduce the seed value, but clipping the oats seemed to be an additional factor in reducing the percentage of germination of the hulled portion of the grain.

Oats from a poorly developed crop and injured in thrashing to the extent of having the hull removed wholly or in part produced in a mixture with normal seed grain only 19 per cent of the yield of the normal seed. A well-developed crop of oats grown on clay soil contained about four times as many hulled kernels as a crop of lower quality produced on sandy soil, other conditions being equal. Running the thresher at a moderate speed appreciably reduced the quantity of hulled kernels in the grain. Examination of the seed samples showed in most cases not over 2 per cent of hulled kernels, and it is thought that as a rule not more than this proportion will be found when the oats have been thrashed with a good machine properly adjusted and operated.

Potato experimental fields, 1915-16, J. T. RAMSAY (*Jour. Dept. Agr. Victoria, 14 (1916), No. 2, pp. 107-115, figs. 5*).—This article gives detailed plans of potato experiments being conducted in Victoria. Diagrams are submitted showing the arrangement and treatment of the various plats.

Sweet potato curing in Texas, E. W. COLE (*Texas Dept. Agr. Bul. 49 [1916], pp. 25, figs. 10*).—This is a popular publication on the production and curing of sweet potatoes in Texas. Detailed information is given for the propagation, cultivation, and harvesting of the crop. Two methods of storing the product are discussed—(1) the old-fashioned pit or hill method, and (2) the specially designed storage house. The construction of the latter is described in some detail, and the cost of curing sweet potatoes by this method is estimated at 68.1 cts. per bushel.

Relationship between the average wheat yield and the winter rainfall, A. E. V. RICHARDSON (*Jour. Dept. Agr. Victoria, 14 (1916), No. 1, pp. 37-40, fig. 1*).—This article is based on observations of the relationship between the average yields of wheat and the composite average rainfall over the wheat belt from May to October for the past 25 years. Ten centers, representative of the wheat districts, were chosen in which observations were made. The past 24 seasons were divided into two 12-year periods, each having approximately the same composite average rainfall, namely, 9.5 in. for the first period and 9.8 in. for the second period. The results obtained are illustrated by means of a graph and are discussed in some detail.

In a comparison of the yields with the rainfall it is shown that for every inch of winter rainfall 0.77 bu. of wheat was secured per acre in the first period and 1.12 bu. per acre in the second period. This indicates a gain of 46 per cent brought about by improved methods of cultivation. The effect of abnormal seasons on wheat production is discussed. It is pointed out that the wheat crop of Victoria may be estimated in November from a knowledge of the winter rainfall in the typical wheat districts.

Experiments with the manuring of wheat, F. COLEMAN (*Jour. Dept. Agr. So. Aust., 19 (1916), No. 8, pp. 716-718*).—This is a report of experiments conducted for the past eleven years on the manuring of wheat. Increased yields and values of manured plats over unmanured plats for the 11-year period are given in tabular form.

Researches on wheat selection.—I, Does the value of a wheat grain depend on its position in the ear? A. E. V. RICHARDSON and W. H. GREEN (*Jour. Dept. Agr. Victoria, 14 (1916), No. 3, pp. 140-146, figs. 4*).—This article reports experiments with wheat conducted at the Rutherglen Experiment Station, Victoria. In order to eliminate environmental influences as far as possible, a

modification of the system of centgener plats suggested by Hays (E. S. R., 13, p. 165) was adopted. The investigations were conducted with the Federation variety of wheat. Forty-three ears of wheat were examined and the kernels removed and weighed and their position in the ear marked. In addition, these weighed and marked kernels were planted, and their location carefully marked to test the fertility and vigor of kernels at different positions in the ear and in the spikelet.

The results obtained indicated that the weight of individual grains increases from either extremity to the middle of the ear. The middle kernels of the spikelets are invariably less in weight and impoverished and, if they germinate, produce less prolific plants. As these grains are undersized and low in weight an efficient grading machine eliminates them. In mass selection for crop improvement the rejection of the upper and lower portions of the ear of wheat is deemed justifiable.

The cross-fertilization of wheats, W. J. SPAFFORD (*Jour. Dept. Agr. So. Aust.*, 19 (1915), No. 4, pp. 362-375, figs. 6; 19 (1916), No. 7, pp. 628-633).—This article is a detailed discussion of the principles involved and the methods used in the cross-fertilization of wheats.

Wheat breeding in New South Wales, J. T. PRIDHAM (*Agr. Gaz. N. S. Wales*, 26 (1915), Nos. 7, pp. 563-567; 8, pp. 645-650; 9, pp. 737-741; 12, pp. 1013-1017).—This article consists chiefly of the assembling and discussion of the underlying principles of plant breeding as formulated by Mendel, De Vries, Johannsen, and others, and supplemented by breeding investigations with wheat in New South Wales. The American Breeders' Association Yearbook for 1907 is quoted at some length.

Notes on some recently imported wheats, F. B. GUTHRIE and G. W. NORRIS (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 12, pp. 1018-1022).—The results of milling and baking tests applied to Russo-Barletta, White Walla, Red Walla, Blue Stem, and Baril, all imported Argentine wheats, are reported. Russo-Barletta and Baril appear to be the most satisfactory milling wheats. An unnamed variety of wheat imported from Japan and Red Fife from Oregon were also tested.

Seed wheat.—Varieties for distribution among farmers, A. E. V. RICHARDSON (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 2, pp. 65-78, figs. 9).—This article deals with the methods employed by the Victoria department of agriculture in developing varieties of wheat for distribution among farmers. The value of seed selection and grading is pointed out. All varieties are started on 1/10-acre "stud" plats from which seed is selected for 1-acre "seed" plats, which in turn furnish seed for 10-acre "bulk" plats. More or less detailed notes are given on 16 varieties that have been developed, including information as to yielding qualities, cultural characteristics, disease resistance, etc.

Cost of production of field crops, H. C. WILSON and A. J. WHELAN (*Jour. Dept. Agr. Victoria*, 14 (1916), No. 5, pp. 296-307, figs. 4).—An itemized statement of the cost of harvesting wheat in Victoria is given. Three operations are compared, namely, harvesting 12 acres for hay, harvesting 309 acres with a binder for threshing, and stripping and winnowing 24 acres.

Improved apparatus for determining the test weight of grain, with a standard method of making the test, E. G. BOERNER (*U. S. Dept. Agr. Bul.* 472 (1916), pp. 15, figs. 8).—This bulletin describes an apparatus for accurately determining the test weight of grain, especially designed for use in grain standardization work. The common practices met with in commercial grading are compared and their imperfections pointed out. A standard method for making all such tests is urged, and specifications submitted for that purpose.

Rules and regulations of the Secretary of Agriculture under the United States Grain Standards Act of August 11, 1916, D. F. HOUSTON (*U. S. Dept. Agr., Office Sec. Circ. 70 (1916), pp. 54*).—This circular contains the rules and regulations of the Secretary of Agriculture pertaining to the United States Grain Standards Act of August 11, 1916. The text of the act (E. S. R., 35, p. 308) is included.

Clover and grass seed inspected in 1914, C. P. SMITH (*Maryland Sta. Bul. 197 (1916), pp. 58*).—Seed inspections of red clover, crimson clover, sweet clovers, alfalfa, alsike and white clovers, hairy vetch, timothy, millets, and orchard grass for 1914 are reported.

A table of tolerance for purity variations is given and an explanation made of its calculation and use.

Anatomical determination of the seeds of *Cuscuta trifolii* and *C. suaveolens*, J. BEENATSKY (*Landw. Vers. Stat., 88 (1916), No. 1-2, pp. 1-11, figs. 7*).—The results are reported of an anatomical study of the seeds of two species of dodder, conducted to determine the cause of the so-called limy or calcareous condition of some seeds, and to discover a method for the recognition of the species of such seeds in doubtful cases.

It is stated that the limy seeds show no indication of parasitism, but that they are seeds which, having failed of fertilization, dry up in the condition or stage of development reached before the time of fertilization arrives. The anatomical differences determined were as follows: In limy seeds of *C. trifolii* the proportion of the thickness to the length was as 1:1.4, and in those of *C. suaveolens* as from about 1:1.6-1:1.9. The palisade cells in the limy seeds of *C. trifolii* were from 6 to 8  $\mu$  in the first row, about 8  $\mu$  in the second, and only near the hilum perceptibly more than 8  $\mu$  in length, as compared with from 8 to 16  $\mu$  in the first row and 10 to 30  $\mu$  and over in the second row in similar seeds of *C. suaveolens*. The starch grains of the limy seeds did not prove of value for a systematic classification.

A new weed, G. QUINN and H. W. ANDREW (*Jour. Dept. Agr. So. Aust., 19 (1915), No. 4, pp. 380-383, figs. 3*).—The appearance of the cruciferous weed *Carrichtera annua* is reported in a limited area of South Australia. A botanical description of the plant is given.

Some points in fan weed control (*Montana Sta. Circ. 12, Sup. (1915), pp. 4*).—This circular supplements a publication previously noted (E. S. R., 28, p. 46), dealing with fan weed (*Thlaspi arvense*), its introduction into new territory, and its control.

## HORTICULTURE.

[Horticultural investigations in Alaska], C. C. GEORGESON, J. P. ANDERSON ET AL. (*Alaska Stas. Rpt. 1915, pp. 8-13, 15, 22, 29-32, 33-39, 50-52, 67, 68, 76, pls. 5*).—The horticultural work at the Sitka Station and at the branch stations was continued along lines previously noted (E. S. R., 33, p. 637).

The numerous crosses between cultivated strawberries and the wild species of Alaska have yielded many plants of sufficient merit to be retained for further test and experiment. Some of these hybrids with the coast species as one of the parents have been found to be hardy at both Rampart and Fairbanks stations, but hybrids that have the interior species for one of their parents are expected to be better adapted for that region than are those now under test. The raspberry-salmonberry crosses made several years ago (E. S. R., 28, p. 435) have yielded plants of no value, and this breeding work has been discontinued. Some hybrids between the raspberry and the thimbleberry (*Rubus parviflorus*) and between a native crab apple and early summer apples fruiting at the Sitka

Station have been secured and are under observation. Selection and breeding studies are also being conducted with gooseberries, cranberries, blueberries, and huckleberries.

The season of 1915 was favorable for fruit production in the station's test orchard and a number of early-maturing apples fruited. The tests thus far made have shown that only the early-maturing apples are adapted to Alaska. Of these Yellow Transparent and the Livland Raspberry are the only two that can be recommended at this time. Of the cherries, only sour cherries have proved of any value as orchard trees, and in most seasons even sour varieties are more or less a failure. Thus far, other orchard fruits have not been successful.

The usual variety tests with vegetables are reported, and data are given on the adaptability of various ornamental trees, shrubs, perennials, and annuals to conditions at the stations.

Notes on some garden plants cultivated in the experimental garden of the Portici Royal Agricultural High School, F. DE ROSA (*Atti R. Ist. Incoragg. Napoli*, 6. ser., 67 (1915), pp. 251-272).—This comprises notes on the condition and character of different classes and varieties of vegetables grown in the school garden.

Two winter salads, endive and Witloof, L. BUSSARD (*Vie Agr. et Rurale*, 6 (1916), No. 46, pp. 354-356, figs. 3).—The methods employed in forcing endive and Witloof chicory during the winter months are described.

Modern fruit marketing, B. S. BROWN (*New York: Orange Judd Co., 1916*, pp. XIX+283, figs. 136).—In the present treatise the practices of harvesting, packing, storing, transporting, and selling of fruit are considered in detail.

The Christ-Junge taxation method; general rules for the application of the method for all horticultural plants (*Maandbl. Nederland. Pomol. Ver.*, 6 (1916), Nos. 4, pp. 73-80; 7, pp. 148-163; 8, pp. 166-174; 9, pp. 194-202).—This article discusses in detail a method of taxing fruit trees which have not come into bearing, those which are yielding normal crops, and those which have passed their prime. The method here considered was advanced by Dr. Christ and E. Junge in their guide for the determination of the worth and rental value of fruit industries.<sup>1</sup>

The cost of producing apples in Wenatchee Valley, Washington, G. H. MILLER and S. M. THOMSON (*U. S. Dept. Agr. Bul.* 446 (1917), pp. 35, pls. 4, figs. 7).—This comprises a detailed study made in 1914 of the current cost factors involved in the maintenance of orchards and the handling of the crop on 87 orchards.

The average investment per farm surveyed was \$20,974; the average investment per acre of bearing apples alone was \$1,925. The equipment investment was \$444 per farm, or \$47 per acre, exclusive of stock. There was an average of two horses per farm, or 5.3 tillable acres per horse. The orchards studied averaged 6.5 acres and 81 trees per acre, and the trees averaged 11 years of age.

The total annual cost of production was \$469.73 per acre, or 79.2 cts. per box, f. o. b. Of this, labor cost constituted \$179.09 per acre, or 30.2 cts. per box, and cash cost, including interest on investment, \$290.64 per acre, or 49 cts. per box. This was the annual cost for the average orchard under clean cultural management, and where under alfalfa or clover management, this cost was reduced about 2 cts. per box. The yield per acre on the bearing orchards from which data were secured was 593 boxes, or 7.3 boxes per tree. This represents all yields on trees from 7 to 11 years, inclusive.

<sup>1</sup> Anleitung für die Wert und Rentabilitätsberechnung der Obstkulturen auf neuer Grundlage. (Berlin: P. Parey, 1913, 2. rev. and enl. ed., pp. VIII + 175.)

The ten leading varieties in the bearing orchards were Winesap, Jonathan, Esopus, Rome Beauty, Stayman, Gano, Ben Davis, Yellow Newton, Arkansas (Mammoth Black Twig), and Arkansas Black. In orchards of from one to five years of age varieties such as Delicious, Winter Pearmain, and Banana are replacing varieties like Ben Davis, Arkansas, and Arkansas Black.

The general cost of establishing a meadow orchard of cider apples, A. TRUELLE (*Vie Agr. et Rurale*, 6 (1916), No. 48, pp. 391-396, figs. 5).—A discussion with estimates of cost entering into the establishment of a cider orchard in land used for pasture.

Methods and problems in pear and apple breeding, W. R. BALLARD (*Maryland Sta. Bul.* 196 (1916), pp. 79-92, figs. 3).—Investigations in the improvement of orchard fruits have been conducted by various investigators at the station for 11 years. The data secured from these breeding projects are reserved for a later publication. The present bulletin is limited to a discussion of some of the methods which have been found useful and some of the problems which have been encountered in these investigations. The phases discussed include knowledge of varieties, the blooming period, collecting and ripening pollen, emasculation, pollination, bagging and labeling, setting of the fruit, gathering and planting the seed, handling the seedlings, early elimination of undesirable types, the permanent planting, and the fruiting age. A summary is given of the pear and apple crosses made at the station showing the number of buds pollinated and the number and percentage of fruit set.

Pear breeding, W. R. BALLARD (*Jour. Heredity*, 7 (1916), No. 10, pp. 435-442, figs. 4).—This comprises a reprint of the greater part of the above noted bulletin.

Growing cherries east of the Rocky Mountains, H. P. GOULD (*U. S. Dept. Agr., Farmers' Bul.* 776 (1916), pp. 36, figs. 29).—A treatise on cherry culture discussing the extent and distribution of cherry growing, locations and sites for cherry orchards, methods of propagation, selection of stocks and trees, the season for planting trees, care of trees when received from the nursery, preparation of the land, planting operations, pruning at time of planting, tillage and maintenance of soil fertility, intercrops, irrigation, pruning, fungus diseases and insects and other pests, picking and handling the fruit, varieties, the sterility of sweet cherries, the sequence of ripening of different varieties, and the future planting of cherries.

Self-sterility in dewberries and blackberries, L. R. DETJEN (*North Carolina Sta. Tech. Bul.* 11 (1916), pp. 5-37, figs. 9).—This bulletin presents in detail the results of an investigation of the extent and causes of sterility among varieties of dewberries and blackberries and their hybrid forms.

In the work with blackberries, which was conducted through three successive seasons, the 11 true blackberry varieties included in the study proved to be self-fertile, one hybrid blackberry was partially self-sterile, and three hybrids were self-sterile. In case of the dewberries, on the other hand, 10 of the true dewberries were self-sterile and three of the hybrid dewberries were self-fertile, thus indicating that sterility apparently occurs only in dewberries and their hybrids with blackberries. Examination of the origin of the different varieties of dewberries tested showed that all of the varieties that are pure lineal descendants of *Rubus trivialis* and those varieties in which *trivialis* blood predominates are self-sterile, while those varieties that come from *R. villosus* are generally self-fertile. Among the factors studied and discarded as not explaining the general sterility among dewberries are the structure of the flower, disease, daily blooming period of varieties, amount of pollen produced by the flower, environment, sterility due to hybridism, and the percentage of defective pollen grains produced. The author concludes that the self-sterility among

dewberries and hybrid varieties that are grown either as dewberries or as blackberries can be attributed either to a nonattraction or to a repulsion of the sexual elements from the same plant or from the same variety.

The pollen from most of the self-sterile varieties will successfully fertilize flowers of other self-sterile or self-fertile varieties. Fully self-fertile dewberry plants and blackberry plants when self-pollinated produce apparently as good fruits as when cross-pollinated. The results of the study as a whole indicate that by judicious and careful selection of varieties one or several varieties may be included in the fruit plantation with a reasonable certainty of a good setting of fruit. In the case of partially self-fertile varieties and all of the recognized self-sterile varieties of dewberries and blackberries a good pollenizer is absolutely necessary. Under ordinary conditions several varieties should be included in the plantation so as to secure the best possible results from cross-pollination.

**The sycamore fig in Egypt**, T. W. BROWN and F. G. WALSINGHAM (*Jour. Heredity*, 8 (1917), No. 1, pp. 3-12, figs. 7).—An account of the sycamore fig with reference to its history, botany, and practices employed by the natives in the culture and ripening of the fig.

**The best papaws** (*Jour. Heredity*, 8 (1917), No. 1, pp. 21-33, figs. 7).—This article describes a number of papaw fruits and trees reported in 1916 as the result of prizes offered by the American Genetic Association for photographs of the largest papaw trees and for the best papaw fruits.

**Cocos nucifera**, F. W. T. HUNGER (*Cocos nucifera. Amsterdam: Scheltema & Holkema, 1916, pp. XII+146, pls. 40, figs. 12*).—A handbook on the knowledge of the coconut palm in the Dutch East Indies, including detailed information relative to its history, botany, culture, and products.

**The cultivation of limes**, J. B. HARRISON, C. K. BANCROFT, and G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 8 (1915), No. 4, pp. 135-142; 9 (1915), No. 1, pp. 4-10; 9 (1916), No. 3, pp. 122-129; 10 (1916), No. 1, pp. 6-8).—A popular treatise on lime culture, with special reference to British Guiana. In addition to cultural details information is given relative to the control of insect pests and diseases, cost of establishing a lime plantation, and preparation of lime products.

**The vanilla plantations of Tahiti and Moorea**, E. P. MEINECKE (*Les Vanillières de Tahiti & de Moorea. Papéiti: Govt., 1916, pp. 44*).—This embraces the results of a survey of the vanilla industry in the islands of Tahiti and Moorea. Information is given relative to the nature and extent of the industry; the various pests of vanilla, together with suggestions for their control; and the improvement of cultural methods.

**Germination of yerba**, V. GARIN (*Bol. Min. Agr. [Argentina]*, 20 (1916), No. 7-8, pp. 568-577, fig. 1).—The results are given of some germination tests of yerba maté seeds previously treated in different ways mechanically, chemically, and by stratification.

**Yerba maté (*Ilex paraguayensis*)**, G. T. BERTONI (*Bol. Min. Agr. [Argentina]*, 20 (1916), No. 7-8, pp. 578-592).—A paper similar to the above dealing with different methods of treating yerba maté seed preliminary to planting.

**The American nut industry**, H. A. GOSSARD (*Ohio Forester*, 8 (1916), No. 3, pp. 29-33).—A review of the American nut industry in its various phases, based largely on the literature of the subject.

**Effects of large applications of commercial fertilizers on carnations**, G. D. BEAL and F. W. MUNCIE (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 12, pp. 2784-2804).—This paper presents the data secured in a study of the causes and effects of overfeeding with the more ordinarily used commercial fertilizers. The fertilizers chosen for the experiment were dried blood, sodium nitrate, am-

monium sulphate, acid phosphate, disodium phosphate, and potassium sulphate. For comparison, sodium chlorid and sodium sulphate also were used on some sections. The work was conducted during the period 1912 to 1915. The more practical results relative to the injurious and beneficial effects of specific fertilizers have also been published in a previous paper (E. S. R., 32, p. 746). The additional data here given deal with alterations in plant activities and constituents due to the fertilizers. A bibliography of related literature is appended.

Determinations of dry weight and ash made from the foliage of the carnation plants showed an increase in both values with increased applications of fertilizers. An increased content of the fertilizing salts was detected in the plants after large applications of them to the soil. The total nitrogen determinations made upon plants in different stages of injury showed an increased intake of nitrogen when ammonium sulphate was applied, but an acquired tolerance by the plants when successive small applications were made. Injury from ammonium sulphate was not in proportion to the total nitrogen content.

Osmotic pressure determinations made upon the cell sap proved that with each fertilizer used the degree of injury varied with the osmotic pressure, but that not the same degree of injury was caused by different fertilizers at the same osmotic pressure. Injury is not a result of increased osmotic pressure exclusively. The increase in the osmotic pressure in a series of plants on soil receiving increasing applications of commercial fertilizers was accompanied by an increase in the total solids and ash of the sap and in the amount of the fertilizer taken up by the plant.

The total acidity of the sap of plants fed with ammonium sulphate, disodium phosphate, and monocalcium phosphate increased as indicated by phenolphthalein. The relation between the increase in total acidity and in the phosphorus content of the sap when the plants were fed with disodium phosphate proved that the phosphorus was taken in the form of dihydrogen phosphate, due not entirely at least to absorption of the base by the soil, but to the selective action of the plant as well.

Applications of potassium sulphate had no effect upon the acidity of the sap, but large applications gave a higher total sugar content in the sap from the stems of the plants as well as in the foliage. The starch content of the foliage of such plants was lower. These data indicate a more rapid hydrolysis of the starch in the foliage in the presence of an excess of potassium sulphate. The increased exudation of nectar observed in the flowers of these plants probably resulted from this increase in sugar content.

The history and botanical relationships of the modern rose, E. H. and F. A. WILSON (*Boston: Authors, 1916, blueprint*).—This consists of a chart prepared with the view of showing the progress in the evolution of the modern rose.

Some suggestions for improvement of the home grounds, W. H. SILL (*Pan Handle [W. Va.] Agr. Club Circ. 3 (1916), pp. 25, figs. 5*).—A popular treatise on the questions arising in the improvement and development of the home surroundings applicable to the small city lot, the suburban estate, and the farm.

## FORESTRY.

Handbook for rangers and woodsmen, J. L. B. TAYLOR (*New York: John Wiley & Sons, Inc., 1917, pp. IX+420, figs. 243*).—The object of this handbook is to serve as a guide for inexperienced men in woods work. Although the author has had primarily in mind the problems which confront a forest ranger in government, state, or private employ, it is believed that the suggestions offered may be of use to others whose work or recreation takes them into rough

and unsettled regions. The subject matter is discussed under the general headings of equipment, construction work, general field work, live stock, and miscellaneous. Numerous tables and miscellaneous information, together with a glossary of local and technical terms used of value to the forester, are appended.

**Ecological investigations upon the germination and early growth of forest trees,** R. H. BOERKER (*Thesis, Univ. Neb., 1916, pp. 90, pls. 5, figs. 23; Univ. [Neb.] Studies, 16 (1916), No. 1-2, pp. 1-89, pls. 5, figs. 23*).—A doctorate thesis to the faculty of the graduate college of the University of Nebraska, and constituting an inquiry into the effect of the more important habitat and seed factors upon the germination and early development of certain American forest trees for the purpose of obtaining data that may be used in the silvicultural management of these species. The author's observations were made on control cultures in the greenhouse. The results are presented in tabular form and fully discussed. A bibliography is appended.

**The significance of certain variations in the anatomical structure of wood,** R. P. PRICHARD and I. W. BAILEY (*Forestry Quart., 14 (1916), No. 4, pp. 662-670, fig. 1*).—This paper summarizes the results of one of a series of investigations that have been undertaken at the Bussey Institution in the study of plant tissues and cells, their comparative structure, relative conservatism, and behavior under the influences of various modifying factors. The present investigation deals with the variation in size of the principal woody elements (fibers and vessel segments) in various parts of the stem of the common shagbark hickory (*Carya ovata*).

**Relationship of the Douglas fir to lime in soil,** SOMEVILLE (*Quart. Jour. Forestry, 11 (1917), No. 1, pp. 1-6*).—An inspection of some Douglas fir plantations occurring in chalk lands led the author to conclude that, contrary to a rather common opinion, Douglas fir is more or less tolerant of lime, and may be recommended for planting even where solid chalk occurs within 2 ft. of the surface and where abundant lumps of chalk are met with even at a less depth.

**The girth increment of Hevea brasiliensis,** T. PETCH (*Ann. Roy. Bot. Gard. Peradeniya, 6 (1916), No. 2, pp. 77-86, pls. 5*).—In January, 1912, regular girth measurements on *H. brasiliensis* were begun at Peradeniya as part of an investigation into certain phases of the physiology of the tree. Tabular data are given showing the girth increases for 16 trees up to March, 1914, together with growth curves of untapped and tapped trees.

**Sugar pine,** L. T. LARSEN and T. D. WOODBURY (*U. S. Dept. Agr. Bul. 426 (1916), pp. 40, pls. 10*).—An account of the sugar pine (*Pinus lambertiana*) with reference to its importance, geographical and commercial range, botanical characteristics, growth, silvical requirements, reproduction, and forest types. Consideration is also given to the mechanical and physical properties of the wood, methods of logging and milling, values and grades of lumber, markets, uses, stumpage prices, growth and yield, and management, including the management of private timber lands. Appended to the bulletin are a volume table, based upon measurements of 910 felled trees taken by the Forest Service in California; a key for the identification of sugar pine, western white pine, and white pine woods; and a classification of sugar-pine lumber into grades.

**The forests of Worcester County,** H. O. COOK (*Boston: State, 1917, pp. 88, pls. 7, figs. 3*).—This comprises the results of a forest survey of the 59 towns in Worcester County, Mass., together with a study of their lumber industry. The data given for each town include the acreage in various forest types and age classes, the acreage in nonforest types, and the wood-using industries.

**Improving the woodlot,** J. B. BERRY (*Ga. State Col. Agr. Circ. 31 (1916), pp. 8, figs. 2*).—A popular treatise on woodlot management.

Scientific national forestry for New Zealand, D. E. HUTCHINS (*Jour. Agr. [New Zeal.]*, 13 (1916), Nos. 4, pp. 295-317, figs. 4; 5, pp. 375-396, figs. 4).—An account of the forests and forest conditions in New Zealand, with suggestions relative to the development of scientific forestry in the dominion. The subject matter is based upon the author's investigations on behalf of the government relative to the forests and forestry in New Zealand.

Annual return of statistics relating to forest administration in British India for the year 1914-15 (*Statis. Forest Admin. Brit. India, 1914-15*, pp. 25, pl. 1).—A statistical report relative to alterations in forest areas, progress of forest settlements, forest surveys, working plans, forest protection, planting operations, yields in major and minor forest products, revenues, expenditures, etc. Data are also given showing the revenue, expenditure, and surplus during the 25 years from 1890-91, together with a diagram showing the annual forest revenue, expenditure, and surplus for the 10 years, 1905-6 to 1914-15.

Snow injury to trees, G. B. RIGG (*Torreya*, 16 (1916), No. 12, pp. 257-260).—Observations on mechanical injury by snow to evergreen trees in the Puget Sound region during the winter of 1915-16 are given. The most striking fact observed was the large amount of injury to needle-leaf evergreens and the small amount of injury to broad-leaf evergreen trees and shrubs.

Forest fires in the United States in 1915, J. G. PETERS (*U. S. Dept. Agr., Office Sec. Circ. 69 (1917)*, pp. 6).—This circular presents the results of the first attempt to secure annual estimates of all forest fires in the United States. Thirty-seven States sent in returns which represent approximately 56 per cent of the forest area of the country. Tabular data are given showing the number and causes of fires reported in 1915, with the area burned over, and the amount of damage, and also an estimate for the territory from which no reports were received.

The actual losses on the 177,500,000 acres of Federal and private lands within the National Forest boundaries was \$353,389 and the estimated loss on all other forest lands in the United States is given as \$6,755,967. Within the National Forest boundaries 279,245 acres were burned over, as compared with an estimate of 5,627,405 acres on all other forest lands.

Forest insurance against fires in Finland, E. NYLANDER (*Skogsvårdsförs. Tidskr.*, 14 (1916), No. 8, pp. 625-628).—A short account of forest fire insurance in Finland, which was originated in 1914 and met with great success, a sum of 85,000,000 marks (\$16,405,000) being the immediate amount insured for.

Better apparatus for forest fire fighting, H. C. JOHNSON (*Canad. Forestry Jour.*, 13 (1917), No. 1, pp. 896-899, figs. 7).—Some successful results with a portable engine pump in fighting forest fires in Quebec are briefly discussed.

## DISEASES OF PLANTS.

Plant diseases, J. P. ANDERSON (*Alaska Stas. Rpt. 1915*, pp. 39-41).—Notes are given on the occurrence of diseases of a number of economic plants grown in the trial grounds of the Sitka Station.

Mycology, F. J. F. SHAW (*Ann. Rpt. Bd. Sci. Advice India, 1914-15*, pp. 104-109).—At Pusa it was found that although the ufra disease of rice can lie dormant in the soil and infect the young plants, cutting the diseased rice and burning it in place with a little kerosene oil prevented infection of the next crop. A rice disease at Balasore and at Bankipore could not be traced to any parasitic agent. Gwa-bo, which caused extensive damage in Burma, was investigated with no very definite result, *Sclerotium oryzae* appearing in about half the cases but probably not as a primary cause, and several insects as more probably causative in many cases.

Field experiments with tokra of tobacco have already yielded some results. *Orobánche cernua* and *O. indica* occur on tobacco, the latter being much more serious to solanaceous crops and the former causing more damage to crucifers. The effects of chemical manures on the influence of tokra are being tested.

Black thread of Hevea in Lower Burma, characterized externally by black lines in the tissue above the tapping cut and by failure of the tree to regenerate the bark over the tapped area, has not yet proved to be due to a fungus parasite but hyphæ of a *Phytophthora* have been found in adjacent bark.

A disease of sal (*Shorea robusta*) in the forests of the Duars was associated in every dead or dying tree with the presence of a rhizomorphic root fungus showing sporophores in advanced cases, and all showed a diseased condition of the phloem. The disease may prove to be due to a *Fomes*, the conditions for attack by which are not yet known.

*Rhizoctonia napi* was found to be a serious parasite of mustard and gram, though limited by its inability to grow actively at temperatures above 29° C. (80.3° F.). A fertile stage discovered is said to be identical with *Botrytis cinerea*. *R. destruens* causes a serious disease of betel vine and potato in Bengal, and it also occurs on suran, alfalfa, and peanut. This fungus may have a perfect stage in the genus *Corticium*. Experiments suggest that corrosive sublimate is more reliable as against *Rhizoctonia* than is either formalin or copper sulphate. Studies regarding the causation of blight of opium poppy render it probable that *Rhizoctonia* is seriously parasitic on this plant only under bad conditions, such as poor soil or defective drainage. *Peronospora arborescens* was abundant on poppy near Ghazpur.

Anthracnose of betel vine was investigated with slight results. Anthracnose of chillies caused much trouble in Burma.

Preliminary study of the soil floras of India showed a striking similarity of these with those of Europe. The red rot sugar cane fungus attacked juar under laboratory conditions. A banana rot was caused by a *Fusarium*, this disease appearing to be distinct from the Panama disease of bananas. The potato blight fungus is not able to survive in the heat of the plains. Results are to be published soon of a study of *Phytophthora* in Vinca. A disease of chillies proved to be of the type known as wilt. In Bihar the treatment of oat smut with formalin was, as usual, completely successful.

An account of plant disease work by departments is given in brief form, and this is followed by a short list of publications during 1914-15.

Nonparasitic stem lesions on seedlings, C. HARTLEY (*Abs. in Phytopathology*, 6 (1916), No. 3, pp. 308, 309).—Attention is called to a disease affecting the bases of the stems of young seedlings of conifers and various herbaceous plants, for which the name white spot is proposed. In many ways this disease resembles damping-off and is frequently confused with it, but it is considered that the disease is caused by high temperature at the soil surface, probably combined with the effects of light.

Life history and poisonous properties of *Claviceps paspali*, H. B. BROWN (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 9, pp. 401-406, pl. 1, figs. 2).—In continuation of previous work (E. S. R., 34, p. 676), the author gives the results of an investigation carried on at the Mississippi Experiment Station on the life history and poisonous properties of this ergot.

The fungus has been found quite abundantly in the vicinity of this station, at least 90 per cent of old heads of *Paspalum dilatatum* showing infection. Inoculation experiments have demonstrated the possibility of producing the disease. It has been observed that the sclerotia are readily found on the ground during the winter, where they remain until spring. In addition to the

ergot, two other fungi, *Fusarium heterosporum* and *Cladosporium* sp., are reported as infecting the heads of *P. dilatatum*. A brief account is given of experiments in feeding the sclerotia, as well as extracts made from the fungus, to guinea pigs, from which it appears that only the old sclerotia are poisonous and that they retain this property for at least 10 months.

Mowing pastures as often as the sclerotia become abundant is said to be an effective method of preventing poisoning, and this measure is of practical value in most places.

**Neocosmospora vasinfecta on potato and adzuki bean, F. A. WOLF** (*Phytopathology*, 6 (1916), No. 3, p. 301).—The author adds to the known host species of this fungus potatoes and adzuki beans, the organism found upon these plants agreeing morphologically with that recently described from peanuts (E. S. R., 32, p. 546).

**Pleosphaerulina on alfalfa, F. R. JONES** (*Phytopathology*, 6 (1916), No. 3, pp. 299, 300).—On account of a publication by Melchers (E. S. R., 33, p. 848) relating to a new alfalfa leaf spot in America, the author was led to contribute certain facts regarding the distribution, cultural habits, and taxonomy of the fungus, which has been observed in Madison, Wis., and Auburn, Ala., and has also been collected in Iowa, Minnesota, South Dakota, and Indiana.

**Dissemination of bur clover leaf spot, F. A. WOLF** (*Phytopathology*, 6 (1916), No. 3, p. 301).—The leaf spot of bur clover due to *Cercospora medicaginis* has been found to be spread by means of bur clover seed, and it is recommended that the seed be immersed for one minute in boiling water to prevent the occurrence of the disease. This treatment seems not only to destroy the fungus but also to hasten the germination of the bur clover seed.

**Experiments to control late blight of celery** (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 41 (1915), p. 17).—As a result of three years' experiments it is claimed that in seasons of normal rainfall losses from the late blight of celery can be prevented by spraying with a 4:4:40 Bordeaux mixture, beginning with the plants in the seed bed and continuing the spraying at intervals of ten days or two weeks throughout the growing season.

**The Rio Grande lettuce disease, C. W. CARPENTER** (*Phytopathology*, 6 (1916), No. 3, pp. 303-305, fig. 1).—A brief account is given of investigations of a lettuce disease occurring in the lower Rio Grande Valley, in which there is a reddening of the older leaves and blanching of the younger ones, restricted development of newly forming leaves accompanied by small, dark-colored blister spots along the border, and the development of numerous lateral adventitious shoots and dry and dead small roots. Analyses were made of the irrigation water used and of the soil about the affected plants, and it is believed that the trouble in question is due to the presence of alkali.

**A new smut on Sorghum halepense, I. B. P. EVANS** (*So. African Jour. Sci.*, 12 (1916), No. 11, pp. 543, 544, pl. 1).—A technical description is given of *Sorospodium simii* n. sp., which is said to attack Johnson grass in South Africa. Attention is called to this fungus and to the fact that it will probably attack Sudan grass unless precautions are taken against its introduction.

**Control of the sugar beet nematode, H. B. SHAW** (*U. S. Dept. Agr., Farmers' Bul.* 772 (1916), pp. 19, figs. 6).—A popular account is given of the sugar beet nematode (*Heterodera schachtii*), which, it is said, has been introduced into the United States and has become established in several sugar-beet districts of the West, where it causes considerable injury.

It is claimed that the only practical method of controlling the pest on a large scale is the rotation of crops not attacked by this nematode. Where small areas of land are infested, it is claimed that the nematodes may be eradicated by the liberal application of unslaked lime, which should be thoroughly

mixed with the infested soil. All forms of the nematode are said to be destroyed by short exposure to dry heat, the seed not being injured when exposed for ten minutes to temperatures of 149 to 158° F. This is suggested as a method for the control of the nematode if it should be established that it is introduced through the seed.

*Rhizoctonia* and *Sclerotium rolfsii* on sweet potatoes, L. L. HARTER (*Phytopathology*, 6 (1916), No. 3, pp. 305, 306).—The author reports the presence of *Rhizoctonia* on sweet potatoes, particularly in seed beds which have been too frequently watered, and of *S. rolfsii* on similar plants. The latter fungus is said to be quite destructive in Florida and Texas, sometimes completely destroying all plants in a hotbed.

A specific mosaic disease in *Nicotiana viscosum* distinct from the mosaic disease of tobacco, H. A. ALLARD (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 11, pp. 481-486, pls. 2).—The author reports having observed in the trial grounds at Arlington, Va., three plants of *N. viscosum* and a hybrid plant between that species and *N. tabacum* showing unmistakable symptoms of mosaic disease. This disease in its symptoms seems identical with the mosaic disease of tobacco, but the virus behaves very differently from that of tobacco mosaic disease in all inoculation tests. The author is of the opinion that this is a distinctive type of mosaic disease affecting *N. viscosum* and that in some manner it has originated from the ordinary form of mosaic disease.

During the same season, the author's attention was called to the typical symptoms of mosaic disease in peppers, which gradually spread over the whole field. Tomato plants in adjoining rows, however, were unaffected, and the expressed sap of the most severely affected pepper plants failed to produce the mosaic disease in young tobacco plants. Whether this disease was infectious to healthy pepper plants or was in some way related to the mosaic disease affecting *N. viscosum* was not determined.

Tomato blight, D. H. JONES (*Ann. Rpt. Ontario Veg. Growers' Assoc.*, 11 (1915), pp. 60-67, figs. 2).—An account is given of a disease of tomato which may cause heavy losses from plants grown under glass, but which has been found to only a very limited extent in the field. The trouble resembles in many respects the brown rot of solanaceous plants, but it has not been connected with attack by fungi, bacteria, or insects. It is thought to be due to some soil factor, possibly an injurious chemical reaction affecting the plant through the root system. Good results have been obtained in a limited number of cases from treating the soil with steam.

*Phytophthora infestans* on tomatoes, F. D. KERN and C. R. ORTON (*Phytopathology*, 6 (1916), No. 3, pp. 284-287, figs. 2).—A report is given of an unusual outbreak of *P. infestans* on tomatoes in Pennsylvania in 1915. The fungus appears to attack leaves, stems and fruit with about equal virulence, and there is believed to be some connection between weather conditions and the outbreak of the disease.

*Phomopsis mali* on young apple and pear trees in California, ELIZABETH H. SMITH (*Abs. in Phytopathology*, 6 (1916), No. 3, p. 309).—Attention is called to a disease of young apple and pear trees described by Roberts as due to *P. mali* (E. S. R., 28, p. 747). The trouble seems to be confined to one to three year old trees and is said to have been thus far of no great economic importance.

Observations on sour sap disease of apricots, EDITH H. PHILLIPS (*Abs. in Phytopathology*, 6 (1916), No. 3, p. 309).—Apricot trees are said to be affected with sour sap, or black heart, the first indication of the trouble being observed in the outer branches, which begin to die back, and in the wood in which brown

streaks are found. The disease appears during the summer and fall and is said to be particularly abundant in a wet year following one or two dry years.

Cultures have been made of soil protozoa, the material having been collected from diseased trees and from soil at the crown of apparently healthy trees. The protozoan fauna found in connection with the diseased trees was much more diverse and abundant than that from the sound ones.

A new leaf spot disease of cherries, B. A. RUDOLPH (*Abstr. in Phytopathology*, 6 (1916), No. 3, p. 308).—A leaf spot disease of sweet cherries is reported from a number of points in California and Oregon. The spots produced are rather large, brown, and usually definitely limited. The disease in most but not in all cases seems to originate in an insect mine. No fungus spores or fruiting bodies have been found in the spots occurring in nature, but tissue plantings on sterile media have repeatedly yielded a species of *Alternaria*. Comparisons made between this fungus and *A. citri* and also a species of *Alternaria* from watermelon leaves showed the three species to be very similar but to be distinguishable by certain reactions.

The action of copper sulphate on downy mildew, L. SEMICHON (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 37 (1916), No. 14, pp. 325-331; *Compt. Rend. Acad. Agr. France*, 2 (1916), No. 11, pp. 372-384).—The author reports results of experimentation and observations regarding the great variations noted in the duration of the efficacy of the reserve copper on the organs of grapevines, its mode of action, the conditions of its absorption, and the possibility of obtaining a greater and more certain efficacy in the copper employed.

After a period of desiccation, the proportion of soluble copper remaining available to oppose the fungus is found to be lowered in proportion to the subsequent precipitation. A short, light rain is much less disadvantageous in removing the available copper than a heavy and prolonged one. The proportion of reserve copper on the vines which may be redissolved as the result of precipitation decreases from day to day. The proportion of copper capable of being redissolved may be sufficient to kill or check spore germination, or it may be such as to favor spore development. The practical bearings of all these facts and of others noted are discussed, among these the action of the copper absorbed from the leaf surfaces or entering at points of injury during various developmental stages of the plant.

The action of copper salts against grape downy mildew, L. SEMICHON (*Rev. Vit.*, 44 (1916), Nos. 1134, pp. 224-230; 1136, pp. 255-261, figs. 2).—This is a somewhat more extended account of the studies reported above.

Some new strawberry fungi, F. L. STEVENS and A. PETERSON (*Phytopathology*, 6 (1916), No. 3, pp. 258-267, figs. 26).—In continuation of a preliminary note (*E. S. R.*, 33, p. 74) in which an account was given of some rots of strawberries, descriptions are given of *Sphaeronemella fragariae* n. sp. and *Patellina fragariae* n. sp. In addition to these species, other fungi were observed on berries in the field and market, and the authors claim that *Rhizopus nigricans* is the cause of most damage to shipped berries.

The diseases of bananas, J. E. VAN DER LAAT (*Bol. Agr. [São Paulo]*, 17, ser., No. 2 (1916), pp. 151-160, figs. 3).—This information has been noted from another source (*E. S. R.*, 31, p. 244).

*Sclerotium rolfsii* on Citrus, F. A. WOLF (*Phytopathology*, 6 (1916), No. 3, p. 302).—The author reports that during the past season this fungus caused the death of seedling grapefruit in a greenhouse in Auburn, Ala.

Cottony rot of lemons in California, C. O. SMITH (*Phytopathology*, 6 (1916), No. 3, pp. 268-278, figs. 5).—This is essentially an abridgement of the bulletin previously noted (*E. S. R.*, 34, p. 749).

A *Gloeosporium* disease of the almond probably new to America, HELEN L. CZARNECKI (*Abs. in Phytopathology*, 6 (1916), No. 3, p. 310).—An account is given of a disease of almonds which is considered identical with that occurring in Italy caused by *G. amygdalinum*.

The hard rot disease of gladiolus, L. M. MASSEY (*New York Cornell Sta. Bul.* 380 (1916), pp. 151–181, pls. 2, figs. 7; *abs. in Phytopathology*, 6 (1916), No. 1, p. 101).—The author describes a hard rot disease of gladiolus which is due to *Septoria gladioli*. The trouble affects both the leaves and the corms, causing considerable loss. The symptoms and etiology of the disease are described, together with the results of experiments on control. Soil treatments with chemicals are said to have given results of little practical value. The fungus has been found able to live over the winter on dead tops lying upon the ground, and it is suggested that these should be raked up in the fall and burned. It has also been found that the fungus lives for at least four years in the soil, and on this account crop rotation should be practiced for the elimination of the organism.

Red leaf spot of *Hippeastrum*, P. I. DOUGHERTY (*Abs. in Phytopathology*, 6 (1916), No. 3, p. 309).—In connection with the occurrence of conspicuous red spots on *Hippeastrum*, the author has isolated a fungus of a *Phyllosticta* type, and inoculations from single spore cultures have been successful in producing the disease.

Notes on oleander bacteriosis, C. O. SMITH (*Abs. in Phytopathology*, 6 (1916), No. 3, p. 308).—The bacteriosis of oleander is said to be occasionally found in California on nursery stock, the organism causing galls on the stems, leaves, and inflorescences. From studies thus far made, certain differences are said to have been recognized between the oleander organism and the two other gall-producing organisms, *Bacterium savastanoi* and *B. tumefaciens*. The oleander organism has given negative results in inoculations of plants susceptible to the crown gall organism, and the olive knot organism has also given negative results when inoculated upon the oleander.

Spraying experiments to prevent rose leaf blotch (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 41 (1915), p. 17).—As a result of experiments, it is claimed that the rose leaf blotch, due to *Actinonema rosea*, may be prevented by repeated spraying with lime sulphur beginning before the buds open in the spring and repeating at intervals of ten days throughout the growing season, except when the roses are in bloom. This treatment is said to be more efficient than Bordeaux mixture for the control of this trouble.

Forest botany, R. S. HOLE (*Ann. Rpt. Bd. Sci. Advice India*, 1914–15, pp. 98–103).—It is stated that the most important factors in the failure of sal (*Shorea robusta*) to reproduce itself may in the main be summed up as bad soil aeration and drought. Somewhat detailed discussion regarding these is given, with such remedial measures as a well aerated seed bed free from raw humus, full overhead illumination, and light side shade to prevent frost injury and retain moisture.

It is said that the spread of *Trametes pini* in stands of *Pinus excelsa* is effected chiefly by means of wind-borne spores entering through wounds in the stem, and that lopping should be prohibited.

A list is given of botanical and phytopathological publications.

Fungus diseases of trees, R. B. MAXWELL (*Amer. Forestry*, 22 (1916), No. 267, pp. 161–163, figs. 4).—Discussion of a general character is given of some fungus tree diseases, classed according to incidence on the leaves, on the stem and branches, and on roots, with suggestions in regard to their control.

A fertile witches' broom on larch, P. JACCARD (*Schweiz. Ztschr. Forstw.*, 66 (1915), No. 7–8, pp. 139–145, pl. 1).—Reporting observations on the character

and behavior of a large witches' broom of *Larix decidua* studied in Switzerland, the author states that his observations agreed with those of von Tubeuf (E. S. R., 24, p. 453), inasmuch as the characters of witches' broom may appear to be hereditary. He states that they are transmitted not only through the seeds, but also by means of grafts on normal trees.

*Peridermium harknessii* and *Cronartium quercuum*, E. P. MEINECKE (*Phytopathology*, 6 (1916), No. 3, pp. 225-240, figs. 2).—In continuation of a preliminary note (E. S. R., 34, p. 849), the author gives an account of investigations on the heteroecious stages of these species.

It is stated that, while not definitely proved, it is highly probable that *P. harknessii* is identical with *P. cerebrum*, and that in California *P. harknessii* and *C. quercuum* are to a high degree independent of each other. The heteroecism of *P. harknessii* on *Pinus radiata* is considered facultative, and it is believed highly probable that the same facultative heteroecism occurs in *P. contorta* and also in other hosts of *Peridermium harknessii*. *C. quercuum* winters over on *Quercus agrifolia*, new urediniospores forming in the spring around old, dead sori on old living leaves from which young leaves are infected. The heteroecism of the *Cronartium* is also considered facultative.

*Pinus resinosa*, a new host for *Peridermium acicolum*, R. G. PIERCE (*Phytopathology*, 6 (1916), No. 3, pp. 302, 303).—The author reports this rust as occurring on *P. resinosa*.

White pine blister rust (*Peridermium strobi*) (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 41 (1915), pp. 18-20).—A summary is given of the results of inspection of white-pine plantations and cultivated currants, from which it appears that the white-pine blister rust is quite widespread in Ontario and is established on native white pine, wild currants, and gooseberries.

[Disease in pine and chestnut], F. W. RANE (*Ann. Rpt. State Forester Mass.*, 12 (1915), pp. 50-52).—It is stated that the organism causing blister rust on white pine has been found on currants in the Housatonic Valley region, and it is feared that it may reach the pines.

Chestnut-bark disease is now to be found wherever chestnut grows in this section, the estimated proportion of trees attacked on a property at Mount Holyoke having risen from 5 per cent in September, 1912, to 90 per cent in November, 1915, and 75 per cent being in a dead or dying condition.

Spread of the chestnut blight in Pennsylvania, H. METCALF (*Phytopathology*, 6 (1916), No. 3, p. 302).—On account of the recent statements that the chestnut blight in Pennsylvania is coming to a standstill, the author presents a statement from the Deputy Commissioner of Forestry of Pennsylvania which indicates that the disease is continuing to spread rapidly in most localities.

Influence of Bordeaux mixture on the rates of transpiration from abscised leaves and from potted plants, W. H. MARTIN (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 12, pp. 529-548).—The author has carried on a series of experiments at the New Jersey Station to determine the influence of Bordeaux mixture on the rates of transpiration of abscised leaves of several species, as well as to determine the effect of this spray material upon the rates of water loss from potted plants of tomato, cabbage, pepper, eggplant, and soy bean.

The results of these experiments are held to substantiate the general principle already established by Duggar and Cooley (E. S. R., 31, p. 825) that the rates of transpiration from both abscised leaves and the leaves of potted plants are materially increased by an application of Bordeaux mixture. A surface covering of dry powdered copper sulphate was less effective in accelerating rates of transpiration than was a surface film of Bordeaux mixture, but was more effective than a film of barium sulphate. The acceleration of transpiration rates by Bordeaux mixture was more pronounced when the spray was applied

to the abscised leaves than when applied to the leaves of potted plants. The influence of Bordeaux mixture in increasing rates of water loss from abscised leaves became apparent immediately after the spray dried upon the leaves. The effectiveness of a film of Bordeaux mixture for inducing increased rates of water loss appeared to vary considerably in different plants in the case of abscised leaves and, to a lesser degree, in case of potted plants.

**Sulphur fungicides**, G. P. GRAY (*Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 160-174*).—This is a discussion, largely from a chemical standpoint, of the sources of the world's sulphur supply, the production, relative values, and employment of forms more or less adapted to use as fungicides, the employment of miscible sulphur and sulphur pastes, soluble homemade and commercial sulphur preparations, and the compatibility of sulphur with other fungicides.

### ECONOMIC ZOOLOGY—ENTOMOLOGY.

**Laws relating to fur-bearing animals, 1916**, D. E. LANTZ (*U. S. Dept. Agr., Farmers' Bul. 783 (1916), pp. 28*).—This is a summary of laws in the United States and Canada relating to trapping, protection, propagation, and bounties.

**Canaries: Their care and management**, A. WETMORE (*U. S. Dept. Agr., Farmers' Bul. 770 (1916), pp. 20, figs. 5*).—This publication has been prepared to meet requests received for information on the care of birds in sickness and in health.

**Shading effect of wire insect cages**, H. H. KIMBALL (*U. S. Mo. Weather Rev., 44 (1916, No. 9, pp. 501-506, figs. 3*).—Pyrheliometric measurements are reported which "show that at normal incidence with the wire cloth the wires intercept 0.332 of the solar radiation, or about what we would expect of 16-mesh cloth made of No. 29 wire, American gage."

**Relationship between the wetting power and efficiency of nicotin-sulphate and fish-oil-soap sprays**, L. B. SMITH (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 9, pp. 389-399, figs. 2*).—This is a report of investigations conducted at the Virginia Truck Experiment Station on 27 one-twentieth acre plats on which peas were sprayed five times and spinach and strawberries once with various mixtures of nicotin sulphate and fish-oil soap for the pea aphid, spinach aphid, and red spider, respectively. The wetting powers as well as the nicotin content of the solutions were determined.

The proportional efficiency of the sprays proved to be similar for each species. "When more than 4 lbs. of soap were used with 10 oz. of nicotin sulphate to 50 gal. of water, there was a loss of both wetting power and efficiency. When more than 8.75 oz. of nicotin sulphate were combined with 5 lbs. of fish-oil soap to 50 gal., a loss occurred in both the wetting power and the efficiency. When nicotin sulphate was used in quantities up to 10 oz. to a 1:50 fish-oil-soap solution none of the resultant sprays had an efficiency of more than 75 per cent. Also, when fish-oil soap was used alone in quantities not exceeding 8 lbs. to 50 gal., the highest efficiency of any of the formulas was only a fraction over 75 per cent. It was found that the nicotin content of the solutions remained the same irrespective of the amount of soap used.

"The loss of efficiency due to increasing the concentrations of the solutions is probably caused by a loss of both wetting power and insecticidal value of the soap. The loss of wetting power which occurs when the concentration of the solutions is increased has a stronger tendency to reduce the efficiency of the subsequent solutions if the original solution has an efficiency of 85 per cent or more than it does if the original efficiency is below 75 per cent.

"The actual importance of wetting power is difficult to determine in this case, as the fish-oil soap has insecticidal properties in itself. Where the wetting

power is affected it is probable that the soap is also broken down sufficiently to lose some of its value as an insecticide; hence, both factors must be considered as the cause of the loss of efficiency of some of the more concentrated mixtures."

Cyanid gas for the destruction of insects, with special reference to mosquitoes, fleas, body lice, and bedbugs, R. H. CREEL and F. M. FAGET (*Pub. Health Rpts. [U. S.], 31 (1916), No. 23, pp. 1464-1475*).—Following a review of the literature relating to the subject experiments with cyanid gas and sulphur dioxide are reported in tabular form.

"Cyanid gas is much cheaper than sulphur dioxide for mosquito destruction, costing only one-seventh as much as the latter gas, aside from requiring a much less duration of exposure. . . . For destroying bedbugs, roaches, and body lice sulphur is a cheaper fumigant than cyanid, but the latter possesses obvious advantages in lessened duration of exposure and noninjurious effect on fabrics, furnishings, merchandise, etc."

Some effects of freezing arsenate of lead pastes, R. A. DUTCHER (*Jour. Econ. Ent., 9 (1916), No. 6, pp. 561-566, pls. 3*).—The author finds that the settling properties of some commercial samples of lead arsenate paste are affected by freezing while others are not, that the microscopical appearances of all lead arsenate pastes examined were altered, and that the adhesive properties of lead arsenate pastes may be affected by freezing.

Forty-sixth annual report of the Entomological Society of Ontario, 1915 (*Ann. Rpt. Ent. Soc. Ontario, 46 (1915), pp. 232, figs. 65*).—This report includes the following papers:

Insects of the Season in Ontario (pp. 29-33) and The Imported Willow and Poplar Borer or Curculio (*Cryptorhynchus lapathi*) (pp. 33-40), by L. Caesar; Side Injury and Codling Moth, by E. P. Felt (pp. 40-43); The Home of *Gortyna stramentosa*, by A. F. Winn (pp. 43-48); Insects of Ste. Anne's, Quebec, Season of 1915 (pp. 48-50) and The Occurrence of *Tychius picirostris* on Clover at Ste. Anne's, Quebec (pp. 50-52), by E. M. DuPorte; Observations upon Some of the Predacious and Parasitic Hymenoptera, by Fyles (pp. 52-60); The Leaf-weevil (*Polydrusus impressifrons*) in New York, by P. J. Parrott and H. Glasgow (pp. 60-65); The Green Apple Bug (*Lygus invitus*) in Nova Scotia, by W. H. Brittain (pp. 65-78), noted on page 457; A Capsid Attacking Apples (*Neurocolpus nubilis*), by H. G. Crawford (pp. 79-88); The Founding of the Science of Cecidology, by A. Cosens (pp. 88-93); The Army Cutworm in Southern Alberta, by E. H. Strickland (pp. 93-97); Life Zones in Entomology and Their Relation to Crops, by H. T. Fernald (pp. 97-101); Some Notes Regarding Nose and Other Botflies, by W. Lochhead (pp. 102-108); The Seasonal Prevalence of *Hypoderma bovis* in 1915, Together with Observations on the Terrifying Effect *H. bovis* Has Upon Cattle, and Lesions Produced by the Larva, by S. Hadwen (pp. 108-119), noted on page 482; Progress of Entomology in Canada During 1915, by C. G. Hewitt (pp. 119-123); The Life History of *Chermes cooleyi* in Stanley Park, Vancouver, B. C., by R. N. Chrystal (pp. 123-130); The Cabbage Maggot—Autumn Development in British Columbia (*Phorbia brassicæ*) (pp. 130-139) and The Cabbage Maggot in British Columbia (*P. brassicæ*).—The Natural Control by Parasites and Predacious Insects (pp. 140-145), by R. C. Treherne; Some of the Methods Followed in Nova Scotia in Controlling the Brown-tail Moth, by G. E. Sanders (pp. 147-152); Observations on the Brown-tail and Gipsy Moth Situation in Relation to Canada, by J. D. Tothill (pp. 152, 153); The Work Carried on in the United States Against the Gipsy and Brown-tail Moths, by A. F. Burgess (pp. 153-155); Locust Control Work with Poisoned Baits in Eastern Canada in 1915, by A. Gibson (pp. 156-162); Leaf Rollers At-

tacking Apples, by L. Caesar (pp. 163-178); A Preliminary List of Parasitic Insects Known to Occur in Canada, by R. C. Treherne (pp. 178-193); and The Entomological Record, 1915, by A. Gibson (pp. 194-230).

**Insect pests [in Sitka district],** J. P. ANDERSON (*Alaska Stas. Rpt. 1915*, pp. 41, 42).—It is pointed out that the cabbage maggot is the worst insect enemy of horticultural crops at the Sitka Station, due to its attacking all the cruciferous vegetables. Fifteen or 20 per cent of the apples grown at the station were more or less injured during the year by what is thought to be *Argyresthia conjugella*. A green aphid, troublesome in the greenhouse, was satisfactorily held in check by occasional fumigation with a nicotin paper.

**Report of the entomologist for the year 1915-16,** A. H. RITCHIE (*Ann. Rpt. Dept. Agr. Jamaica, 1916*, pp. 31-34).—The aleyrodid *Aleurocanthus woglumi* is reported to have continued its spread in Jamaica, two of the largest citrus groves on the island having been attacked for the first time. The Florida spray, consisting of Diamond paraffin oil and whale-oil soap, is said to act as an excellent control measure. It is stated that this pest may also be controlled by transferring to citrus trees nests of an undetermined black ant which are naturally built in the forks of branches of the logwood.

Among the enemies of cacao mentioned are the red-banded thrips (*Solcnothrips rubrocinctus*), which causes defoliation and, in the drier localities or during dry periods of the wetter northern estates, rusting of the pods. The emulsion above mentioned (1:50) or blackleaf 40 (1:2000), with 3 lbs. of soap per 100 gal. of spray added as a spreading agent, has been found to be the most satisfactory.

In addition to citrus and cacao pests, mention is also made of the insect enemies of the mango and field crops.

**Some phases of the locust problem,** C. P. LOUNSBURY (*So. African Jour. Sci.*, 12 (1915), No. 2, pp. 33-45).—A discussion of the locust problem, particularly as related to South Africa.

**The cockroach: Its destruction and dispersal,** J. J. H. HOLT (*Lancet [London]*, I, 1916, No. 23, pp. 1136, 1137).—The author has tested the effect of liquid volatile bodies, aromatic oils, coal-tar and paraffin derivatives, dusting powders, and food poisons on the cockroach.

The results of the experiments as a whole seem to indicate "that many of the substances which have been supposed to kill the cockroach have really acted by driving it away and so leading to its disappearance. Such gregarious migrations have been observed but have hitherto been otherwise explained. For quick destruction stoving with bromin or sulphur dioxid is apparently best. For domestic application the daily use of creosote, wood naphtha, or the oil of rosemary, eucalyptus, or citronella placed near the haunts of the cockroaches for two or three weeks should effectually disperse them. Where these are inadmissible on account of their smell, odorless dusting powders may be used. Of these sodium fluorid was found to be the most effective. It is also cheap and keeps indefinitely."

**The green apple bug (*Lygus invitus*) in Nova Scotia,** W. H. BRITAIN (*Ann. Rpt. Ent. Soc. Ontario*, 46 (1915), pp. 65-78, figs. 14).—The observations and experiments during 1915 with *L. invitus* have been summarized as follows:

"The green apple bug is one of the most serious pests of apples and pears in Nova Scotia, though hitherto, owing to its elusive habits, it has not been recognized as such. It is the cause of 'woody pears' and one of the causes of gnarled, twisted apples. It is the most common cause of the continued failure to bear of Nonpareil and certain other varieties of apple. It attacks not only the fruit but also the foliage, stems, and blossoms of apples and pears, and in the adult stage has been known to attack plums.

"The nymphs are frequently caused to drop from the trees by high winds, heavy rains, sprays, etc., and may then either reascend the tree or feed upon the weeds, grass, or clover at its base. Though capable of coming to maturity on the foregoing plants, in the adult state they invariably seek the apple and pear to deposit their eggs.

"In control not only must the tree be thoroughly sprayed to kill as many bugs as possible, but those which have fallen to the ground must be kept there without food until they starve. If the orchard is in sod, or the weeds are abundant, the insects on reaching the adult state will fly to the trees and continue their work. The orchard must, therefore, be kept in a state of clean cultivation, until all the insects have reached the adult state, which will be at the end of the first week in July. The trees must be banded with tree tanglefoot to prevent the reascent of the insects that have fallen to the ground.

"The trees must be properly pruned so that all parts can be readily reached by the spray. Apple trees should be sprayed with blackleaf 40 in the strength of 1 pint to 100 gal., just before the blossoms open and again after they fall; pear trees just after the petals fall and again five days later. A very heavy drenching spray must be applied. The insects are much more easily controlled on pears than on apples, so that with light infestations in this tree spraying alone should be sufficient to control the pest."

Studies of life histories of froghoppers of Maine, H. OSBORN (*Maine Sta. Bul.* 254 (1916), pp. 265-288, pls. 6, figs. 6).—Under the heading of meadow froghoppers the author reports studies made of the meadow froghopper (*Philænus spumarius*), the grass-feeding froghopper (*P. lineatus*), and the angulated froghopper (*Lepyronia quadrangularis*); and under the heading of bush and tree froghoppers, the parallel spittle insect (*Aphrophora parallela*), the alder spittle insect (*Clastoptera obtusa*), the dog-wood spittle insect (*C. proteus*), *C. xanthocephala*, and *Philaronia bilineata* are considered.

It is pointed out that while *P. spumarius* occurs almost entirely on plants other than grasses, *P. lineatus* occurs almost exclusively on grasses, especially timothy and redbtop. *P. spumarius* is widely distributed in the eastern United States as well as in Europe. *P. lineatus* has a wide range in the northern hemisphere, occurring over a wide territory in Europe and North America, but in the United States appears to be distributed especially through the northern portion, occurring from Maine to the Rocky Mountains. The life histories of these species agree very closely, so that one statement will almost answer for the two.

Where the buttercup is present *P. spumarius* seems to gather on it in preference to other plants, though clover is apparently nearly as much affected and there is no doubt that the hoppers must be a distinct factor in the reduction of the formation of the perfect clover heads. The eggs are believed to pass the winter in the meadows where the nymphs are observed in summer, and are probably deposited in the stems of their various food plants or possibly in dead stems or leaves at the surface of the ground. The larvæ hatch in early summer and the nymphs develop rather rapidly, only adults being observed from the middle of July. A frequent rotation from grass to some other crop is thought to be the most effective means of controlling *P. lineatus*. Neither *L. quadrangularis* nor any of the bush and tree froghoppers appears to be of much economic importance.

*Macrosiphum granarium*, the English grain aphid, W. J. PHILLIPS (*U. S. Dept. Agr., Jour. Agr. Research*, 7 (1916), No. 11, pp. 463-480, pls. 3, fig. 1).—As stated by the author, the object of this paper is primarily to record some details of the life history of *M. granarium* (with which *Aphis avenæ* is synonymous) and to discuss the interesting color variations in relation to the sexes.

*M. granarium* is a familiar pest of long standing, widely disseminated throughout the United States wherever small grains are cultivated, and will live and thrive on a number of the wild and cultivated grasses. Observations of its life history and habits made at La Fayette, Ind., and Charlottesville, Va., are recorded, and a tabular report is given of a line of 17 generations at Richmond, Ind., in 1908.

The eggs begin to hatch during the last week in March in the latitude of La Fayette, and continue hatching through the first week in April. Eggs were obtained in Richmond in the fall of 1908 but none hatched the following spring, and of eggs secured in the fall of 1909 at La Fayette only one hatched. From hundreds of eggs secured in the fall of 1910 only about 15 or 20 hatched.

As is common with Aphididæ in general in the latitude of La Fayette, this species reproduces parthenogenetically until October, when the sexes appear and eggs are deposited. While no oviparous females were observed in the fields, the presence of the males indicates that the sexes occur normally on the small grains and on blue grass in the fall. Viviparous females have been carried through the winter out of doors in breeding cages at La Fayette and Charlottesville and have been found on the small grains throughout the fall, in the winter, and again in the early spring, so they doubtless pass the winter both in the egg and as viviparous females in the Northern States. It is doubtful whether eggs and stem mothers normally occur much south of latitude 35° unless it is in higher altitudes.

The aphids remain on the leaves of wheat and other small grains until the heads are formed and then cluster around the tender kernels, sucking the rich sap. Just before harvest, when the plant tissues become hard and tough, all immature individuals become winged and migrate to some of the grasses, where they remain until volunteer grain and fall wheat put in their appearance.

Of the numerous parasitic and predacious enemies of this aphid *Aphidius nigripes* is said to be the most efficient.

The specific effects of certain leaf-feeding Coccidæ and Aphididæ upon the pines, K. B. BROWN (*Ann. Ent. Soc. Amer.*, 9 (1916), No. 4, pp. 414-422, pls. 2).—The author's studies show that the damage to the needles of pine trees by aphid feeding is "(1) from the honeydew fungus, which makes the trees unsightly and interferes with the process of photosynthesis or food manufacture in the needles by shutting off part of the light; (2) by discolored areas from which food has been taken and which have been whitened by admission of air to the cells; (3) by the making of conspicuous, infiltrated spots and causing gum exudation; and (4) inconspicuous damage by the great number of piercings and suckings. This, though usually invisible, is probably more important than the first three taken together.

"The damage to pines by the coccids studied is due to sucking and the enzym action of the saliva injected to assist in this process. The damage consists of the destruction of chlorophyll-bearing cells with a subsequent whitening of the needles. This is followed by the death of the needles in some cases, or occasionally by the production of infiltrated spots that while conspicuous are not of great importance."

Life history of the velvet bean caterpillar (*Anticarsia gemmatilis*), J. R. WATSON (*Jour. Econ. Ent.*, 9 (1916), No. 6, pp. 521-528, pls. 2, figs. 2).—Substantially noted from another source (E. S. R., 35, p. 854).

Concerning the oviposition of infertile eggs and parthenogenesis in the silkworm, A. LÉCAILLON (*Compt. Rend. Acad. Sci. [Paris]*, 162 (1916), No. 6, pp. 234-236).—The oviposition of eggs by infertile females occurred very irregularly. Certain infertile eggs may undergo change in color resembling those that are fertile.

The cochylis, H. FAES and F. PORCHET (In *La Station Viticole Cantonale Vaudoise de Lausanne dès Sa Fondation à Son Transfert à la Confédération Suisse, 1886-1916. Lausanne: Dept. Vaud. Agr., 1916, pp. 56-76*).—This article deals with the manner of combating the caterpillar, the pupa, and the adult, the use of natural enemies in dealing with the cochylis, etc. A discussion of *Eudemis botrana*, etc., follows.

Reducing malaria by reducing the number of Anopheles within buildings, J. ZETEK (*Ann. Ent. Soc. Amer., 9 (1916), No. 3, pp. 275-283, figs. 3*).—The author's observations here reported, which are largely applicable to temporary construction camps in malarious regions, show that screening, traps, and mosquito catching indoors will suffice to keep malaria at a very low rate.

Ronald ROSS and the prevention of malarial fever, W. C. GORGAS and F. H. GARRISON (*Sci. Mo., 3 (1916), No. 2, pp. 133-150, pl. 1*).—Following a historical review of the work relating to the transmission of malaria by mosquitoes, the authors describe at length that of Ross and his demonstration of the rôle of Anopheles in the transmission of malarial parasites.

Syrphidæ of Maine, C. L. METCALF (*Maine Sta. Bul. 253 (1916), pp. 193-264, pls. 9, fig. 1*).—The first part of this bulletin consists of a general account of the Syrphidæ and particularly of the structure of the larvæ of the several types, namely, the aphidophagous, boring, short-tailed filth inhabiting, long-tailed (rat-tailed) filth inhabiting, and microdon types. The economic importance of the larvæ, including their beneficial and injurious habits, the economic importance of the adults, and practical measures for increasing the number of Syrphidæ, are next discussed. A list of 20 species of Syrphidæ reared from eggs in 1915, nine of which have apparently not previously been described in the immature stages, and a list of 39 species of Homoptera attacked by Syrphidæ in Maine as observed in 1915 are next given. Descriptions of life stages and life histories of ten Maine forms studied by the author, together with artificial keys to the known larvæ and pupæ of Syrphidæ, make up the main part of the work. The species thus considered and illustrated are *Pipiza pisticoides*, *Melanostoma mellinum*, *Spherothoria cylindrica*, *Allograpta obliqua*, *Syrphus americanus*, *S. torrus*, *S. nitens*, *Didea fasciata*, *Tropidia quadrata*, and *Syrpitta pipiens*.

A glossary is given of the new or unusual terms used, together with a bibliography of 66 titles.

The attraction of Diptera to ammonia, C. H. RICHARDSON (*Ann. Ent. Soc. Amer., 9 (1916), No. 4, pp. 408-413*).—Substantially noted from another source (E. S. R., 36, p. 156).

A contribution to the knowledge of dipterous larvæ and pupæ, J. C. H. DE MELJERE (*Zool. Jahrb., Abt. System. Geogr. u. Biol. Tiere, 40 (1916), No. 3-4, pp. 177-322, pls. 11*).—This paper describes the larval and pupal stages of some 25 forms.

The transmission of disease by flies, E. A. SWEET (*Pub. Health Rpts. [U. S.], Sup. 29 (1916), pp. 20, pls. 2, figs. 2*).—A general discussion of flies and the rôle which they may play in the transmission of disease, their enemies, and eradivative measures.

*Sciara* maggots injurious to potted plants, H. B. HUNGERFORD (*Jour. Econ. Ent., 9 (1916), No. 6, pp. 538-549, pls. 2*).—"The life history of *Sciara coprophila* requires a period of from 24 to 32 days. The egg stage occupies 6 days, the maggot stage 12 to 14 days or longer, the pupa stage 6 days, and the adults have lived under laboratory conditions about a week.

"The maggots, though omnivorous feeders, are injurious to potted plants through their feeding upon the roots and root hairs. Soils that are moist and rich in manure or dried blood attract the flies and lead to the laying of large

numbers of eggs in these favored situations, the result being that the plants growing in soils of this character are seriously damaged.

"The maggots, though resistant to most insecticides, quite readily succumb to drying. Thus, by letting the soils dry out occasionally, little trouble will be experienced. Where a serious infestation occurs, a judicious drying out of the soils, use of dry sand on top of the dirt, and trap pots of dried blood and earth and sprouting grain used to attract egg laying will effectually control the pest. The maggots and eggs in these trap pots should be destroyed about every two weeks by submerging in boiling water.

The occurrence of two annual generations of the elm leaf beetle (*Galeruca luteola*) and the manner in which they follow one another, A. LÉCAILLON (*Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 13, pp. 481-484*).—In the region of Toulouse the eggs of the elm leaf beetle are deposited on elm leaves during a period of four months, or from the first of May until the first of September. The first generation occurs during May and June, followed by the second during July and August. It is thought possible that the adults of the second generation do not complete their oviposition before hibernating and that oviposition is continued the following spring, and also that certain adults of the third generation may commence to oviposit before hibernation commences.

The dock false worm: An apple pest, E. J. NEWCOMER (*U. S. Dept. Agr. Bul. 265 (1916), pp. 39, pls. 2, figs. 6*).—This pest, the larva of an allantine sawfly (*Amctastegia glabrata*), long known both in Europe and America as an enemy of dock, sorrel, and knotweed, has acquired the habit of boring into mature apples on the tree in September and October to hibernate, thereby destroying their market value. With one exception, no evidence of injury was found that occurred before the apples had practically stopped growing. Apples frequently have three or four, or sometimes even eight, holes in them of varying depths, but contain only one or two worms, or often none at all. In the present paper the author reports at length upon studies of its biology and remedial measures, much of the data being presented in tabular form.

The dock false worm is found all over Europe and in Canada and the northern part of the United States, from the Atlantic to the Pacific. There are four generations annually, each occupying about a month, except the fourth, the larvæ of which hibernate and complete their development the following spring. Only the larvæ of the last generation are known to bore into apples. The ichneumonid parasites reared from overwintering material represent seven distinct species, namely, *Epiurus pterophoræ*, *Spilocryptus* sp., *Anoplex* sp., *Bathymetis* sp., *Bathylthrix* sp., and two species of *Cratocryptus*. Of 268 eggs observed at Wenatchee, Wash., from July 26 to September 8, 11.9 per cent were parasitized by *Trichogramma minuta*. As regards remedial measures, it is pointed out that protection may be afforded by keeping the orchard free of dock and other food plants, or where this is impossible by banding the trees with cotton or some sticky substance the latter part of August, leaving the bands on until after the fruit is harvested.

A list of 37 references to literature on the subject is included.

Observations upon some of the predacious and parasitic Hymenoptera, FYLES (*Ann. Rpt. Ent. Soc. Ontario, 46 (1915), pp. 52-60, figs. 2*).—This paper includes a list of 70 species of Ichneumonidæ taken by the author in the Province of Quebec.

*Syntomaspis druparum*, the apple-seed chalcid, R. A. CUSHMAN (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 11, pp. 487-502, pls. 4, figs. 8*).—This is a report of biological studies of *S. druparum* carried on during parts of the seasons 1914 and 1915 at the laboratory at North East, Pa., and in the field throughout its range, which includes the northern tier of States from Vermont

to Michigan. Reports of observations of this insect in New York by Crosby have been previously noted (E. S. R., 28, p. 654).

The only externally visible effect of infestation is caused by the oviposition puncture, which after a few days appears as a minute scar situated in a small, shallow dimple and from which a discolored line extends to the seed. It is pointed out that frequently injury caused by other insects, particularly the apple red bugs, is attributed to the apple-seed chalcid because at the time the injury is noted it is the only insect present. The author has found nearly every variety of natural fruit, except the largest, to be more or less generally infested at practically every point visited. The Lady apple is apparently the only cultivated variety subject to very serious attack, the ordinary commercial varieties never being infested except in run-down or neglected orchards or when fruit is stunted by the overloading of trees or by the attack of some other insect or disease.

In observations at North East in 1914 the adult did not appear in numbers until after the middle of June, the heaviest emergence occurring during the week of June 22 to 29 and the last on July 5. Oviposition may occur within two days after issuing from the seed and may continue as long as 26 days. The eggs have been observed to hatch in from six to ten days. In 1915 the earliest hatching took place on the seventh day after oviposition, the earliest first molt on the sixteenth day, and the earliest second molt on the twenty-first day, the earliest third molt on the twenty-fifth day, and the earliest last molt on the twenty-ninth day, and the first larva to consume the entire seed contents had done so on the forty-ninth day. The last larva to finish feeding required 57 days. It is said to be not uncommon to find six or seven very young larvæ in a single seed, but on only one occasion was more than one of the fifth instar found within a single seed, the surplus larvæ being killed and eaten by the one which ultimately matures, usually before the fourth instar is reached.

When the larva has consumed its total food supply it very shortly assumes what appears to be the hibernating form. Not all of the larvæ from eggs of a given season finish their development and emerge as adults the following spring; a large percentage (some 55 per cent) of them remain as larvæ within the seeds until the second spring. The larvæ begin to pupate during the latter half of May, the latest pupation apparently taking place from three weeks to a month later. The pupal period is of about four weeks' duration.

Thus far no specific enemies of the apple-seed chalcid have been observed. Control measures include the destruction of all wild seedling apples and wild crab-apple trees in the neighborhood and of all drop fruit and culls for two seasons. Where waste fruit is converted into cider, the pomace should be destroyed.

An efficacious endoparasite of *Chrysomphalus dictyospermi*, A. BERLESE and G. PAOLI (*Redia*, 11 (1916), No. 1-2, pp. 305-307, figs. 2).—A new parasite received from Madeira, here described as *Prospaltella lounsburyi*, is said to attack *C. dictyospermi*. About 60 per cent of the nymphs and 40 per cent of the adults in the material examined were parasitized.

## FOODS—HUMAN NUTRITION.

Fats and their economical use in the home, A. D. HOLMES and H. L. LANG (*U. S. Dept. Agr. Bul.* 469 (1916), pp. 27, figs. 2).—This bulletin summarizes information on the general nature of fats and their digestibility and place in the diet, and describes briefly the different animal and vegetable fats now available for food purposes. Suggestions are given regarding the economical selection of fats and their use for table and culinary purposes. There is also in-

cluded a discussion of the utilization of waste fats and methods of rendering and clarifying fats in the home. To secure economy in the use of fats, emphasis is laid upon the desirability of choosing the fats which are best suited for the purpose in question, of avoiding extravagant use of fats, of the need of care of fats to avoid waste through spoilage, and of the saving and utilization of waste fats, whenever the time and labor involved do not exceed the value of the product.

Results are also reported of preliminary studies made by the authors to determine the temperatures most satisfactory for deep frying in fats. It was found that there was a definite temperature for each fat at which the batter fried soaked the smallest quantity of fat and was at the same time satisfactorily cooked. The optimum temperature was about 360° F. for beef fat, 350° F. for lard, and 390° F. for cottonseed, coconut, and peanut oils. A lowering of the temperature 20° in the case of animal fats and 40° F. for vegetable fats resulted in increasing the quantity of fat absorbed by the batter approximately 25 per cent. These experiments indicate that for successful deep frying vegetable fats should be heated from 30 to 40° F. higher than the animal fats.

Methods of preserving and manufacturing meat products, A. CASSAMAGNAGHI (*Métodos de Conservación y Elaboración de Carnes. Montevideo: National Press, 1916, pp. 23*).—Detailed descriptions are given of the methods used in preserving meats exported from Uruguay. Both chilling and freezing processes are described, as well as methods of preserving by heat and by pickling. It is recommended that an inspection service be established, that the use of meat which has been thawed in the open air be forbidden, and that preserved meats be classified according to the processes which have been used in their preservation.

The food value and uses of poultry, HELEN W. ATWATER (*U. S. Dept. Agr. Bul. 467 (1916), pp. 29, figs. 2*).—This bulletin, which summarizes general and experimental data regarding the food value, selection, and use of poultry, is a revision of an earlier publication on this subject (*E. S. R., 15, p. 701*). The material has been brought up to date and some of it is presented in a different form.

The sanitation of the shellfish industry, H. S. CUMMING (*Jour. Amer. Med. Assoc., 67 (1916), No. 27, pp. 2001-2004*).—The author discusses from a sanitary standpoint the development of the shellfish industry and describes efforts to control the sanitary condition of shellfish. Several suggestions for improving the sanitary quality of shellfish are given.

A preliminary chemical study of the rices of Bihar and Orissa, J. N. SEN (*Agr. Research Inst. Pusa Bul. 62 (1916), pp. 20, pl. 1*).—The results of this investigation show that the composition of these rices is in the main similar to that of other rices, approaching those of Burma more closely than others.

“With an increase in the albuminoid content of husked rice there is a diminution in the quantity of soluble carbohydrates. On the other hand, the low content of albuminoids is associated with increased amounts of soluble carbohydrates. When expressed as percentages of the dry matter the sum of the albuminoids and soluble carbohydrates generally lies between 94 and 95.

“The amount of phosphoric acid in a sample of husked rice is just a little less than half of the minerals present. The amount of potash is about half the quantity of phosphoric acid.

“When rice undergoes polishing it loses much of the oil, or other extract, and the minerals, besides some albuminoids. In the outer layers removed during this process the concentration of phosphoric acid is greater than that of potash, although there is relatively more of both these constituents in the bran than in the polished grain. The nitrogen is more uniformly distributed.

"No relation can at present be traced between the chemical composition and the accepted culinary properties of the different rices."

There is also included a discussion on rice as an article of diet.

North Dakota wheat for 1916, E. F. LADD (*North Dakota Sta. Bul. 119 (1916), pp. 51-61, pl. 1*).—This bulletin constitutes a preliminary report on the milling and bread-producing qualities of the wheat crop for 1916. The results are reported of milling and baking tests on the different grades of wheat, and figures are given showing the receipts per bushel of the various milled products in the case of each grade.

The results of the baking tests showed that the baking quality of all the wheats was good and in general they gave large loaf volume and good texture, although they were not always standard in color. The percentage of flour was found to be much higher for the lower grades of wheat than is generally assumed, and the loaf volume for the lower grades was higher than for higher grades, while the color averaged the equal of the minimum standard for straight flours. Previous work (E. S. R., 32, p. 634) was continued by taking data as to a carload of wheat of the several grades and following it through from the farmer to the consumer. An attempt was made to show specifically what each grade would be valued at according to the systems of grading and marketing prevailing in the several localities. The figures presented indicated that from an investment in low-grade wheat there was a greater total income than for the best wheat on the market.

Science of baking business with special reference to yeast foods, R. M. ALLEN (*Nat. Baker, 21 (1916), No. 250, pp. 45, 46, 48, 50-52, 54-56*).—This article reviews the experimental work which has been done along the lines of fermentation, with special reference to the loss of flour due to fermentation; the nutritive value of yeast; and the conservation of dough materials which can be brought about by the addition of various mineral salts.

Experiments in bread making from different kinds of rye, J. JENSEN and E. H. LUDVIGSEN (*Tidsskr. Plantæavl, 23 (1916), No. 2, pp. 185-232*).—As the result of the experiments with Bretagne and Petkus rye here reported, the following conclusions are drawn:

In the case of the eight samples used, bread of good quality was obtained and not much difference noted in the composition of the raw materials. With the same content of water in the rye no difference was noted in the weight or quality of bread. In the making of the dough the flour from very dry rye took up much more water than that from the less dry samples. The water content in freshly baked bread was essentially the same in all cases, about 36 to 37 per cent. A very good and tasty bread was obtained from rye, after wintering, with a water content of from 16 to 18 per cent.

Bread as a food.—Changes in its vitamin content and nutritive value with reference to the occurrence of pellagra, C. VOEGTLIN, M. X. SULLIVAN, and C. N. MYERS (*Pub. Health Rpts. [U. S.], 31 (1916), No. 15, pp. 935-943*).—As the outcome of some studies on the cause of pellagra in Spartanburg County, S. C., the authors call attention to the changes in the composition of corn and wheat flours which have resulted from the introduction of the roller process, especially the loss of vitamins. They state that laboratory investigations showed that while the corn meal and wheat flour made by the old-fashioned process of grinding the whole grain contained practically all of the vitamins of the whole grain, the highly milled products were deficient in these substances. It was also found that "fowl, the classical experimental animal for the physiological estimation of the vitamin content of foods, will live in perfect health for many months on an exclusive diet of wheat, corn, whole-wheat flour, or so-called 'water-ground' corn meal. If these animals are fed, however, on highly

milled products, they will die within a month or two of polyneuritis, a disease very similar to beri-beri."

As it is impossible to determine the vitamin content of cereal products by isolation of these substances from the natural foods, the authors suggest the use of the total phosphorus content as a fairly accurate index of the relative amounts of vitamins present. While this method does not yield absolute values of the vitamin content of cereal products, it is proposed provisionally for wheat flour, corn meal, and hominy, that "for corn products the minimum  $P_2O_5$  content should not be below 0.5 per cent, that of wheat flour not lower than 1 per cent."

Attention is called to the use of baking soda in the preparation of bread as a factor involved in the reduction of the vitamin content of bread, especially corn bread. The authors state that when sodium bicarbonate is used as a leavening agent the high temperature of the oven liberates carbon dioxide from the sodium bicarbonate and the latter is transformed into sodium carbonate. Experiments by the authors and others have shown the destructive action of alkalis on vitamins, which lose their physiological activity when exposed to alkalis, especially at high temperatures. It is stated that "corn bread made from old-fashioned (whole) corn meal, sweet milk, and soda, when forming the exclusive diet of chickens, leads to symptoms of polyneuritis, whereas corn bread prepared from corn meal, sweet milk, and salt ( $NaCl$ ) does not give rise to any symptoms, and fowls seem to live in perfect health. Chickens which have developed polyneuritis on the corn bread made with sweet milk and soda are cured by the administration of vitamins prepared from various foods. Hence . . . [it may be concluded] that corn bread prepared by means of baking soda without the addition of buttermilk is deficient in certain essential accessory foods (vitamins) and that this deficiency is due to the destructive action of the alkali (baking soda) on the vitamins which were originally contained in these foods."

If, however, sour milk or tartaric acid is combined with the baking soda to neutralize its alkalinity, the use of baking soda is deemed harmless. The authors also state that while the use of baking soda without sour milk will not always prove injurious, bread so made is undoubtedly deficient in vitamins, and when the other dietary components are also deficient in vitamins the composition of bread made with baking soda without the use of sour milk accentuates this dietary deficiency and may lead to an impairment of health.

Among the factors stated as playing a rôle in the reduction of the vitamin content of the diet of the people of Spartanburg County are the decrease in the consumption of the more expensive foods, such as meat, eggs, and milk, which are rich in vitamins and efficient in the prevention and treatment of pellagra; the increase in the consumption of highly milled corn meal and wheat flour; and the use of baking soda in the preparation of bread and its addition to beans and other foods to soften them and shorten the time of cooking.

A study of the dietary conditions of certain communities showed "that a large proportion of the people, especially in mill villages, live on a diet which is deficient from the point of view of its vitamin content. Wheat biscuits made from highly milled wheat flour and corn bread made with baking soda without the addition of buttermilk are the staple articles of diet among the people, and . . . [families were found] in which these foods represented about three-fourths of the entire diet. The fact that the above-mentioned influences, which have undoubtedly reduced the vitamin content of the diet, made themselves felt a relatively short time before the rapid increase in the pellagra in-

vidence in this section of the country furnishes considerable evidence in favor of the vitamin-deficiency theory of pellagra."

**Bread as a food** (*Pub. Health Rpts. [U. S.], 31 (1916), No. 33, p. 2205*).—In this supplementary note to the above article it is stated in part that the data reported in that article were "designed to demonstrate primarily that when a diet poor in essential food elements aside from cereals was constantly used, it appeared likely that if the carbohydrate element contained a liberal amount of the accessory food substances known to be contained in whole grains, the probability of pellagra developing was less than when the starchy element of food was deficient in these substances.

"From the broad view of nutrition it is very probably immaterial what kind of flour is used in making bread provided that an adequate mixed diet is consumed which will supply sufficient of the essential dietary components outside of the cereals contained in the diet."

**Evaporated fruit and vegetables**, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 352 (1916), pp. 25*).—This bulletin reports the results of the inspection of of 180 samples of dried fruits and vegetables. In the case of apples, apricots, etc., determinations were made of the amount of sulphur dioxide present in each sample.

**Coconut products and other substitutes for butter** (*Sci. Amer. Sup., 82 (1916), No. 2129, p. 265*).—In his report to the Council of Hygiene, L. Lindet treats of food fats, including butter and its substitutes and different oils with special reference to prevailing conditions in France. He states that in the south of France cooking is done almost exclusively with olive oil, peanut oil, cottonseed oil, and the like. In reference to substitutes for butter chief interest outside of margarin lies in the use of coconut oil or grease. Within the last few years such products have been introduced under the names of "vegetaline," "cocose," etc. The oil, which is extracted from the copra in France, gives a fat product which, after being chemically treated and deodorized, has a melting point of 25 to 26° C. (77 to 78.8° F.) as compared with 33 to 35° for butter. This is corrected by the addition of fats of higher melting point, such as kauritè, mowhira, or the more solid parts of cottonseed oil.

**Coconut toddy in Ceylon**, K. C. BROWNING and C. T. SYMONS (*Jour. Soc. Chem. Indus., 35 (1916), No. 22, pp. 1138-1142*).—Data are reported regarding the method of drawing, uses, processes of treatment, and composition of so-called toddy or palm juice as drawn from the coconut palm (*Cocos nucifera*) in Ceylon. The juice is used for the production of crude sugar, as a beverage, and for the distillation of a potable spirit.

**Composition of Hungarian wines**, M. VUK (*Kisérlet. Közlem., 19 (1916), No. 2, pp. 289-298*).—The results are reported of the analysis of a number of samples of Hungarian wines from the pressing of 1914, and statistics are given regarding the production and export of these products.

**Mace**, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 349 (1916), pp. 13*).—The work of other analysts showing the composition of mace is reviewed, and the author reports the results of the examination of 175 samples of mace. These included samples of known origin, samples essentially true mace, samples mixed with true and wild mace, and samples variously adulterated. Standards are also outlined for mace.

**Boric acid occurring naturally in some foods**, A. H. SMITH (*Ohio Jour. Sci., 17 (1916), No. 2, pp. 66-68*).—Data are reported regarding the amount of boric acid found in dried fruits (dates, peaches, apricots, prunes, figs, and raisins) and in some samples of sausage. Dates and prunes contained the largest percentage of boric acid, the quantities in the other fruits and in the sausages being insignificant, although measurable.

[Drug analyses], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 4 (1916), No. 9, pp. 195-242).—This bulletin reports the results of the examination of a large number of miscellaneous patent medicines, toilet preparations, etc.

Annual report of the state chemist of Florida, R. E. ROSE (*Fla. Quart. Bul. Dept. Agr.*, 27 (1917), No. 1, pp. 213).—This bulletin reports the results of the examination of 1,511 samples of foods, drugs, citrus fruits, fertilizers, and feeding stuffs made during the year 1916.

Sixteenth annual report of the state food commissioner of Illinois, W. S. MATTHEWS (*Ann. Rpt. State Food Comr. Ill.*, 16 (1915), pp. 181, fig. 1).—This publication reviews the work of the department for the year 1915 and reports data regarding 6,513 samples of miscellaneous food products, as well as the results of inspections of creameries, food-manufacturing establishments, etc. The text is given of standards for foods in force January 1, 1916.

Report of the chief of the bureau of inspection on the enforcement of the pure food law, A. M. G. SOULE (*Agr. of Maine, 1915*, pp. 149-177, pls. 3).—The results are reported of the examination of samples of agricultural seeds, commercial feeding stuffs, commercial fertilizers, fungicides, insecticides, drugs, and foods. Inspections were made of bakeries, bottling establishments, canning factories, etc.

Report of deputy state sealer of weights and measures, E. A. RUSS (*Agr. of Maine, 1915*, pp. 128-148, pls. 3).—The work of the bureau of weights and measures during the year 1915 included the testing of a large number of scales, weights, dry and liquid measures, automatic pumps, etc., and an educational campaign.

Homemade fireless cookers and their use (*U. S. Dept. Agr., Farmers' Bul. 771 (1916)*, pp. 16, figs. 5).—Directions are given for building a fireless cooker from materials found in the home or easily obtainable, together with suggestions for the most satisfactory use of the fireless cooker. Recipes for the preparation of different foods in the fireless cooker are included.

Is vegetarianism based on sound science? M. HELEN KEITH (*Sci. Amer. Sup.*, 82 (1916), No. 2135, pp. 358, 359).—The relative advantages and disadvantages of the vegetarian diet are considered in the light of recent experimental data.

The general conclusion drawn by the author from this evidence is that a meat-free diet is not so safe as a diet containing meat. While in some respects animal and vegetable food constituents are equivalent and replaceable, the selection of a suitable variety from these sources requires special care and probably special attention to the manner of preparation. "It may be said emphatically that the narrow restriction of the diet to cereals leads to serious injury."

The action of sodium citrate and its decomposition in the body, W. SALANT and L. E. WISE (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 27-58).—In the experiments reported a study was made of the presence of citrate in the blood of a number of animals (dogs, cats, rabbits, etc.) when administered by mouth or subcutaneously; the rate of disappearance of citrates from the circulation when injected intravenously; the oxidation of citrates in different animals; and numerous observations on toxicity. The results may be briefly summarized as follows:

Sodium citrate disappeared rapidly from the circulation after intravenous injection, but this was retarded when the doses were repeated, oxidation and elimination being probably much slower when large doses were given at frequent intervals. The amount of citrate eliminated in the urine after subcutaneous injection averaged 12 per cent in the case of rabbits and about 30 per cent in the case of cats.

"The toxicity of sodium citrate when given intravenously depends upon the rate of injection, the fatal dose varying between 0.4 and 1.6 gm. per kilogram (approximately), but about 70 mg. may produce symptoms. Only large amounts of citrate are toxic when ingested. Large doses given subcutaneously showed cumulative action. . . . The toxicity of sodium citrate depends upon the rate of its oxidation in the body, being more toxic for animals in which larger quantities are eliminated unchanged."

Elimination of malates after subcutaneous injection of sodium malate, L. E. WISE (*Jour. Biol. Chem.*, 28 (1916), No. 1, pp. 185-196).—A study was made of the elimination of malates following the subcutaneous injection of sodium malate in the case of laboratory animals (rabbits and cats). The small amounts of malic acid in the urine were estimated by a modification of the Ohta-Yoder method (E. S. R., 26, p. 710), the modification consisting in saturating the urine with powdered uranyl acetate, instead of adding saturated solutions of the reagents.

The experiments showed that sodium malate injected subcutaneously in moderate doses was incompletely destroyed by rabbits and cats, from 3 to 21 per cent being eliminated in the urine in the case of rabbits and 17 to 41.5 per cent in the case of cats. Subcutaneous injections of sodium malate in amounts not exceeding 1 gm. per kilogram of body weight were not followed by nephritis or glycosuria. No symptoms were observed in the case of rabbits, and at most only a slight temporary depression in the case of cats. The injection of large amounts (3.3 gm. per kilogram of body weight) of sodium malate was followed by toxic symptoms, although no effort was made to determine the lowest limit of toxicity.

The behavior of tartaric acid and the tartrates in the animal organism, M. KAHN (*Biochem. Bul.*, 4 (1915), No. 14-15, pp. 398-409).—A summary and digest of experiential data.

### ANIMAL PRODUCTION.

Annual review of investigations in general biology, compiled by Y. DELAGE ET AL. (*Ann. Biol. [Paris]*, 19 (1914), pp. XXXVI+588).—This continues the bibliography previously noted (E. S. R., 33, p. 167), presenting data as to the literature published in 1914, with abstracts of the more important articles.

Animal production, VON OLLECH (*Jahresber. Landw.*, 29 (1914), pp. 180-290).—These pages contain abstracts of German articles on animal production and dairying published during 1914, most of which have been noted from other sources.

The pituitary gland.—Its effect on growth and fission of planarian worms, ROSALIND WULZEN (*Jour. Biol. Chem.*, 25 (1916), No. 3, pp. 625-633).—From experiments reported, the author concludes that a diet of pituitary substance increases the rate of fission in planarian worms regardless of the portion of the gland used or the age of the worms. The growth of the worms is accelerated by a diet of pars glandularis and pars intermedia, provided the diet is begun when the worms are very small. There is indication of a distinction between the substance which produces fission and that which produces growth, and that "the growth-producing substances of pars glandularis and pars intermedia leave the gland by way of the blood vessels of pars glandularis."

The results of some feeding experiments on chicks with the gland showed inhibition in the pituitary-fed chick during the early growth period. This result confirms that of Pearl previously noted (E. S. R., 34, p. 668). When four months old, however, the control stopped growth, while the pituitary-fed cock continued its rapid development and in three weeks had become much

larger and heavier than the control. A difference of time in beginning to crow and marked differences in the general appearance of the pituitary-fed chick were also observed.

**The use of energy values in the computation of rations for farm animals,** H. P. ARMSBY (*U. S. Dept. Agr. Bul. 459 (1916), pp. 29*).—This is a revision of Farmers' Bulletin 346 (*E. S. R., 20, p. 96S*). In the computation of rations for farm animals in this bulletin feeding stuffs are compared on the basis of total dry matter, digestible protein, and net energy value.

**Energy values of red-clover hay and maize meal,** H. P. ARMSBY, J. A. FRIES, and W. W. BRAMAN (*U. S. Dept. Agr., Jour. Agr. Research, 7 (1916), No. 9, pp. 379-387*).—This is a report of experiments conducted at the Pennsylvania Institute of Animal Nutrition, in cooperation with the Bureau of Animal Industry of this Department, upon the net energy values of red-clover hay and corn meal, made for the purpose of clearing up discordant results obtained from these two feeding stuffs in investigations previously reported (*E. S. R., 33, p. 72*).

In these experiments five feeding periods of 21 days each were conducted with a 2-year-old Shorthorn steer weighing about 500 kg. at the beginning of the experiments. In two of the periods clover hay alone was fed in amounts to constitute respectively a submaintenance and a heavy ration, and in the other three periods clover hay and maize meal 1:2 in amounts much below maintenance, approximately maintenance, and a heavy ration, respectively. These experiments were conducted along the line of those previously referred to.

It was found that the metabolizable energy per kilogram of the digested organic matter was 3.52 therms for the clover hay and 3.76 therms for the maize meal, as compared with 3.49 therms and 3.8 therms, respectively, as previously reported. The average increment in heat production caused by the consumption of 1 kg. of dry matter was for clover hay 954 and for maize meal 1,143 calories. When these results are combined with those of previous experiments, the corrected values for the average heat increment per kilogram dry matter are for clover hay 973 and for maize meal 1,289 calories. The average net energy values per kilogram of dry matter obtained by the use of the foregoing averages were for clover hay 981 and for maize meal 1,913 calories.

**Studies of the composition and digestibility of several of the more important meadow grasses,** F. HONCAMP, B. STAU, and H. MÜLLNER (*Landw. Vers. Stat., 87 (1915), No. 4-5, pp. 315-350*).—The chemical composition and the digestion coefficients, as determined in a series of digestion experiments with sheep, are given for the following species: *Lolium perenne*, *L. italicum*, *Dactylis glomerata*, *Phleum pratense*, *Poa pratensis*, *P. trivialis*, *Festuca pratensis*, and *F. rubra*. A chemical study of these and other grasses grown on upland moor, lowland moor, mineral, and starch soils indicated a much higher feeding value for the grass grown on the moor soils. The authors state that, in general, there is little difference in the feeding value of the species studied when grown under comparable conditions.

**[Animal husbandry work in Alaska],** C. C. GEORGESON and M. D. SNODGRASS (*Alaska Stas. Rpt. 1915, pp. 22-24, 26, 79-81*).—The greater portion of the Kodiak Station herd of Galloway cattle was wintered at Kalsin Bay on native hay and silage and oat silage put up the previous year. Three cows with their calves and the herd bull were wintered at Kodiak on native hay and oat silage. Two cows died late in the winter from inflammation of the liver, due perhaps to moldy silage. In the dairy work nine cows were milked and records kept of their performance. The milk was tested for fat and the whole milk was fed to the calves. A few of the cows did fairly well for a beef breed. By

persistent effort the characteristic shyness and nervousness of the Galloway calves and heifers are being overcome.

The station flock of 14 ewes, 4 wethers, and 1 ram was wintered at Kalsin Bay. They were kept in corral and open shed after December 2. Fourteen lambs were dropped during the latter part of April and May, of which 7 ewe lambs and 4 ram lambs were saved. In order to prevent further deprecations by the brown bear the flock was placed on an island near Kodiak for summer pasture. The lambs grew rapidly during the summer months and the ewes kept in prime condition. The clip was of good staple and fairly clean, averaging 7 lbs. per head.

Suggestions are given for future work in the breeding of cattle and horses for the needs of Alaska.

A list of breeders of pure-bred live stock in Montana (*Montana Sta. Spec. Circ. 3 (1916), pp. 23*).—This gives a list of breeders of pure-bred horses and jacks, cattle, swine, sheep, and goats in the State.

The utilization of feed by range steers of different ages.—II, Alfalfa hay and milo maize meal, F. W. CHRISTENSEN, H. H. SIMPSON, and L. FOSTER (*New Mexico Sta. Bul. 103 (1916), pp. 117, figs. 11*).—In the experiment here reported, the plan and details of which were the same as those previously noted (*E. S. R., 32, p. 467*), five steers each of calves, yearlings, 2-year-olds, and 3-year-olds were fed like rations under similar conditions for 120-day periods. The calves and yearlings were used in the 1913 test and the others in the 1915 test. The animals used in 1913 were mostly high-grade Hereford range steers and those in 1915 were largely grade Shorthorns, the 3-year-olds lacking considerably in uniformity of type and condition. The feeds used were first-cutting alfalfa hay and milo maize meal of good quality. Analyses are given of the feeds used each year, and from the proportions of the feed constituents in the residues the amounts of hay and grain consumed were calculated on the basis of crude fiber content.

The average daily gains per head made by the calves, yearlings, 2-year-olds, and 3-year-olds, omitting abnormal and doubtful results, were 1.55, 1.89, 2.12, and 1.57 lbs., respectively, and per 1,000 lbs. of live weight 2.7, 2.21, 2.25, and 1.52 lbs., respectively. The amounts of feed consumed per steer daily were 10.74, 17.77, 19.95, and 19.49 lbs., respectively, and per pound of gain 6.96, 9.57, 9.63, and 12.6 lbs., respectively. Diagrams showing by curves the gains made by each steer are given.

Three sets of digestion trials were also made with the calves and yearlings and two sets with the 2-year-olds and 3-year-olds. In these experiments, which lasted 10 days each, two steers were used from each group. The results, which are tabulated in detail, do not show any appreciable or certain superiority of one age of animals over another as regards digestive powers, nor do they show that any particular animal digested his ration better than others. No direct relation was found between the amounts of feed consumed and the digestive coefficients. However, the rations fed were not heavy. The average percentages of digestibility of the alfalfa hay and milo maize meal ration are given, and the composition of each feed and other data in connection with these digestion trials are tabulated.

A method is given for calculating the digestibility of the components of a ration composed of two or more feeds from the coefficients of digestibility of the feeds when fed in combination, but in different proportions, in two or more trials and when no separate determinations of digestibility of any of the components of the ration have been made. The calculated percentages of digestibility of the alfalfa hay in the 1913 experiment were as follows: Dry matter, 63.71; organic matter, 64.16; protein, 61.28; nonprotein, 100; crude fiber, 41.28;

ether extract, 31.66; nitrogen-free extract, 77.02, and total nitrogen, 68.13. The corresponding percentages for the other experiments were as follows: Alfalfa hay in 1915, 53.81, 55.77, 50.77, 100, 37.96, 40.1, 73.21, and 60.84; milo maize meal in 1915, 74.29, 76.06, 46.46, 100, 67.7, 63.18, 82.03, and 49.43; and milo maize meal in 1915, 76.88, 76.9, 61.83, 100, 30.9, 72.84, 80.33, and 61.42, respectively. Owing to the wide variations obtained the coefficients for the ash were not calculated.

Nitrogen balances secured in connection with the digestion trials show considerable irregularities with the same individuals in successive trials and between the groups of different ages, but it is evident that the calves were gaining in protein at a much more rapid rate than the other steers. In spite of irregularities in the results, the data also suggest that the yearlings gained in protein somewhat faster than the older steers. The estimated amount of energy stored per unit of gain by the 3-year-olds was 2.5 times and by the yearlings and 2-year-olds about twice that of the calves.

The average percentages of dressed beef obtained in the slaughter tests of these steers were as follows: Calves, 57.08; yearlings, 59.24; 2-year-olds, 58.72, and 3-year-olds, 57.59. No distinctive differences were apparent in reference to the wholesale cuts from the various steers. The results of chemical analyses of the cuts of meat from the different groups of steers also showed no decided differences among them. The fat content of the round and shoulder cuts was about the same for the different ages of steers. In quality of meat the yearlings surpassed the calves chiefly on account of the larger amount and better distribution of the fat through the lean and in the firmness of the meat. The meat of the calves and yearlings appeared a little finer in grain and was more tender than that of the 2- and 3-year-olds. All the meat was of good quality.

Some experiments and practical demonstrations in hog feeding at the Delta Branch Experiment Station, G. B. WALKER (*Mississippi Sta. Bul. 177 (1916), pp. 16, figs. 7*).—In a 90-day test in 1914 3 pigs on alfalfa pasture made an average daily gain of 0.59 lb. per head as compared with an average gain of 1.26 lbs. for 3 pigs on alfalfa pasture supplemented by all the shelled corn they would eat once a day. Valuing the gains at 7 cts. per pound alfalfa pasture in this test was worth \$3.71 per head for the 90 days' grazing. In this test corn was worth \$1.23 per bushel as a supplement to alfalfa pasture.

Varying results were secured in 1914 and 1915 in tests of the value of copperas for preventing cotton-seed meal injury to hogs and of the effect of copperas on gains. In the 1914 test 6 3-months-old pigs were fed for 90 days, 3 of the pigs receiving about 3 lbs. shelled corn and 1 lb. cotton-seed meal per head daily, both feeds being fed dry, and the other 3 pigs receiving similar amounts of corn and cotton-seed meal and in addition 1 gal. copperas solution (1 lb. copperas to 50 gal. water) to each pound of cotton-seed meal. All the pigs were kept in dry lots and had access to shade, water, and salt. The lot fed copperas gained 0.33 lb. and the other lot 0.4 lb. per head daily. All the pigs went through the test in good shape, none showing any evidence of injury from cotton-seed meal.

In the first test in 1915, which was similar to the above, one of the 3 pigs fed corn and cotton-seed meal alone was found dead on the forty-third day of the test, another was found dead on the eighty-first day, while the third went through the 90 days apparently in good shape, making an average daily gain of 0.7 lb. The 3 pigs fed copperas lived through the 90 days and made an average gain of 0.71 lb. per head daily.

In the second test in 1915 the pigs were fed the same as in the above except that the self-feeder was used for the lot fed corn and cotton-seed meal. One of the pigs in the self-feeder lot was found dead on the forty-third day. The other

2 went through the 90 days in good shape, averaging 1 lb. per head daily. The 3 pigs fed copperas went through the test in good condition and made an average daily gain of 1.03 lbs. per head. The third test in 1915 was on the same plan as the second except that both lots were allowed to graze on alfalfa at night. All the pigs went through the 90-day test in fairly good shape, those fed copperas making a daily gain of 1.16 lbs. and the others 1.3 lbs. per head.

Three experiments were conducted in 1915 in which self-feeding was compared with hand feeding. In the first of these, with 8-months-old pigs, 3 pigs fed corn and tankage, balanced according to a feeding standard, gained 1.51 lbs. per head daily for 90 days at a cost of 7.45 cts. per pound of gain as compared with 1.58 lbs. at a cost of 5.71 cts. for 3 pigs fed corn and tankage unmixed in a self-feeder. In a similar test with younger pigs for 75 days the hand-fed lot gained 1.54 lbs. per head daily at a cost of 5 cts. per pound of gain, and the self-feeder lot 1.81 lbs. at a cost of 3.73 cts. The third test of this series was similar to the other two except that cotton-seed meal was substituted for tankage and the duration was 60 days. The hand-fed lot gained 1.76 lbs. per head daily at a cost of 4.82 cts. per pound of gain and the self-feeder lot 1.85 lbs. at a cost of 4 cts. In these tests the pigs were kept in dry lots and had access to shade, water, salt, and charcoal.

In an experiment to determine the benefit of either tankage or cotton-seed meal as a supplement to corn and alfalfa pasture 9 pigs averaging 52 lbs. each were fed for 90 days in 3 lots of 3 pigs each. In this test the grain rations were fed in self-feeders. The lot fed corn gained 1.31 lbs. per head daily at a cost of 3.39 cts. per pound of gain, those fed corn and tankage gained 1.35 lbs. at a cost of 3.42 cts., and those fed corn and cotton-seed meal gained 1.25 lbs. at a cost of 3.54 cts.

In a test of black-strap molasses as a substitute for corn 3 pigs fed corn and cotton-seed meal (5:1) gained 1.76 lbs. each daily for 60 days at a cost of 4.82 cts. per pound of gain. During the same period 3 pigs fed molasses and cotton-seed meal (1:1) gained 1.2 lbs. daily per head at a cost of 7.1 cts. per pound of gain. In this test each of the lots received the same amount of cotton-seed meal.

In another test 4 65-day-old pigs from the same litter were fed for 90 days to compare corn alone on dry lot with corn and alfalfa pasture. The pigs in each of the lots had all the corn they would eat, and those in one lot had access to alfalfa pasture at night. The 2 pigs on corn alone gained 0.33 lb. and those on corn and alfalfa pasture 1.22 lbs. per head daily. In this test the pigs on corn alone returned a profit of 75 cts. each and those on corn and alfalfa pasture \$5.69 each, valuing the alfalfa pasture at \$1.

In estimating the cost of gains in the above tests corn was valued at 70 cts. per bushel, tankage \$50 per ton, cotton-seed meal \$25 per ton, and molasses 15 cts. per gallon.

Suggestions are given for the breeding and care of hogs under southern Mississippi conditions.

**Feeding experiment with a mixed feed, O. VON CZADEK** (*Ztschr. Landw. Versuchsw. Österr.*, 19 (1916), No. 2, pp. 62-70).—Analytical data obtained in a feeding experiment with pigs in which a mixed concentrate of meat and blood meals, cereals, and legumes was used in connection with a basal ration are submitted in detailed tabular form.

It is concluded in general that the claim that the concentrate used has a specific nutritional action and a stimulating effect on the digestion of the remainder of the ration is not substantiated by the results of the experiment.

**Distribution of public-service stallions in Wisconsin in 1916, A. S. ALEXANDER** (*Wisconsin Sta. Bul.* 273 (1916), pp. 64, figs. 3).—It is estimated that

there were 712,000 horses in Wisconsin January 1, 1916, with an average value of \$124 each. There was an increase of 7,000 horses in the State during 1915. The percentage of pure-bred stallions continues to increase slightly notwithstanding the fact that few sires were imported during the year.

A directory is given of the owners of public-service stallions and jacks of the State.

Concerning poultry feed values, G. R. and Mrs. SHOUP (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 9, pp. 13-16*).—The authors submit tabular data of tests carried on at the substation showing the palatability and digestibility of 27 feeds used for poultry, together with compiled cost and nutritive value data. The data are also briefly discussed.

Dwarf eggs of the domestic fowl, R. PEARL and MAYNIE R. CURTIS (*Maine Sta. Bul. 255 (1916), pp. 289-328, figs. 7*).—This bulletin gives in less detail the results of a study reported from another source (*E. S. R., 36, p. 73*).

A list of breeders of standard-bred poultry in Montana (*Montana Sta. Spec. Circ. 4 (1916), pp. 17*).—In addition to this list notes are given on the poultry industry of the State.

### DAIRY FARMING—DAIRYING.

Report of the Sixth International Dairy Congress (*Compt. Rend. 6. Cong. Internat. Lait. Bernc, 1914, pp. 334, pls. 6*).—This is the report of the proceedings of the Sixth International Dairy Congress, held at Berne, Switzerland, June 8-10, 1914 (*E. S. R., 30, p. 398*), including the composition of the permanent bureau and various committees of the congress and of the National Committee of Switzerland, the rules of the congress, a list of official delegates, papers and supplementary communications received by the different sections, reports of proceedings of the different sections, resolutions adopted by the congress, social features, and a list of members present.

Judging dairy cows, G. C. HUMPHREY (*Wisconsin Sta. Bul. 274 (1916), pp. 41, figs. 34*).—This bulletin discusses and shows by means of illustrations the visible characteristics of a good dairy cow, including indications of digestive capacity, temperament and blood circulation, and udder development; and some common deficiencies met with in cows. Other points discussed in the bulletin are the importance of type, constitution, and breeding of dairy cows, production records, value of pedigrees, essentials in becoming an expert judge of live stock, use of score cards, and the organization and holding of judging contests. A scale of points is given of each of the leading dairy breeds of cattle, together with an illustration and record of one of the highest producing representatives of each breed in Wisconsin and the record of the world's champion cow of each dairy breed.

[A new world's champion dairy cow] (*Breeder's Gaz., 70 (1916), No. 8, p. 280*).—The 4-year-old Holstein heifer, Queen Piebe Mercedes, recently completed a year's semiofficial test with a production of 30,230.2 lbs. of milk and 1,111.285 lbs. of milk fat. In no month during the year did she produce less than 2,000 lbs. of milk or less than an equivalent of 100 lbs. of butter. Her average fat test for the whole year was 3.68 per cent.

Reducing the cost of milk production, H. L. BLANCHARD (*Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1917), No. 10, pp. 3-6*).—In this article an attempt is made to outline a system of management and feeding by which an ordinary herd of cows with an average annual production of 5,000 to 6,000 lbs. of milk can be made to pay the owner a profit. Using analyses given in Henry's Feeds and Feeding (*E. S. R., 34, p. 261*), the author has calculated and tabulated the approximate milk equivalent of feed produced on one acre by various

crops. Among the suggested uses of the data is a method of determining the live stock capacity of a farm, making the dairy cow the unit.

A review of the milk situation in New York, J. J. DILLON (*Hoard's Dairyman*, 52 (1916), No. 16, pp. 550, 551).—The author reviews briefly the conditions surrounding the milk supply of New York City during the last 40 years and gives rather full information regarding the recent agitation between milk producers and dealers supplying the New York market.

Common sense in dairy inspection, E. KELLY (*Cornell Countryman*, 14 (1916), No. 2, pp. 109-112, fig. 1).—In this article the advantage of educational work in the improvement of milk supplies is emphasized.

In the author's opinion the health department that deals only with the production of sanitary milk and not with the economic problems which face the dairymen is shortsighted. "Profit for the producer is absolutely necessary if clean milk is to be produced for the people in the cities, and it is well for us to have this in mind as we go about the work of dairy inspection."

The grading of milk in small communities, L. R. WILLIAMS (*Amer. Jour. Pub. Health*, 6 (1916), No. 10, pp. 1093-1099).—In this paper the author reviews the progress being made in the campaign on the grading of milk in cities having a population of less than 50,000 and in the villages and smaller communities in New York since the adoption of the state milk code.

The new state dairy law, C. L. ROADHOUSE (*Univ. Cal. Jour. Agr.*, 4 (1916), No. 2, pp. 43, 62, 63, fig. 1).—The objects and provisions of the new California state dairy law which became effective October 1, 1916, are briefly stated.

This law provides that all milk and cream or other milk products except cheese sold in retail trade must either be produced from animals which have passed an official tuberculin test or the milk must be pasteurized. It also provides for the grading and labeling of milk when it is sold in cities where a dairy inspection department is maintained. The author states that it is not the intention of the authorities to attempt the enforcement of the portion of the law which pertains to cream for butter making since this is not included in the heading of the law.

Directions are given for the tuberculin testing of cattle and the pasteurization, grading, and labeling of milk in conformity with this act.

The heat resistance of nonspore-forming bacteria in milk, C. GORINI (*Clin. Vet. [Milan]*, 39 (1916), No. 15, pp. 445-450).—Summing up his studies on the survival of nonspore-forming bacteria in sterilized milk the author states that this phenomenon is due either to the presence of a species or race of microbes possessing exceptional heat-resisting qualities, or to the protective influence of enveloping casein which is formed around the individual germs, probably due to the biochemistry of the germ itself, either before or during sterilization.

The value of efficient, commercial pasteurization in safeguarding milk naturally infected with tubercle bacilli, J. TRAUM and G. H. HART (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 5, pp. 678-698).—The authors give a brief review of the most important literature on the thermal death points of tubercle bacilli, and report experiments along this line with samples of milk from a herd consisting entirely of cattle which had reacted to the tuberculin test.

The milk from this herd was pasteurized in a large milk plant in the regular routine manner of pasteurizing, all milk going through the plant. The pasteurization was done in a battery of three large insulated water-jacket vats in which the milk was constantly agitated by means of revolving feed worm coil pipes. Samples were taken of the raw milk from the weigh tank, of the

clarified milk, and of the pasteurized milk, and two or three guinea pigs were inoculated with the cream and sediment obtained by centrifuging each sample.

Of the 24 samples of raw milk used all except one produced tuberculosis in the inoculated guinea pigs, and in this case both inoculated guinea pigs died from septicemia. After clarification 14 samples of the same milk produced tuberculosis in all of the inoculated guinea pigs in all but three cases, and in one of these both inoculated guinea pigs died of septicemia. From the other two samples one guinea pig in each case developed tuberculosis while the other died soon after inoculation. After pasteurization 23 samples of the same milk (plus the required amount of milk or cream to standardize the vat) failed to produce tuberculosis or cause death from inoculation in a single instance. Twelve of these samples were heated above 140° F. and held for a longer period than 20 minutes. The remaining 11 were definitely known to be heated to 140° and held for only 20 minutes.

From these findings the authors conclude (1) that pasteurization at 140° for 20 minutes kills tubercle bacilli in naturally infected milk, (2) that with a properly insulated tank in which the heating and holding are done in the same tank, while the milk is being constantly agitated, one can produce and hold the temperature of all the contained milk at the desired point and for the desired length of time, and (3) that clarification of milk naturally infected with tubercle bacilli fails to render it innocuous to guinea pigs.

In these tests it was found that tubercle bacilli were not destroyed in milk samples preserved with 1 per cent boric acid. Such preservation was sufficient to allow samples to be shipped considerable distances without their undergoing undesirable changes which interfere with laboratory examinations and guinea-pig inoculations.

Comparison of the rate of multiplication of bacteria in raw milk with the rate in pasteurized milk, P. W. ALLEN (*Jour. Infect. Diseases*, 19 (1916), No. 5, pp. 721-728, figs. 7).—In the experiments reported aseptically drawn milk was obtained from cows with a low udder bacterial content and 200-cc. samples were measured out. One portion was pasteurized and the other was not. After pasteurization the treatment of the two portions was the same. Parallel samples in a part of the series were inoculated with *Bacterium lactis acidi* from Ericsson's butter culture in sufficient quantities to mask the effect of the udder organisms. Into each of the samples of the remaining series was inoculated by means of a special pipette one chromogenic bacterium which, on account of the extreme color, could be easily distinguished from the udder organisms. The plate counts of the different samples are tabulated and graphs are given of parallel samples of most of the series.

It was found that raw milk, as compared with pasteurized milk, exerts a powerful suppressing influence on the multiplication of certain bacteria. When *B. lactis acidi* is accustomed to the milk of a certain cow, however, apparently no killing off of this organism takes place in freshly drawn milk. When a single cell of certain pronouncedly chromogenic kinds of bacteria is added to fresh milk, the organism is found plentifully in the milk after 16 hours at 20° C., the injurious action of freshly drawn milk not being sufficiently intense to kill the one bacterial cell. After pasteurization, the organisms which remain in the milk and those which are able to get into it find conditions more favorable for their rapid multiplication than before pasteurization.

The relation of lactic acid bacteria to milk of different degrees of freshness, A. VOITKEVICH (A. WOJTKIEWICZ) (*Věstník Bakt. Agron. Sta. V. K. Ferrein*, No. 22 (1916), pp. 55-79).—The author takes exception to the conclusions of Paraschtschuk (*E. S. R.*, 31, p. 506) that certain species of lactic-acid bacteria develop more rapidly in fresh milk than in milk which is not fresh.

In the investigations reported *Bacillus bulgaricus*, *Streptococcus hollandicus*, and three varieties of *Bacterium lactis acidi* were used. It was found that the majority of these lactic-acid bacteria develop as readily in milk which is not fresh as in fresh milk. Two of the three strains of *B. lactis acidi* showed the reaction of Paraschtschuk, one feebly and the other, isolated from Hansen's dry lactic ferment, very distinctly. These species of bacteria coagulate and acidify old milk more rapidly than fresh milk. The different degrees of sensibility of the bacterial reaction in milk of the same degree of freshness render the Paraschtschuk method unacceptable.

Further researches with Hansen's bacillus show that the increase of protein cleavage products in milk, due to inoculation with peptonizing saprophytes, the addition of peptone, and the action of rennet, augments the acid-forming ability of this microbe. In view of the fact that the preliminary inoculation of fresh milk with a vigorous strain of *B. lactis acidi* followed by sterilization increases the acidity produced by Hansen's bacillus, it is thought that lactic-acid bacteria in their preliminary phase of development in milk cause proteolysis by secreting the proper ectoenzymes. Preliminary inoculation with *B. bulgaricus* produced no effect, indicating that proteolytic enzymes of different species of lactic-acid bacteria are not of the same order.

Advantages of using milk of low bacterial content in studying the phenomena of lactic fermentation, R. BURRI and G. HOHL (*Schweiz. Zentbl. Milchw.*, 5 (1916), Nos. 2, pp. 12-14; 3, pp. 19-23; *abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr.*, 7 (1916), No. 4, pp. 596, 597).—This is a report of the first portion of a series of experiments at the Dairying and Bacteriological Institute of Berne-Liebefeld on the scientific principles underlying the lactic fermentation test. Milk samples with an average bacterial content of from 200 to 300 per cubic centimeter were obtained from four cows by means of aseptic milking. The experiments extended over three different periods, each of several days' duration.
